These are usually suspended in slate vats, owing to the higher voltage used. In the multiple system the anodes are generally cast plates of from 1 inch to $1\frac{1}{2}$ inches in thickness, while in the series system they must be rolled sheets, usually $\frac{1}{4}$ inch thick. The multiple system anodes are sometimes cast directly from the blister furnace or the converter, but they are smoother, more compact, and make less scrap if roughly refined. At the Anaconda works the Bessemer copper is poured into a revolving cylindrical refinery, where it is poled, and thence poured into large ladles mechanically handled, which hold the measured weight of an anode. At other works similar ladles capable of holding 150 ℔ are moved by overhead trolleys. At the Baltimore works Walker's travelling tables present the moulds in rotation to the pouring ladle. The old method of slow hand-ladling has been discarded in the United States works, and the refining furnace, whether for making anodes or casting the cathodes, has been enlarged to a capacity of from 80,000 ℔ to 120,000 ℔ to a charge. The electrolyte is invariably an acidulated solution of cupric sulphate. The current density seldom if ever exceeds 18 ampères to the square foot, and it can be economically raised to that point only when a high temperature and rapid circulation of the electrolyte is maintained. In some rare instances where water power is in excess of requirements, the electrolyte is heated by raising the resistance and by forcing the current through small conductors. With an 18-ampère current, anodes of 1 inch thickness are dissolved in 15 days, and therefore a plant of given size to-day, using a current of high density, turns out at least three times more copper than formerly, when a current density of 6 ampères per square foot was deemed the highest safe maximum limit. The accumulation of dangerous quantities of impurities in the electrolyte is corrected in most works by withdrawing at intervals a given proportion of the whole, recovering its valuable contents and replacing it by pure electrolyte. The metals which it is the aim of most works to recover from copper anodes are copper, gold, and silver. The former is deposited on the cathode, while the precious metals separate and collect as slime, with their valuable or valueless ingredients, in the bottom of the vat, or as a coating on the anodes. Copper is invariably used as the conductor, and almost every works adopts different methods of attaching the electrodes to the permanent conductors.

The only published statement of the cost of refining copper on a large scale is that given in the report of the Anaconda Company, which turns out from its works in Anaconda about 80,000,000 ℔ of copper annually. The total cost, including taxes but not interest on plant, was in 1897–98, $\frac{3}{4}$ cent per pound. This is in excess of the cost on the Atlantic seaboard and in Europe, where fuel and labour are both cheaper. Only electrolytic copper, together with that from Lake Superior, has sufficient purity and conductivity to be used for electrical purposes. It enters the market as cathodes, which are the rough plates, as withdrawn from the tanks, or cast into ingots, wire bars, and cakes. The conductivity of the cathodes is higher than that of the copper cast from them. Copper can be electrolytically deposited on irregular moulds, or as tubes on revolving mandrils. To ensure density, where this is done, agate burnishers travel over the surface of the tube during deposition, as in the Elmore process.

Modern methods in copper smelting have therefore effected enormous economy in time, space, and labour. To-day with pyritic smelting a sulphuretted copper ore, fed into a cupola in the morning, can be passed directly to the converter, blown up to metal, and shipped as 99 per cent. bars by evening—an operation which formerly, with heap roasting of the ore and repeated roasting of the mattes in stalls, would have occupied not less than four months. A large furnace and a Bessemer converter, the pair capable of making a million pounds of copper a month from a low-grade sulphuretted ore, will not occupy a space of more than 25 feet by 100 feet; and whereas, in making metallic copper out of a low-grade sulphuretted ore, one day's labour used to be expended on every ton of ore treated, to-day one day's labour will carry at least four tons of ore through the different mechanical and metallurgical processes necessary to reduce them to metal. (J. Ds.)

**Coppermine,** a river of Mackenzie district, Canada, about 475 miles long, taking its rise in a lake in approximately 110° 20′ W. long. and 65° 50′ N. lat., and flowing south and then north-westward to Coronation Gulf in the Arctic Ocean. It was discovered by Hearne in 1771, and was explored from Point Lake to the sea by Captain (afterwards Sir John) Franklin in 1821.

**Coptic Church.**—Racially the Copts are descendants of the ancient Egyptians, the name *Egypt* meaning "land of the Gypt," as the Copts are to this day called in Arabic. By the Coptic church, therefore, is meant the native church of Egypt or church of Alexandria. Its founder was St Mark, after whom was called the cathedral, which survived the Arab conquest. From St Mark the succession has been maintained to the present time, but not unbroken. Up to the 5th century the church of Alexandria played a part in the Christian world scarcely second to that of Rome: the names of Origen, Athanasius, and Cyril bear witness to her greatness. But in the time of Dioscorus, 25th patriarch, the church, always fond of speculation, was rent asunder by the controversy concerning the single or two-fold nature of our Lord, as stated by Eutyches. The Eutychian doctrine, approved by the council of Ephesus, was condemned by that of Chalcedon in 451. But to this decision, though given by 636 bishops, the Copts refused assent—a refusal which profoundly affected both the religious and the political history of their country. From that moment they were treated as heretics. The emperor appointed a new bishop of Alexandria, whose adherents the Copts styled Melkites or Imperialists, while the Copts were called Monophysites and Jacobites. The court party and the native party each maintained its own line of patriarchs, and each treated the other with bitter hostility. For nearly two centuries strife and persecution continued. The well-meant ecthesis of Heraclius was a failure and was followed by repression, till in 640 the Copts found their opportunity in the Saracen invasion. The fall of the Byzantine empire meant the fall of the Byzantine church, and after some resistance the Copts accepted a change of masters, which gave them religious freedom. The orthodox or Melkite party, consisting mostly of Byzantine Greeks, was swept away, and the double succession of patriarchs practically ceased. True, even in 1901 there was an orthodox patriarch of Alexandria living in Cairo, but he had only a few Greeks for followers, and scarcely a nominal succession has been maintained. But the Coptic succession has been continuous and real.

*History.*

"The most holy Pope and patriarch of the great city of Alexandria and of all the land of Egypt, of Jerusalem the holy city, of Nubia, Abyssinia, and Pentapolis, and all the preaching of St Mark," as he is still called, had originally jurisdiction over all the places named. Jurisdiction over Abyssinia remains, but from Nubia and Pentapolis Christianity has disappeared. The ancient rule is that no bishop is eligible for the patriarchate. The requirement of a period of desert life has so far prevailed that no one but a monk from one of the desert monasteries is now qualified. This rule, harmless perhaps

*Hierarchy.*

when the monasteries were the great schools of learning and devotion, now puts a premium on ignorance, and is disastrous to the church. The patriarch is chosen by an assembly of bishops and elders. The candidate is brought in chains from the desert, and, if only in monk's orders is passed through the higher grades except that of bishop. The patriarch's seat was transferred some time after the Arab conquest from Alexandria to the fortress town of Babylon (Old Cairo), and in modern times it was shifted to Cairo proper. The other orders and offices in the church are metropolitan, bishop, chief priest, priest, archdeacon, deacon, reader, and monk. The number of bishoprics in ancient times was very large—Athanasius says nearly 100. At present there remain ten in Egypt, one at Khartum, and three in Abyssinia.

The numerous remaining churches in Egypt but faintly represent the vast number standing in ancient times.

***Buildings.*** Rufinus says that he found 10,000 monks in the one region of Arsinoe. Later, in 616, the Persians are described as destroying 600 monasteries near Alexandria. Abû Sâlih (12th century) gives a list of churches surviving in his day, and their number is astonishing. The earliest were cut out of rocks and caverns. In the days of Constantine and Justinian basilicas of great splendour were built, such as the church of St Mark at Alexandria and the Red Monastery in Upper Egypt. This type of architecture permanently influenced Coptic builders, but there prevailed also a type, probably native in origin, though possessing Byzantine features, such as the domed roofing. There is no church now standing which bears any trace of the fine glass mosaics which once adorned the basilicas, nor is there any example of a well-defined cruciform ground-plan. But the use of the dome by Coptic architects is almost universal, and nearly every church has at least three domes overshadowing the three altars. The domes are sometimes lighted by small windows, but the walls are windowless, and the churches consequently gloomy. Among the most interesting churches are those of Old Cairo, those in the Wadi Natrûn, and the Red and White Monasteries.

Every church has three altars at the eastern end in three contiguous chapels. The central division is called

***Church fittings.*** the *haikal* or sanctuary, which is always divided from the choir by a fixed partition or screen with a small arched doorway closed by double doors. This resembles the Greek iconostasis. *Haikal* screen and choir screen are often sumptuously carved and inlaid. A marble basin for the mandatum in the nave, and an epiphany tank at the west are common features. The altar is usually built of brick or stone, hollow within, and having an opening to the interior. A wooden altar-slab covered with crosses, &c., lies in a rectangular depression on the surface, and it is used in case of need as a portable altar. Chalice and paten, ewer and basin, crewet and chrismatory, are found as in the western churches. The aster consists of two crossed half-hoops of silver and is used to place over the wafer. The flabellum is used, though now rarely made of precious metal. Some examples of silver-cased textus now remaining are very fine. Every church possesses thuribles—the use of incense being universal and frequent—and diadems for the marriage service. The use of church bells is forbidden by the Moslems, except in the desert, and church music consists merely of cymbals and triangles which accompany the chaunting.

The sacramental wine is usually made from raisins, but the juice must be fermented. Churches even in Cairo

***Rites and ceremonies.*** have a press for crushing the raisins. The eucharistic bread is baked in an oven built near the sanctuary. The wafer is a small loaf about 3 inches in diameter and 1 inch thick, stamped with the trisagion and with crosses. Communion must be received fasting. Confession is required, but of late has somewhat fallen into disuse. Laymen receive in both kinds. The wafer being broken into the chalice, crumbs or "pearls" are taken out in a spoon and so administered, as in the Greek rite. Reservation is uncanonical. Renaudot states that it was permitted in cases of great extremity, when the host remained upon the altar with lamps burning and a priest watching, but it is not now practised, and there is no evidence of any such vessel as a pyx in Coptic ritual. Small benedictional crosses belong to each altar, and processional crosses are common. The crucifix is unknown, for while paintings and frescoes abound, graven images are absolutely forbidden. The liturgy is still read in the extinct Coptic language, but the gospel and lessons are also read in the vernacular Arabic. Seven sacraments are recognized—baptism, confirmation, eucharist, penance, orders, matrimony, and unction of the sick. The chief fasts are those of Advent, of Nineveh, of Heraclius, Lent, and Pentecost. Pilgrimage to Jerusalem is a duty and sometimes a penance.

Vestments are a difficult subject, obscured by writers like Renaudot and Denzinger, who found their statements on written evidence without having visited

***Vestments.*** Egypt. The majority of the Coptic vestments have peculiarities in form and name, not corresponding closely with vestments of western ritual. But the pallium is the symbol of patriarchal office. Cope and chasuble formerly existed, and for both there is pictorial as well as documentary evidence; but the chasuble has disappeared, and the supervestment of the celebrant is now the cope or *burnus*. The dalmatic remains in use and is often enriched with embroidered figures and texts. The *shamlah* and *tailasân* are peculiar vestments, something like an amice. The *patrashîl* corresponds to the Greek *epitrachelion*, and the *kamâs*, or armlets, to *epimanikia*. The girdle is a liturgical vestment and is worn over the dalmatic. Mitre and pastoral staff are used by bishops, although the mitre is not of western shape and resembles rather a crown, as it is in fact called in Arabic.

The whole of the Coptic ritual deserves much fuller study than it has received. Since the 7th century the church has been so isolated as to be little influenced by changes affecting other communions. Consequently it remains in many respects the most ancient monument of primitive rites and ceremonies in Christendom. But centuries of subjection to Moslem rule have much weakened and degraded it. The priesthood are very ill-paid and mostly very ignorant. Among the younger Copts, however, there is now a strong reforming party who are anxious to remove the reproach of the clergy by education, remembering the time when the church of Alexandria was as famous for learning as for zeal. They desire also to resist the serious encroachments of Roman Catholic, American Presbyterian, and other foreign missions upon their ancient faith. Their great need is an enlightened patriarch of strong character, with funds to found a theological college.

**Copyhold.**—Since the publication of the article in the ninth edition of the *Ency. Brit.* the law relating to the

statutory enfranchisement of copyhold, first established by the Copyhold Act, 1841, has been consolidated by the Copyhold Act, 1894. Owing to the incidents attaching to land "holden by copy of court roll according to the custom of the manor" in the shape of fines and heriots, the inability to grant a lease for a term exceeding a year, and to the peculiar rules as to descent, waste, dower, curtesy, alienation, and other matters, varying often from manor to manor and widely differing from the uniform law applicable to land in general, enfranchisement, or the conversion of land held by copyhold tenure into freehold, is often desired. This could and may still be effected at common law, but only by agreement on the part of both the lord and the tenant. Moreover, it was subject to other disadvantages. The cost fell on the tenant, and the land when enfranchised was subject to the encumbrances attaching to the manor, and so an investigation into the lord's title was necessary. In 1841 an Act was passed to provide a statutory method of enfranchisement, removing some of the barriers existing at common law; but the machinery created was only available where both lord and tenant were in agreement. The Copyhold Act, 1852, went further, and for the first time introduced the principle of compulsory enfranchisement on the part of either party. By the Copyhold Act, 1894, which now governs statutory enfranchisement, the former Copyhold Acts, 1841–87, were repealed, and the law was consolidated and improved. Enfranchisement is now effected under this Act, though in certain cases it is also to be obtained under special Acts, such as the Land Clauses Consolidation Act, 1848; and the old common-law method with all its disadvantages is still open. The Copyhold Act, 1894, deals both with compulsory and with voluntary enfranchisement. In either case the sanction of the Board of Agriculture must be obtained; and powers are bestowed on it to decide questions arising on enfranchisement, with an appeal to the High Court. The actual enfranchisement, where it is compelled by one of the parties, is effected by an award made by the board; in the case of a voluntary enfranchisement it is completed by deed. Under the Act it is open to both lord and tenant to compel enfranchisement, though the expenses are to be borne by the party requiring it. The compensation to the lord, in the absence of an agreement, is ascertained under the direction of the board on a valuation made by a valuer or valuers appointed by the lord and tenant; and may be paid either in a gross sum or by way of an annual rent charge issuing out of the land enfranchised, and equivalent to interest at the rate of 4 per cent. on the amount fixed upon as compensation. This rent charge is redeemable on six months' notice at twenty-five times its annual amount. The tenant, even if he is the compelling party, may elect either method; but the lord has not the same option, and where the enfranchisement is at his instance, unless there is either an agreement to the contrary or a notice on the part of the tenant to exercise his option, the compensation is a rent charge. Power is conferred on the lord to purchase the tenant's interest where a change in the condition of the land by enfranchisement would prejudice his mansion house, park, or gardens; while on the other hand, in the interest of the public or the other tenants, the board is authorized to continue conditions of user for their benefit.

*Act of 1894.*

So far the provisions relating to compulsory enfranchisement have been dealt with; but even in the case of a voluntary agreement the lord and tenant are only entitled to accept enfranchisement with the consent of the Board of Agriculture. The consideration in addition to a gross sum or a rent charge may consist of a conveyance of land, or of a right to mines or minerals, or of a right to waste in lands belonging to the manor, or partly in one way and partly in another. The effect of enfranchisement, whether it be voluntary or compulsory, is that the land becomes of freehold tenure subject to the same laws relating to descent, dower, and curtesy as are applicable to freeholds, and so freed from Borough English, Gavelkind (save in Kent), and other customary modes of descent, and from any custom relating to dower, or free-bench, or tenancy by curtesy. Nevertheless, the lord is entitled to escheat in the event of failure of heirs, just as if the land had not been enfranchised. The land is held under the same title as that under which it was held at the date at which the enfranchisement takes effect; but it is not subject to any estate right, charge, or interest affecting the manor. Every mortgage of the copyhold estate in the land enfranchised becomes a mortgage of the freehold, subject though to the priority of the rent charge paid in compensation under the Act. All rights and interests of any person in the land and all leases remain binding in the same manner. On the other hand the tenant's rights of common still continue attached to the freehold; and, without express consent in writing of the lord or tenant respectively, the right of either in mines or minerals shall not be affected by the change. Some other changes are also made by the Act. No creation of new copyholds by granting land out of the waste is permissible, save with the consent of the Board of Agriculture; and it would seem as if the Act had rendered the customary court a very shadowy institution by enacting that a valid admittance of a new copyholder may be made without holding a court.

Under the earlier Acts, machinery to free the land from the burden of the old rents, fines, and heriots was set up, commuting them into a rent charge or a fine. Commutation, however, is never compulsory, and differs from enfranchisement in that, whereas by enfranchisement the land in question is converted into freehold, by commutation it still continued parcel of the manor, though subject to a rent charge or a fine, as might have been agreed. The ordinary laws of descent, dower, and curtesy were, however, substituted for the customs in relation to these matters incidental to the land in question before commutation, and the timber became the tenant's. (JNO. S.)

# COPYRIGHT.

SINCE 1877 the system of international copyright has been remodelled by the Bern Convention; the United States has conferred a species of international copyright on foreign authors; and considerable changes have been made in the English law of copyright.

So far as the English law of copyright in books is concerned the chief developments have been by decisions of the Courts explaining the exact limits to which protection extends. The most marked and certain progress has been in the application of the law of copyright to the periodical press (in 1877 it was not clear whether a newspaper was for all purposes within the Copyright Act), in order to protect within reasonable limits the labour and expenditure of newspapers that obtain for the public the earliest news and arrange it for publication. The old common-law theory that a perpetual copyright existed over literary

work, as laid down by Lord Mansfield, no doubt has been abandoned. But the Copyright Act, 1842, has been liberally construed as to what is a literary work and what is original matter. It is now settled law that a newspaper is a book within the meaning of the Act, and can claim all rights that a book has under the Copyright Act. Thus, at the present time, leading articles, special articles, and even news items are protected. Current prices of stocks and shares, translations, the compilation of a directory, summaries of legal proceedings, and other similar literary work, so far as the literary form, the labour, and money are concerned, are equally protected. In short, the test may now be broadly stated to be, whether labour of the brain and expenditure of money have been given for the production; whilst the old requirement of original matter is not strictly maintained, or, at any rate, is broadly interpreted. Thus, the *St James's Gazette* was restrained from making extracts from a descriptive article by Rudyard Kipling in the *Times*, and the *Pall Mall Gazette* protected its cable reports of Australian cricket-matches. The latest leading case, however, on the subject is *Walter* v. *Lane* (decided in the House of Lords, 6th August 1900). The question raised was, whether or not copyright applied under the Act of 1842 in respect of *verbatim* reports of speeches. Four of the law lords, viz., the Lord Chancellor, Lord Davey, Lord James of Hereford, and Lord Brampton, upheld the claim to copyright in such cases, whilst Lord Robertson was the sole dissentient. The point of law was examined by each judge with great care; but the gist of their decision is to be found in the opening sentences of the judgment of the Lord Chancellor (Lord Halsbury), who said:—"My lords, I should very much regret if I were compelled to come to the conclusion that the state of the law permitted one man to make profit out of and to appropriate to himself the labour, skill, and capital of another. And it is not denied that in this case the defendant seeks to appropriate to himself the labour, skill, and capital of another. In the view I take of this case, I think the law is strong enough to restrain what to my mind would be a grievous injustice."

Apart from newspapers, protection has been extended to publications having no literary character; Messrs Maple's furniture catalogue, and the Stock Exchange prices on the "tape" have been awarded the same protection as directories. On the other hand, it has been decided that there is no copyright in a title, though if a new title is so like one with an established reputation that it will mislead the public, it may be restrained, not on grounds of copyright, but as a use of a title akin to common-law fraud. The *Sphere* and *Spear*, titles of misleading similarity, assumed by two weekly periodicals that appeared almost simultaneously in London in 1900—the latter, however, being but short-lived—could not successfully attack each other, because neither had an established reputation when the title of the other was first adopted. The Courts have declined to protect works which are mere copies of railway time-tables, or the "tips" of a sporting prophet, or mechanical devices with no independent literary matter, such as patterns for cutting ladies' sleeves.

A committee of the House of Lords has considered proposals and heard evidence concerning various Bills for the amendment of the law of copyright, both literary and artistic. The general tendency of all the proposals is to increase the protection given to authors and artists, by lengthening the term of protection to thirty years after the death of the author, by increasing the amount of protection given (as by forbidding abridgments, dramatization of novels, and translations), and by increasing the efficacy of the remedies for infringement. Many difficult questions, however, remain for consideration, especially in artistic copyright.

*Plays and Music.*—The only decision of importance affecting the drama has been the "Little Lord Fauntleroy" case, in which the person who dramatized the novel of another without his consent, an operation up to that time believed to be unassailable in law, was attacked successfully, by preventing him from using printed or written copies of the play, either to deposit with the Lord Chamberlain or as prompt-books. In every case where much of the original dialogue of the novel is taken, this stops the production of the dramatization. In music, statutes of 1882 and 1888 have prevented the use of the provisions inflicting penalties for the performance of copyright songs for purposes of extortion, by allowing the Court to inflict a penalty of one farthing and make the plaintiff pay the costs, if justice requires it. Authors reserving the right of public performance are required to print a notice to that effect on all copies of the music. An important decision on musical copyright is the recent case in which it has been held that the reproduction of copyright tunes on perforated slips for an Æolian mechanical organ is not an infringement of the copyright in the tune.

*Artistic Copyright.*—The most striking decisions have been those in the "Living Picture" cases (in which it was decided that *tableaux vivants* are not infringements of the copyright of the pictures from which they are taken), and a series of cases relating to photographs, which were not much in the contemplation of the framers of the Artistic Copyright Act of 1862. It has been decided that the "author" of a photograph is the person who groups and effectively superintends the picture, and not his employer, nor the sun, which has some claims to the title. The private sitter has restrained the photographer from exhibiting or selling the photographs for which he has been paid, but in several cases the celebrity who has sat to a photographer at his request and without payment, has not been allowed to distribute his photograph to newspapers for reproduction without the consent of the photographer. (See Artistic Copyright below.)

*Colonial Copyright.*—The International Copyright Act, 1886, contains provisions designed to extend the benefit of the British Copyright Acts to works first produced in the colonies, while allowing each colony to legislate separately for works first produced within its own limit. The latter permission has been adopted by several of the colonies. The desire of Canadian printers to allow or require copyright works to be reprinted or printed in Canada has given rise to a very difficult controversy. The colonies at present are all included in the system of international copyright established by the Bern Convention hereafter explained.

*International Copyright.*—Until 1886 international copyright in Great Britain rested on a series of Orders in Council, made under the authority of the International Copyright Act, 1844, conferring on the authors of a particular foreign country the same rights in Great Britain as British authors, on condition of their registering their work in Great Britain within a year of first publication abroad. A condition of the granting of each order was that the Sovereign should be satisfied that reciprocal protection was given in the country in question to British authors.

*The Bern Convention.*—As the result of conferences at Bern in 1885 and 1887, this system was simplified and made more general by the treaty known as "The Bern Convention," signed at Bern on 5th September 1887. The contracting parties were the British Empire, Belgium, France, Germany, Italy, Spain, Switzerland, Tunis, and Hayti. Luxemburg, Monaco, Norway, and Japan have since joined. Austria and Hungary have a separate con-

vention with Great Britain, concluded on 24th April 1893. The notable absentees among European powers are Holland and Russia. The basis of the Bern Convention was that authors of any of the countries of the Union, or the publishers of works first published in one of them, should enjoy in each of the other countries of the Union the same rights as the law of that country granted to native authors. The only conditions were that the work should comply with the necessary formalities, such as registration, in the country where it was first published, in which case it was exempt from all such formalities elsewhere; and that the protection required from any country should not exceed that given in the country of origin. The rights conferred included the sole right of making a translation of the work for ten years from its first publication. The Convention was retrospective; that is to say, it applied to copyright works published before its coming into existence, each country being allowed to protect vested interests, or copies already made by others, as it should think best.

The rights of foreign authors in Great Britain rest on legislation giving effect to the Bern Convention, namely, the International Copyright Act of 1886 (49 and 50 Vict. c. 33), and an Order in Council made under that Act, dated 28th November 1887. These confer on the author or publisher of a work of literature or art first published in one of the countries which are parties to the Convention, after compliance with the formalities necessary there, the same rights as if the work had been first published in the United Kingdom, provided that those rights are not greater than those enjoyed in the foreign country.

The rights of British authors in foreign countries rest in each country on the domestic legislation by which the particular country has given effect to its promise contained in the Bern Convention, and are enforced by the courts of that country. The Bern Convention was revised in minor details not affecting its broad principles by a conference meeting in Paris, and Great Britain adopted the results of their labours by an Order in Council dated 7th March 1898.

## AMERICAN COPYRIGHT.

An Act of the United States, known as the Act of March 1891, which replaced the Act of July 1870, and which is still in force, constituted the most important modification in copyright law since the original Act of 1790. Under all Acts preceding it, copyright had been granted to "citizens or residents of the United States," the term "resident" having been, in decisions prior to 1891, construed to mean a person domiciled in the United States with the intention of making there his permanent abode. The works of foreigners could thus be reproduced without authorization, and they were so reproduced in so far as there was prospect of financial gain. The leading publishers, however, had from the earliest times made terms with British authors, or with their representatives, the British publishers, for producing authorized American editions. But at most they were only able to secure by this means an advantage of a few weeks' priority over the unauthorized editions, and the good-will of the conscientious buyer; so that if they paid the author any considerable sum, the price of the authorized editions had to be made so high that it was not easy to secure a remunerative sale. The unauthorized editions had the further advantage in competition, that for the purpose of being manufactured more promptly and more economically, they could be and often were issued in an abbreviated and garbled form, an injury which to not a few writers seemed more grievous than the lack of pecuniary profit. In Great Britain, during the first half of the 19th century the copyright law had been so interpreted as to secure recognition of the rights of American authors for such works as were produced there not later than in any other country, so that authors like Washington Irving and Fenimore Cooper secured for a time satisfactory returns; but after 1850 the conditions became the same as in the United States. Unauthorized editions were published, and were often incomplete and garbled.

As from decade to decade the books produced on either side of the Atlantic, which possessed interest for readers of the other side, increased in quantity and in importance, the evil of these unrestricted piracies increased. The injury to British authors was greater only in proportion as the English books were more numerous. The pressure from Great Britain during the last half of the 19th century for international copyright was continuous; and in America it was recognized by authors, by representative publishers, and by the more intelligent people everywhere, that the existing conditions were of material disadvantage. The loss to American authors was direct; and the loss to legitimate American publishers was also clear, in that better returns could be secured by adequate payments for rights that could be protected by law than by "courtesy" payments for authorizations that carried no legal rights. An injury was being done to American literature; for, when authorized editions of American works had to compete against unauthorized and more cheaply produced editions of English works, the business incentive for literary production was seriously lessened. In fiction particularly, authors had to contend against a flood of cheaply produced editions of "appropriated" English books. Equally to be condemned were the ethics of a relation under which one class of property could be appropriated while other classes secured legal protection. On these several grounds efforts had long been made to secure international copyright. Between 1843 and 1886 no less than eleven international copyright Bills were drafted, for the most part at the instance of the copyright associations or copyright leagues. They were one after the other killed in committee. In 1886 the twelfth international copyright Bill was brought before the Senate by Senator Jonathan Chace of Rhode Island, and was referred to the Committee on Patents. In 1887 the American Publishers' Copyright League (succeeding the earlier American Publishers' Associations) was organized, with William H. Appleton as president, and G. H. Putnam as secretary. The Executive Committee of this league formed, with a similar committee of the Authors' Copyright League, a Conference Committee, under the direction of which the campaign for copyright was continued until the passage of the Act of March 1891. Of the Authors' Copyright League James Russell Lowell was the first president, being succeeded by Edmund Clarence Stedman. The secretary during the active work of the League was Mr Robert U. Johnson. Under the initiative of the Conference Committee copyright leagues were organized in Boston, Chicago, St Louis, Cincinnati, Minneapolis, Denver, Colorado City, and other places. The Chace Bill was introduced in the House in March 1888. In May 1890 this Bill, with certain modifications, came before the House, and was there defeated. In March 1891 the same measure, with certain further modifications, secured a favourable vote in the House during the last hour of the last day of the session, was passed by the Senate, and was promptly signed by President Harrison. Thus, after a struggle extending over fifty-three years, the United States accepted the principle of international copyright.

*The Act of 1891.*—The provisions of the copyright law, as amended by the Act of 1891, may be briefly summarized as follows:—

A. *Works of Literature.*—1. Copyright is granted to authors, whether resident or non-resident, for a term of twenty-eight years. A further term of fourteen years is granted to the author if at the expiration of the first term he be still living, or to his widow or children if he be dead. Unless the author survives the first term, or leaves widow or children, the copyright is limited to twenty-eight years. The essential change indicated in this section of the law is the extension of copyright privileges to non-resident producers. 2. In order to secure copyright, all editions of the works of all authors, resident or non-resident, must be entirely manufactured within the United States, the term "manufactured" including the setting of type as well as printing and binding. Prior to 1891 the works of American authors could be put into print on either side of the Atlantic. This manufacturing condition was insisted on by the typographical unions. 3. The country of which a non-resident author is citizen must concede to American authors copyright privileges equivalent to those which it concedes to its own authors. 4. As under the British Act, the works of resident as well as of non-resident authors must be published in the home country not later than in any other country. 5. The regulations previously in force for making the entries of copyright are continued. 6. While the importation of *editions* of the books so copyrighted is prohibited, whether the authors of the same be American or foreign, invoices may be imported of not more than two copies each, said copies being certified to be "for use and not for sale." 7. Foreign periodicals, of which there are no editions printed from type set in the United States, cannot secure an American copyright. The importation of such periodicals is unrestricted except for such numbers as contain reprints of material that has already in some other form secured an American copyright. An English author who copyrights and publishes a volume in the United States, some chapters of which have previously been printed in an English magazine, is not able to prevent the reprinting in the United States of an unauthorized issue of those chapters. In case all the chapters have been printed in a foreign periodical before the publication of the American edition, its American copyright has probably been forfeited. 8. The foreign author has the same control as the native author over translations of such of his books as have been copyrighted in the United States. There is, however, no prohibition of the importation of an edition of a work printed in a language other than that in which it has secured its copyright. 9. Authors or their assigns have the exclusive right to dramatize and to translate any of their works for which copyright has been obtained under the laws of the United States.

B. *Works of Art.*—Foreign artists and designers are accorded the term or terms accorded to foreign authors and to domestic artists. To reproductions in the form of chromos, lithographs, or photographs the condition of American manufacture is attached, but not to the more artistic forms of reproduction, so that foreign authors can control engravings or photogravures of their designs, whether these are manufactured in Europe or in the United States. This provision is held by artists and art publishers of the Continent, who had in past years suffered severely from American appropriations of their productions, to be of special importance. In the case of a painting, drawing, statue, statuary, or a model or design for a work of the Fine Arts, in addition to the title, if there be one, a description and a photograph must be sent.

C. *Music.*—Foreign composers are given the same terms that are accorded to Americans. American manufacture is not necessary, but the condition of reciprocity is the same as in the case of books.

The Act came into effect 1st July 1891. The provisions having to do with international copyright become operative in the case of a foreign state only when the President proclaims that the state has fulfilled the condition of reciprocity. The Act has been put into force with foreign states as follows:—1st July 1891, Great Britain, Belgium, France, Switzerland; 8th March 1892, Germany (by separate treaty); 31st October 1892, Italy; 8th May 1893, Denmark; 15th July 1895, Spain; 20th July 1895, Portugal; 27th February 1896, Mexico; 13th April 1896, Sweden and Norway; 25th May 1896, Chile; 19th October 1899, Costa Rica; 20th November 1899, the kingdom of the Netherlands. In the case of each state the territory covered by the provisions of the law includes the possessions, dependencies, &c. The copyright agreement with Great Britain, therefore, covers the Crown colonies of the empire, such as India, and the independent dominions and states, such as Canada, Australia, &c. An American work which has been duly entered for copyright in Great Britain secures, as a British publication secures, the protection of copyright under the provisions of the Bern convention throughout the territory of the several states that are parties to that convention.

Amendments to the copyright law have been made as follows:—*3rd March 1893*—Producers of article entitled to copyright who had heretofore failed to make delivery, according to the regulation in force, of two copies of the article to be copyrighted, but who had complied with all the other provisions of the Act, and who shall before 1st March 1893 make such delivery, shall be entitled to complete the entry of copyright accordingly. *2nd March 1895*—The penalty to be paid in case of the infringement of the copyright of a photograph made from any object not a work of the Fine Arts shall be limited to a maximum of $5000; and in case of the infringement of a work of the Fine Arts, or of a photograph of the same, to a maximum of $10,000, one-half of said penalties to be paid to the proprietors of the copyright, and the other half to the Treasury of the United States. *1st January 1897*—The performance of dramatic and musical compositions without the consent of the authors involves a liability for damages of not less than $100 for the first performance, and $50 for every subsequent performance as to the Court shall appear just. If the unlawful performance be wilful and for profit, the party responsible shall be guilty of a misdemeanour, and upon conviction shall be imprisoned for a period not exceeding one year. *19th February 1897*—A Bill establishing as the Copyright Department of the Library of Congress a Bureau of Copyrights, the head of which bears the title Register of Copyrights. *3rd March 1897*—Through a modification of section 4963, the responsibility for enjoining the publication or the selling of any article made or imported in violation of the United States copyright laws is placed upon the Circuit Court of the United States in the city of the person complaining of violation.

The salaries of the staff of the Bureau of Copyrights, as established in 1897, amounted to $36,440. The Appropriation Bill passed by Congress in March 1900, increasing the appropriation for the library as a whole, gave the staff of the Copyright Bureau an additional allowance, making the total $51,080. According to the annual statement of the Register of Copyrights of 30th December 1899, the fees received during the twelve preceding months for copyright entries and for the recording of assignments aggregated $60,803.50. The copyright entries comprised 78,370 titles of United States productions, and 8122 titles of foreign productions. These figures include works of art and musical compositions. During the years immediately preceding 1900 the producers of copyright property paid into the United States Treasury from $15,000 to $20,000 annually in excess of the cost of carrying on the Copyright Bureau, and with the increased expenditure for the maintenance of the bureau there will still apparently be a surplus of fees amounting to $10,000. In addition to this, the producers of copyrighted books deliver to the library of Congress a copy required as a voucher for the copyright entry and a further copy for the use of the nation. The books so delivered aggregate from 6100 to 6500 works each year.

The existing American copyright law is defective in several respects, and the following considerations are submitted with a view to its amendment:—

1. The condition that books or works of art must be "manufactured" in America in order to secure American copyright should be eliminated. In case it may not prove practicable to secure the abolition of the manufacturing condition, consideration ought certainly to be given promptly to the just claims of authors whose books are originally produced in some language other than English. There is no logical connexion between the right of an

author or artist to the control of his production and the interests of American workmen; the attempt to legislate for them jointly has brought about no little confusion and inequity. If American working men cannot secure a living in competition with labourers on the other side of the Atlantic, their needs should be cared for under the provisions of the protective tariff. It is, however, the belief of a large number of those who are engaged in the manufacturing of books that, with his advanced methods of work, the skilled American labourer has no reason to dread the competition of European craftsmen. With this manufacturing condition out of the way, there would be nothing to prevent the United States from becoming a party to the Convention of Bern. This would place intellectual property on both sides of the Atlantic on the same footing.

2. The requirement of publication in the United States simultaneously with that in the country of origin, practically debars the authors of France, Germany, and other Continental countries from securing any substantial benefit from the publication of American editions of their works, although these states have extended to American authors, without restrictions, the full advantage of their statutes. The amended law should provide that a work in a foreign language, emanating from a country with which the United States has copyright relations, should be registered for copyright in regular course with the deposit for purposes of identification of two copies of the work in the text of the original, and with the further deposit of a copy of the title-page in English. The law should provide that, in case within a specified term (say twelve months) there should be published a version in English, which had been printed from type set within the United States, and which had in other respects complied with the conditions of the American law, the work should secure the full protection of American copyright, not only for the English version as copyrighted, but for the original text. Under the present conditions the copyrighting of an American edition does not protect the original text from unauthorized translations. If, within the term specified, no edition should be produced for which the conditions of the American Act had been complied with, the right to reproduce the work in English might then fall into the public domain. A provision to such effect, while by no means sufficient to do full justice to Continental authors, would secure for such of these authors, whose books were available for the American reading public, the substantial advantages of American copyright.

3. The term of copyright in force in the United States is shorter than that accorded under the law of any other literature-producing country, excepting Greece. In France and in Russia the term covers the life of the author, and fifty years thereafter. In Germany, since 1834, the term has been for the life of the author and for thirty years thereafter. Under such a term of property the author is in a position to work, not only for himself, but for his children. The United States, with its increasingly important literary interests, ought not to be contented with a shorter term than that in force in Germany. (G. H. P*.)

### Artistic Copyright.

*History.*—Copyright, whether artistic or literary, is the creation of statute. Attempts were made by the first claimants of copyright to place property in ideas on a footing with other forms of property, and to claim for it rights in perpetuity; but in the year 1774 a decision in the House of Lords made it clear that neither public opinion nor law would recognize copyright as property in this sense. Since that time it has been recognized that property in copyright exists only by statute, and that its terms and conditions depend entirely upon Acts of the Legislature, and are liable at all times to alteration at the will of Parliament. Literary authors had protection for their work much earlier than artists. The first literary copyright Act came into existence in the reign of Queen Anne, but it was not until the reign of George II. that the Legislature afforded any protection for the work of artists. The first Artists' Copyright Bill was passed in the interest of William Hogarth, one of the greatest of English painters, who was engraver as well as painter, and who devoted a considerable portion of his time to engraving his own works. No sooner, however, were these published than his market was seriously damaged by the issue of inferior copies of his engravings by other publishers. To protect Hogarth from such piracy an Act was passed on 24th June 1735, which provided that "every person who should invent and design, engrave, etch, or work in mezzotinto or chiaroscuro, any historical or other print or prints, should have the sole right and liberty of printing and representing the same for the term of fourteen years, to commence from the day of the first publishing thereof, which shall be truly engraved with the name of the proprietor on each plate, and printed on every such print or prints." The penalty for piracy was the forfeiture of the plate and all prints, with a fine of 5s. for every pirated print.

Thirty-one years later (1766), in the reign of George III., a second Engraving Act was passed "to amend and render more effectual" the first Act, and "for vesting and securing to Jane Hogarth, widow, the property in certain prints," which extended the protection beyond the designer, who was also engraver, to any person who, not being himself a designer, made, or caused to be made, an engraving from any picture or other work of art. Jane Hogarth, the widow of the painter, found herself nearing the termination of the fourteen years' term of copyright granted by the first Act, with the probability that immediately on its expiry the engravings of her husband then on sale, and on which her livelihood depended, would be immediately pirated. It was mainly to save her from the loss of her livelihood that this second Copyright Bill extended the term of the copyright to twenty-eight years.

The engravers and publishers of the day were not over-scrupulous, and they sought to evade the penalties of the copyright Acts by taking the designs, and adding to them or taking from them, or both, and producing fresh engravings, seeking to make it appear that they were producing new works. These practices assumed such proportions that it became necessary, eleven years after the passing of the second Act (1777), to call upon Parliament to put through another short measure still further to protect the engraver, by prohibiting the copying "in whole or in part" (a clause not contained in the previous Acts), by varying, adding to, or diminishing from, the main design of an engraving without the express consent of the proprietor or proprietors. These three Acts remain in force to the present day. In 1852, in an international copyright Act, it was declared that the Engraving Acts collectively were intended to include prints taken by lithography or any other mechanical process.

In May 1814 an Act was passed to give protection to sculptors. The term of copyright for sculptors was a peculiar one. It was to last for fourteen years, with the proviso that, should the author be still alive, he should enjoy a further period of fourteen years, the copyright returning to him for the second fourteen should he have disposed of it for the first period. It is a condition of copyright with the sculptor that the author must put his name with the date upon every work before putting it forth or publishing it. A curious and interesting point in the interpretation of this Act is that according to the opinion of eminent jurists it is necessary to an infringement of the copyright of a piece of sculpture that the copy of it must take the form of another piece of sculpture; that a photograph, drawing, or engraving of a piece of sculpture is not to be considered a reproduction of it, and is, therefore, not an infringement of the sculptor's copyright.

*The Act of 1862.*—Strange as it may seem, painting was the last branch of the arts to receive copyright protection. The cause of the painters was taken up by the Society of Arts, who endeavoured, in the first instance, to pass an amendment and consolidation Bill dealing with engraving, sculpture, and painting; but, failing in their first effort, they limited their second to an attempt to pass a Bill in favour of painting, drawing, and photography. It was in the year 1862 that this Act, having passed

through Parliament, came into force. The absence of any antecedent protection for the painter is clearly stated in its preamble, which reads as follows: "Whereas by law as now established, the authors of paintings, drawings, and photographs have no copyright in such their works, and it is expectant that the law should in that respect be amended. Be it, therefore, enacted," &c. This preamble makes it clear that there is no copyright in any paintings, drawings, or photographs executed and dealt with before the year 1862; to be exact, 29th July of that year. The duration of the term of copyright in this Act of 1862 differs from its predecessors, by being made dependent on the life of the author, to which life seven years were added. In the Literary Copyright Act there are two terms—the life of the author and seven years, or forty-two years, whichever may prove the longer. In taking a fixed term like forty-two years it is necessary to have something to start from, and with a literary work it was easy to start from the date of publication. But pictures are not published. They may pass from the studio to the wall of the purchaser without being made public in any way. The difficulty was evidently before the author of this Act, and the artist's term was made his life and seven years after his death without any alternative. This term applies equally to photographers. Perhaps no Bill which ever passed through Parliament ostensibly for the purpose of benefiting a certain set of people has failed so completely as has this Bill to accomplish its end. It started by proposing to give copyright to authors of paintings, drawings, and photographs, and it would seem that no difficulty ought to have arisen as to whom such copyright should rightly belong; but the following clause of the Act has introduced confusion into the question of ownership:—

Provided that when any painting, or drawing, or the negative of any photograph, shall for the first time after the passing of this Act be sold, or disposed of, or shall be made, or executed for, or on behalf of any other person for a good or valuable consideration, the person so selling or disposing of, or making or executing the same, shall not retain the copyright thereof unless it be expressly reserved to him by agreement in writing, signed at or before the time of such sale or disposition, by the vendee or assignee of such painting or drawing, or such negative of a photograph, or by the person on whose behalf the same shall be so made or executed; but the copyright shall belong to the vendee or assignee of such painting, or drawing, or such negative of a photograph, or to the person for or on whose behalf the same shall have been made or executed; nor shall the vendee or assignee thereof be entitled to such copyright unless at or before the time of such sale or disposition an agreement in writing, signed by the person so selling or disposing of the same, or by his agent duly authorized, shall have been made to that effect.

That is to say, after promising the author copyright in his work for life and seven years, the Act stipulates that in order to get it the author must, at the time of the first sale or disposition of his picture, obtain a document in writing from the purchaser of the picture, reserving the copyright to the author, and the Act goes on to say that if he does not take this step the copyright becomes the property of the purchaser of the picture, but with the proviso, in order to secure it to him, he must have a document signed by the artist assigning the copyright to him; but if neither of these things is done, and no document is signed, the copyright does not belong to either the artist who sells or the client who buys, and the Act is silent as to whom it does belong to. It has disappeared and belongs to no one. There is no copyright existing in the work for any one. It has passed into the public domain, and any one who can get access to the work may reproduce it. Now, as most purchases are made from the walls of exhibitions, in ninety-nine cases out of a hundred the copyright is absolutely lost. And where the sale is arranged directly between the artist and his client, the difficulty experienced by the artist in raising the question as to whom the copyright shall belong to is so great, owing to the dread lest the mere mention of the signing of a document should cause the selling of the picture to fall through, that in numerous such cases the copyright lapses and becomes public property. Photographers are not affected by this clause, because they do not as a rule sell the negatives they produce, and with them the copyright lies in the negative. They carry on their trade in prints without the question of the negative arising. The picture-dealer, also, who buys a picture and copyright is not subjected to the same disability as the painter. The picture-dealer can sell a picture without saying a word to his client as to the copyright, which he, nevertheless, retains intact; the provision is applicable only to the *first* sale of the work, which, therefore, throws the whole of the disability upon the painter.

The Act gives the copyright of every work executed on commission to the person by whom it is commissioned. It makes it compulsory upon every owner of a copyright that he should register it at Stationers' Hall before he can take any action at law to protect it. The copyright does not lapse if unregistered, but so long as it remains unregistered no action at law can be taken on account of any infringement. A copyright can be registered at any time, even after an infringement, but the owner of the copyright cannot recover for any infringement before registration.

The Act provides for both penalties and damages in the following cases:—

1. For infringing copyright in the ordinary way by issuing unlawful copies.
2. For fraudulently signing or affixing a fraudulent signature to a work of art.
3. For fraudulently dealing with a work so signed.
4. For fraudulently putting forth a copy of a work of art, whether there be copyright in it or not, as the original work of the artist.
5. For altering, adding to, or taking away from a work during the lifetime of the author if it is signed, and putting it forth as the unaltered work of the author.
6. For importing pirated works.

The incongruities of this Act were so apparent that its promoters desired to stop it, feeling that it would be better to have no Bill at all than one which conferred so little upon the people it was intended to benefit; but Lord Westbury, the Lord Chancellor, who had charge of the Bill in the House of Lords, advised them to let it go through with all its imperfections, that they might get the right of the painter to protection recognized. This advice was followed, and the Bill had no sooner become law than a fresh effort was started to have it amended. Year by year the agitation went on, with the exception only of a period when Irish affairs took up all the attention of Parliament, and domestic legislation was rendered impossible. But within the last few years copyright has been again "in the air," and several independent committees have been at work upon the subject; and in 1898 the Copyright Association of Great Britain promoted a Bill, which was introduced into the House of Lords by Lord Herschell. It was a measure designed to deal with all forms of copyright—literary, musical, dramatic, and artistic,—and was remitted by the House of Lords for consideration to a committee, which, having sat for three sessions, decided not to proceed with Lord Herschell's measure, but to treat literature and art in separate Bills. It had under its consideration an artistic Bill, drafted for and presented by the Royal Academy, and a literary Bill and an artistic Bill drafted by the Committee itself. The main proposals in the latter were to give copyright to the author of any artistic work or photograph for a period of life and thirty years, unless the work be commissioned, in which case the copyright was to be the property of the employer, except in the case of sculpture intended to be placed in a street or public place. The Bill provides summary remedies for dealing with pirated works. It omits altogether any reference to registration, and it provides for international copyright.

To sum up the position of artistic copyright, we have five British Acts, three dealing with engraving, one with sculpture, and one with painting, drawing, and photography, and between them there is very little relation.

We have three terms of duration of copyright—28 years for engraving, 14 for sculpture, with a second 14 if the artist be alive at the end of the first, life and 7 years for painting, drawing, or photography. There are two different relations of the artist to his copyright. The sculptor's right to sell his work and retain his copyright has never been questioned so long as he signs and dates it. The painter's copyright is made to depend upon the signing of a document by the purchaser of his work. The engraver and the sculptor are not required to register; but the author's name, and the date of putting forth or publishing, must appear on his work. The painter cannot protect his copyright without registration, but this registration as it is now required is merely a pitfall for the unwary. Designed to give the public information as to the ownership and duration of copyrights, the uncertainty of its operation results in the prevention of information on these very points.

Difficult and complicated as is this whole subject of artistic copyright, it is perhaps not to be wondered at that ignorance of the law on the subject is very widespread, even amongst those who are most interested in its action. One of the commonest beliefs amongst artists is, that all they have to do to secure copyright is to register a picture at Stationers' Hall; but the authorities at Stationers' Hall ask no questions, and simply enter any particulars submitted to them on their printed form. Some artists make a practice, when they send a picture away to exhibition, to fill up one of these forms, reserving the copyright by their entry to themselves, in the belief that, if accompanied by the 1s. fee required by the Stationers' Hall, its entry will reserve the copyright to them, oblivious of the fact that the only thing which can reserve the copyright to them is the possession of a document assigning the copyright to them by the purchaser of the picture. Another useless method of attempting to reserve artists' copyrights is that adopted by the promoters of public exhibitions, with whom it is an almost constant practice to print on some portion of the catalogue of the exhibition a statement that "copyrights of all pictures are reserved," the impression apparently prevailing that a notice of this kind effectively reserves the copyright for the artist while selling his picture from the walls. It, of course, does no such thing, and the copyright of any picture sold in these circumstances, without the necessary document from the purchaser, must be lost to the artist, and pass irrevocably into the public domain.

In a work of art the work itself and the copyright are two totally distinct properties, and may be held by different persons. The conditions differ materially from those of a work of literature, in which as a rule there is no value apart from publication. There is a value in a work of art for its private enjoyment quite apart from its commercial value in the form of reproductions; but when the two properties exist in different hands, the person holding the copyright has no power to force the owner of the work of art to give him access to it for purposes of reproduction; this can only be effected by private arrangement. It has been argued that, as the two properties are so distinct, the owner of the copyright ought to have the right of access to the picture for the purpose of exercising his right to reproduce it. But it is easy to see that it would destroy the value of art property if proprietors knew that at any moment they might be forced to surrender their work for the purpose of reproduction, though for a time only.

There is often a strong sympathy between the artist and the person who buys his picture, and it is not at all unusual, when application is made to the owner of the picture for access to it, for him to submit the question of reproduction to the artist. Although the latter may really have no right in it, it is felt, as a practical matter, that he is largely interested in the character of the reproduction it is proposed to make. Hence the courtesy which is usually extended to him.

Of late years, owing to the increased facilities of reproduction, the practice has become very common of splitting up copyrights and granting licenses in what may be described as very minute forms. It would, of course, be impossible for a publisher to pay an artist the sum at which he values his entire copyright, simply that he might reproduce his picture in the form of a black-and-white block in a magazine, and it has consequently become quite common for the artist to grant a license for any and every particular form of reproduction as it may be required, so that he may grant the right of reproduction in one particular form in one particular publication, and even for a particular period of time, reserving to himself thus the right to grant similar licenses to other publishers. This is apparently not to the injury of the artist; it is probably to his advantage, and it certainly promotes business.

The great obstacle in the way of securing a really good Artistic Bill has been the introduction into it of photography. It was by a sort of accident that the photographer was given the same privileges as the painter in the Bill of 1862. The promoters of the Bill thought that the photographer would be protected by the Engraving Acts which covered prints; but since the photographers feared that, as their prints were of a different character from the prints from a plate, the Engraving Acts might not protect them, it was at the last moment decided to put photography into the Art Bill. The result of this was that the painter lost his chance of copyright on all works executed on commission. Legislators feared that if photographers held copyright in all their works the public would have no protection from the annoyance of seeing the photographs of their wives and daughters exhibited, and sold in shop windows by the side of "professional beauties" and other people, and made articles of commerce. So in the case of commissioned works, the copyright was denied to both painters and photographers, and there seems considerable fear that in any new legislation the attempt to give the same terms to both painter and photographer may lead to great injury and injustice to the public.

The Royal Commission which reported on the subject in 1878 proposed two distinct terms of copyright for painting and photography. The term for the painter was dependent on his life; that for the photographer was a definitely fixed term of years from the date of publication of his photographs; and there can be little doubt that this is the right way to deal with the two branches of copyright. The artist who paints a picture signs it, and there is no difficulty in knowing who is the author of a painting and in whom the term of copyright is vested. But who knows anything as to the authorship of a photograph? In a very large number of cases a photograph is taken by an employee, who is here to-day and gone to-morrow, and even his employer knows nothing of his existence. Of course, it may suit an employer to be able to maintain secrecy as to the authorship of his negative, inasmuch as it enables him to go on claiming copyright fees indefinitely; but it is not to the public interest. In most countries on the Continent a photographer has the fixed term of five years' copyright in an original photograph dating from its publication, which date, together with the name and address of the photographer, has to be stamped on every copy issued. In the public interest some such method of dealing with photographs should be introduced into any new Act. If the choice is between the Continental method and registration, the photographer would probably

choose the former, as it would entail no registration fees.

**Coquelin, Benoît Constant** (1841-——), French actor, was born at Boulogne, January 24, 1841. He was originally intended to follow his father's trade of baker, but his love of acting led him to the Conservatoire, where he entered Regnier's class in 1859. He won a prize for comedy less than a year afterwards, and made his *début* in December 1860 at the Comédie Française, of which house he became a *sociétaire* four years later. His first successes, which were made in classical comedy, were brilliantly sustained during the twenty years that succeeded his election as *sociétaire.* During that time he "created" the leading parts in a number of new plays, including *Gringoire* (1867), *Tabarin* (1871), *Paul Forestier* (1871), *L'Etrangère* (1876), *Jean Dacier* (1877), *Le Monde où l'on s'ennuie* (1881), *Les Rantzau* (1884), and others. In consequence of a dispute with the authorities over the question of his right to make provincial tours in France, he resigned his position at the Comédie Française in 1886. Three years later, however, the breach was healed; and, after a successful series of tours in Europe and the United States, he rejoined the Comédie Française as *pensionnaire* in 1889. He remained there three years, during which time the most notable events were the *début* of his son Jean in 1890, and the production of *Thermidor* (a play suppressed, for political reasons, on the third occasion of its performance), and of a version of *The Taming of the Shrew* under the title of *La Mégère Apprivoisée,* both in 1891. In 1892 he broke definitely with the Comédie Française, and toured for some time through the capitals of Europe with a company of his own.

In 1895 he joined the company at the Renaissance Theatre in Paris, and played there until he became director of the Porte-Saint-Martin Theatre in 1897. There his latest successes have been in *Cyrano de Bergerac* (1897) and *Plus que Reine* (1899). In 1900 he once more undertook an American tour. He has published: *L'Art et le Comédien* (1880), *Molière et le Misanthrope* (1881), essays on *Eugène Manuel* (1881) and *Sully-Prudhomme* (1882), *L'Arnolphe de Molière* (1882), *Les Comédiens* (1882), *L'Art de dire le Monologue* (with his brother, 1884), *Tantuffe* (1884), *L'Art du Comédien* (1894).

**Coquimbo,** a town and important port in Chile, in the province and department of the same name, situated in 29° 57′ 4″ S. lat. and 71° 21′ 12″ W. long. The population in 1895 was 7322. In 1898 it had 5·44 per cent. of the total export trade of Chile, and 3·34 per cent. of the import trade. In the same year it was visited by 484 ships (foreign and coastwise trade), of a total tonnage of 775,981 tons.

**Corato,** a town in the province of Bari, Apulia, Italy, 25 miles west from Bari, with olive and wine production. In the neighbourhood stands the Emperor Frederick II.'s hunting-seat, Castel del Monte. The population (1901) was 41,573.

**Cordoba,** a province in the centre of the Argentine Republic. The official area at the census of 1895 was 62,160 square miles; the population in 1895 amounted to 351,223—urban, 94,760; rural, 256,463. The province is divided into twenty-five departments. In 1895 there were 18,545 farms, 1,070,532 acres planted in cereals, 1,884,926 head of cattle, and 489,926 horses.

**Cordoba,** a city of the Argentine Republic, capital of the province of Cordoba, on the Rio Primero in 31° 25′ S. lat. and 63° 42′ W. long., about 435 miles north-west of Buenos Aires; in communication by rail with all the principal towns of the Republic. It has greatly increased in importance since 1875: the population of the town in 1895 was 42,783; of the suburbs, 11,679. Besides its other educational and scientific institutions, it contains the National Meteorological Bureau of the Argentine, the National Academy of Sciences (1894), a national secondary school, two national schools for teachers, and a good public library. There is a bronze equestrian statue of General Paz, and another of the legislator Dr Sarsfield. Bridges have been constructed to connect the town with two new districts which have sprung up as a result of the introduction of an extensive scheme of irrigation. The water supply is excellent. For internal communication there is an efficient service of electric and other trams.

**Cordova,** a province in the south of Spain, with a population of 420,714 in 1887 and 443,582 in 1897. Its area is 5300 square miles, divided into 16 administrative districts and 74 parishes. The river Guadalquivir divides the province into two very dissimilar portions. On the right bank is the mountainous region of the Sierra Morena, less peopled and fertile than the left bank, with its great plains and slightly undulated country towards the south and south-east in the direction of some spurs of the Sierra Nevada. One of the most picturesque chains of this province is the Sierra de Cordova at some distance from, but along, the right bank of the Guadalquivir, that runs from east-north-east to west-south-west. It waters the richest districts of Cordova, and has many tributaries, one of the most important being El Guadalmellato. The Guadiato and Bembezar are next in importance, and in the northern part of the province are several streams that are tributaries of the Guadiana. The climate is much varied. Snow is to be found for months on the highest peaks of the mountains, mild temperature in the plains except in the few torrid summer months, when rain seldom falls. The latest returns showed that out of 78,204 children of both sexes between the ages of 4 and 14, 36,357 only were on the school registers, and 27,940 attended classes. There are 266 miles of railways, some good first-class state roads, few good provincial and many fair municipal roads. Cordova is one of the provinces of Spain that pays most for the industrial and commercial taxes, though its principal resources and products are agricultural, and its mining interests anything but sufficiently developed. The mines, however, are important. Three lead, 11 argentiferous lead, and 25 coal mines were worked in 1898. Ten silver lead mines at work in 1898 produced 9059 metric tons, valued at £82,123, as compared with 6529 tons, valued at £61,945, in 1897. Three silver lead mines also produced 7439 tons, valued at £18,279, in 1898. The total value at pit's mouth of the output of the mines in 1898 was £257,269, against £193,656 in 1897. The coal mines are almost entirely in the hands of two important companies, Andaluces and Southern of Spain. The Belmez coal-field had in 1898 an output of 383,969 metric tons, valued £156,866, against 316,024 tons, valued £113,772, in 1897. This province also produced in 1898, 29,565 tons of coke, 20,105 of anthracite, 47 metric tons of silver. The most important group of silver lead mines belongs to Anglo-Bilbao companies, and the English lead works smelted 8573½ English tons of lead ore from their Linares mines, producing therefrom 6258 English tons of pig lead. The live stock in the province consists of 11,149 horses, 14,584 mules, 12,923 asses,

25,857 cattle, 214,908 sheep, 61,703 goats, and 54,668 pigs. About 365,000 acres are covered with wheat crops, 228,200 with barley, 50,820 with rye, 62,810 with oats, 36,357 with chick peas, 12,635 with vines, 482,495 with olives.

**Cordova,** the capital of the above province, had a population of 55,615 in 1887, and 55,506 in 1897. The township includes a very extensive territory outside the city proper; in fact, 310,000 acres of area, studded with factories of alcohol, hats, woollen stuffs, and silversmiths' works. The famous leather manufactures have decayed, though some good imitations of the old style are to be met with. Within the area of the town there are lovely gardens, plantations, orange, olive, and lemon groves, and pastures where popular and famed breeds of bulls for the national sport are reared, Cordova being celebrated for its school of bull-fighters. There are many modern public buildings and useful institutions, secondary and primary schools, a school founded in 1590 by the Bishop Pacheco of Cordova for girls, who take the same degrees as the other sex, a school of veterinaries, an academy of sciences, fine arts, and letters, polytechnic school, and an athenæum.

**Corea.** See KOREA.

**Corfu.** See GREECE (*Ionian Islands*).

**Corinth.**—The modern town of New Corinth, capital of an arrondissement in the province of Argolis and Corinth, Greece, is situated on the isthmus of Corinth, near the Bay of Lepanto, Greece, about 3½ miles from the site of the ancient city, at the junction of two railway lines, 57 miles west of Athens and 87 east-south-east of Patras, with which there is also frequent communication by steamer. With the opening of the Corinthian Ship Canal in 1893 its prosperity has somewhat revived. The chief exports are raisins, corn, oil, and silk. Population, 4100.

Corinth, after passing through its various stages called Greek, Roman, Byzantine, and Turkish, survived until 1858 as one of the most considerable towns of Greece, when it was, with the exception of a few houses, levelled to the ground by an earthquake, and New Corinth, a city with broad streets but no old traditions, was founded. A mere handful of the old population remained on the old site, which was marked out for continuous occupation by flowing water and fertile fields. At present a picturesque but poverty-stricken village of somewhat over 1000 inhabitants, mostly of Albanian descent, holds its place among the ruins of former days, and bears the name of Old Corinth. Its most picturesque features are its one gigantic plane tree nourished by the water of Pirene, shading nearly all of the public square, its venerable temple ruin, and Acro-Corinth rising above the village to a height of nearly two thousand feet. The view even from the village, over the Corinthian Gulf, of Parnassus with its giant neighbours on the north, of Cyllene and its neighbours on the west, and of Gerancia on the east, is very fine; but from Acro-Corinth the view is still finer, and is perhaps unsurpassed by any in Greece.

Such were the attractions and the features of Corinth known to those who visited it before 1896. The excavations begun in that year by the American School of Classical Studies at Athens, under the direction of Mr Rufus B. Richardson, have in each succeeding year brought to light important monuments of the ancient city, both of Roman and of Greek times. The outlook at the outset was not hopeful. In the first place, the long and continuous occupation made it appear probable that the slow and remorseless wear of ages had done much more than the destruction of Mummius to obliterate the traces of the ancient monuments; secondly, although there was one landmark of the old Greek city, namely, the old temple ruin, there was no certainty what one of the temples mentioned by Pausanias this was. In fact, by a perverse error, which one topographer after another had handed along, the wrong name of Athena Chalinitis was quite commonly applied to it. The current topography of Corinth was simply a web of conjecture, which gained nothing from the fact that one great name after another was added to the list of its vouchers. The great object to be attained by excavations was the locating of the agora; first, because Pausanias says that most of the important monuments of the city were in and near the agora; and secondly, because he could only thus be used as a guide and authority. As he mentions the monuments in order along the streets radiating from the agora, when the starting-point was once gained, one could hope to identify any foundations found along their various lines. One unsuccessful attempt to locate the agora by excavation had already been made.

*Modern archæological discoveries.*

In the first year's work of the American School twenty-one trial trenches from 10 to 20 feet deep, of varying lengths and scattered over a wide area, were dug, in the hope of finding, if not the agora itself, something which would give a clue that might lead up to the agora. The work was successful. Near the close of the campaign, somewhat less than a quarter of a mile to the north-west of the temple ruin, on the edge of a terrace, the theatre was found. This discovery laid the corner-stone of the topography of Corinth; for the theatre was, according to Pausanias, on the street leading from the agora towards Sicyon, and so to the west of the agora. Another trench, dug across the valley to the east of the temple, revealed a broad pavement of white limestone, extending from the north up the valley towards Acro-Corinth. This was clearly one of the great thoroughfares of the city, and so probably the street mentioned by Pausanias as leading from Lechaeum up to the agora. It was already as good as certain that, by following up this pavement until it was intersected by a line coming from Sicyon past the theatre, one would find oneself in the agora. Even before the agora was found, the temple seemed to take its place as the temple of Apollo, mentioned by Pausanias as "the first monument on your right as you go out of the agora on the street leading towards Sicyon." The limestone pavement yielded in the following year all that it had promised. It was soon seen to end in a flight of thirty-seven marble steps, in their present form of a late date, which lead up to the propylaea of the agora, the buttresses of which are well preserved and agree with the form of a Roman triumphal arch, a form given to the propylaea on the coins of imperial times from Domitian to Commodus. To the east of the staircase and close up against the agora itself, only at a much lower level, was found, buried under 35 feet of earth, the famous fountain, Pirene, tallying exactly with the description of Pausanias, as "a series of chambers resembling grottoes, and bearing a façade of white marble." This two-storey façade of porous stone, with arches opening into the chambers, belonged to the Roman city; and before the time of Pausanias, had received a facing of marble, which has now fallen off but has left traces of itself in the holes by which it was attached and in cartloads of chips which lay in front of the façade. This was not, however, the first form of Pirene. It was built up in front of a more simple Greek façade, which consisted of seven cross walls supporting a conglomerate stratum, and forming six chambers, whose only ornamentation was *antae* at the front end of the cross walls, and on

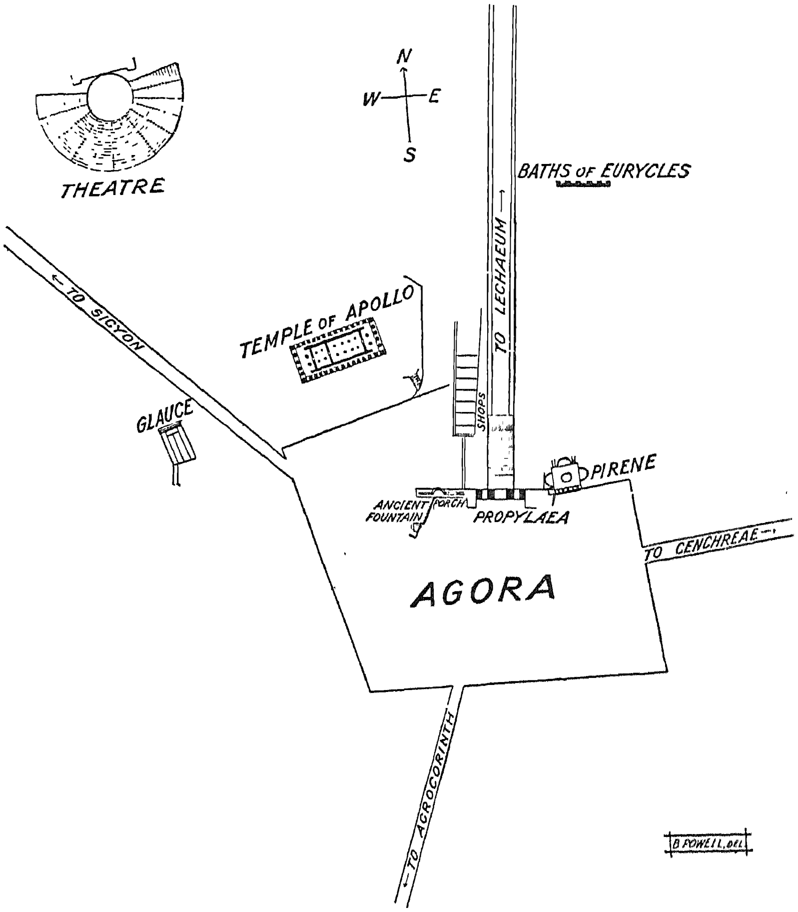
a parapet at the rear single slender Ionic columns between two *antae* supporting an entablature. The chambers were really reservoirs. The water flowed along their backs, poured into them, and then out into a large basin in the open air, enclosed by a large quadrangle with apses on three sides and the façade of the fountain on the other. The whole quadrangle was faced with marble. During the Byzantine period a pretentious but very rough addition was made to this façade by setting five marble columns about four feet in front of the older façade, with heavy architrave blocks running from them back into the façade, which was roughly cut into for the purpose, the object probably being to form a sort of balcony. The columns, the Corinthian capitals, and the bases are all of varying sizes, and, like the architrave blocks, were surely taken from earlier buildings.

barian captive like those found on Roman triumphal arches, is practically entire; and another, its counterpart, is preserved down to the thighs. These figures are not quite like Caryatids and Atlantes, which bear the entablature on their heads. They seem rather to prop up the Corinthian capitals, which rest upon pilasters that form a part of their backs. Two of these stood at each end of a re-entrant curve of the entablature. Two female heads of like proportions belonged to figures with the same architectural functions, bearing straight lines of entablature, and were placed probably to the right and left of the first pair. The building to which they belonged was probably a porch which abutted upon the propylaea on the west, and had a façade like the Septizonium at Rome on a small scale. The foundations of the porch were of a core of *opus incertum*.

To the west of the temple of Apollo was a cube of rock protruding some 10 feet from the ground. This, on being excavated, proved to be the fountain Glauce, an impressive structure entirely cut out of native rock, consisting of four chambers, with a porch of three pillars between two *antae*, approached by a flight of five steps. This falls in line, as it should, between the temple of Apollo and the theatre.

To the north of the propylaea and Pirene, the brick ruins in the middle of the village were explored, and appeared to be the baths of Eurycles, which should lie here on the street to Lechaeum. Some other monuments were identified with more or less probability. But enough has been located with absolute certainty to allow us to speak of a topography of Corinth, not as based on mere conjecture, but on facts; and for the first time a map of the central portion of the ancient city can be drawn.

This is perhaps the greatest result of the excavations, but much more has been accomplished. Vases and fragments of vases have been found, of all periods except the Mycenaean, a gap which will presumably be filled later. On the north side of the hillock on which stands the village schoolhouse there were found several rock-cut vertical shafts, which led into lateral passages used for burial. These contained unpainted vases in considerable quantity, of most varied forms, some of them with incised ornamentation, corresponding closely to the prehistoric pottery of Thera and Hissarlik. A deep digging near the foot of the staircase leading to the propylaea yielded fifteen vases with geometric decoration. In a well about 30 feet below the surface of the road leading westward out of the village square was found a large celebe of old Corinthian style in forty-six fragments, with pieces of several similar vases. A good many so-called Proto-Corinthian vases may be added to the list.



PLAN OF CORINTH SHOWING SITES OF EXCAVATIONS.

The statuary yielded by the excavations is mostly of Roman times. A head of Dionysus crowned with a wreath of ivy, and a round base with a relief of dancing Maenads, surpass in value the many headless statues which have been constantly turning up. But the most important sculptures of this period are a group of colossal statues supporting an entablature, a great part of which has been found. One of these figures, apparently a young bar-

In 1900 was found an ancient Greek fountain in the agora, 25 feet below the present surface of the soil. It is approached through an opening in an enclosure made of metopes and triglyphs, with the painted patterns on them almost as fresh as if they had been painted a year ago. Through the opening a flight of seven steps leads down to a quadrangular room, in the west wall of which are two bronze lion's heads, through the open mouths of which water was once discharged. The whole adjustment and its greater depth than the Roman surroundings prove its great antiquity. It is the only case of an intact Greek fountain, and so of the highest interest in itself, and perhaps still more interesting as an earnest of ancient things still to be discovered when the requisite level is reached.

Among the inscriptions, which are mostly of Roman

date, was one which deserves mention. It is cut in rather rough Greek letters upon a highly ornamented marble block, which in its second use served as the lintel of a Jewish synagogue. The block was broken at both ends, but in the middle appears ΑΓΩΓΗΕΒΡ, *i.e.*, συναγωγὴ Ἑβραίων. Under this lintel without doubt passed and repassed the great Apostle to the Gentiles.

A full account of the various discoveries is given in the volumes of the *American Journal of Archæology* for 1896–1901.

(R. B. R.)

**Corinth, Isthmus of.**—An isthmus of Greece, dividing the Gulf of Corinth from the Saronic Gulf. In 1893 a ship canal was opened through it, with its western entrance about $1\frac{1}{4}$ miles north-east of the little town of New Corinth. It was begun in 1881 by a French company, which ceased operations in 1889, a Greek company completing the undertaking. The canal is 100 feet broad, $3\frac{1}{2}$ miles long, and 26 feet deep. It shortens the journey from the Adriatic to the Piræus by 202 miles, but foreign steamships will not use it, as the narrowness of the canal and the strength of the current at times render the passage dangerous. About 1 mile from its western end it is crossed by the iron bridge of the Athens and Corinth Railway.

**Corinth,** capital of Alcorn county, Mississippi, U.S.A., situated in the north-eastern part of the state, on the Mobile and Ohio and the Southern Railways, at an altitude of 436 feet. During the Civil War, on October 3 and 4, 1862, it was the scene of a severe battle between the Confederates, under Van Dorn, and the Union forces, under Rosecrans, when the former were defeated with heavy loss. Population (1880), 2275; (1890), 2111; (1900), 3661.

**Corinto,** a town in Nicaragua, on the Pacific, the chief port of the Republic. Its harbour is one of the best protected on the coast of Central America, and is part of the ancient port of Realejo. Corinto is the terminus of the railway from Lake Managua, and is regularly visited by the various lines of steamers. It is estimated that it does 59 per cent. of the export and 62 per cent. of the import trade of Nicaragua. Population about 1500.

**Cork,** à maritime county of Ireland, province of Munster.

*Population.*—The area of the administrative county in 1900 was 1,838,921 acres, of which 415,766 were tillage, 971,221 pasture, 1608 fallow, 29,099 plantation, 24,996 turf-bog, 68,997 marsh, 213,688 barren mountain, and 83,546 water, roads, fences, &c. The new administrative county is identical in area with the old judicial county. The population in 1881 was 495,607, and in 1891, 438,432, of whom 219,988 were males and 218,444 females, divided as follows among the different religions:—Roman Catholics, 396,174; Protestant Episcopalians, 35,407; Presbyterians, 2130; Methodists, 3293; and other denominations, 1428. The decrease of population between 1881 and 1891 was 11·54 per cent. The average number of persons to an acre was ·24. Of the total population, 310,851 inhabited the rural districts, being an average of 129 persons to each square mile under crops and pasture. The population in 1901 was 401,813 (Roman Catholics, 366,085; Protestant Episcopalians, 31,411; Presbyterians, 1780; Methodists, 2946; others, 2591), being a decrease of 5·7 per cent. in the East Riding, and of 11·6 per cent. in the West Riding. The following table gives the degree of education in 1891 (excluding the city of Cork):—

| | Males. | Females. | Total. | Percentage. | | |
|---|---|---|---|---|---|---|
| | | | | R. C. | Pr. Epis. | Presb. |
| Read and write . | 121,978 | 113,651 | 235,629 | 69·9 | 91·9 | 95·7 |
| Read only . . | 11,940 | 12,013 | 23,953 | 7·7 | 3·4 | 2·2 |
| Illiterate . . | 32,576 | 35,632 | 68,208 | 22·4 | 4·7 | 2·1 |

In 1881 the percentage of illiterates among Roman Catholics was 32·5. Excluding the city of Cork, in 1891 there were 31 superior schools with 1439 pupils (Roman Catholics 1023, and Protestants 416), and 776 primary schools with 62,093 pupils (Roman Catholics 58,215, and Protestants 3878). The number of pupils on the rolls of the national schools on 30th September 1899 was 74,408, of whom 69,325 were Roman Catholics and 5083 Protestants.

The following table gives the number of births, deaths, and marriages in various years:—

| Year. | Births. | Deaths. | Marriages. |
|---|---|---|---|
| 1881 | 12,253 | 8736 | 1988 |
| 1891 | 9,713 | 8047 | 1759 |
| 1899 | 9,220 | 7030 | 1926 |

In 1899 the birth-rate per 1000 was 21·0, and the death-rate 16·0; the rate of illegitimacy was 1·8 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1899 was 491,932, of whom 255,162 were males and 236,770 females. The following are the chief towns in the county, with their populations in 1891:—Cork, 75,345 (in 1901, 75,978); Queenstown, [illegible]; Fermoy, 6469; Kinsale, 4605; Youghal, 4317; Mallow, 4366; Bandon, 3488.

*Administration.*—The county is divided into seven parliamentary divisions, East, Middle, North, North-East, South South-East, and West, the number of registered electors in 1900 being respectively 6990, 7822, 7463, 7393, 6611, 8339, and 6683. The ratcable value in 1900 was £1,095,885. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury and (to a less extent) of other bodies were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises 7 urban and 18 rural sanitary districts. Under the same Act the city of Cork constitutes a separate county.

*Agriculture.*—The following tables give the acreage under crops, including meadow and clover, and the amount of live stock in 1881, 1891, 1895, and 1900:—

| | Wheat. | Oats. | Barley, Beans, Rye, &c. | Potatoes. | Turnips. | Other Green Crops. | Meadow and Clover. | Total. |
|---|---|---|---|---|---|---|---|---|
| 1881 | 24,597 | 101,933 | 22,280 | 68,709 | 33,784 | 14,914 | 164,307 | 431,445 |
| 1891 | 10,353 | 93,598 | 17,848 | 56,986 | 31,984 | 17,839 | 169,726 | 398,334 |
| 1895 | 4,770 | 99,805 | 19,587 | 53,798 | 34,510 | 20,309 | 184,167 | 416,946 |
| 1900 | 6,840 | 95,572 | 18,639 | 48,109 | 32,569 | 25,113 | 188,900 | 415,766 |

There were also a few acres under flax and rape during these years. For 1899 the total value of the cereal and other crops was estimated by the registrar-general at £2,753,756. The number of acres under pasture in 1881 was 973,567; in 1891, 988,369; and in 1900, 971,221.

| | Horses and Mules. | Asses. | Cattle. | Sheep. | Pigs. | Goats. | Poultry. |
|---|---|---|---|---|---|---|---|
| 1881 | 54,435 | 11,191 | 286,205 | 264,165 | 144,856 | 22,756 | 1,115,668 |
| 1891 | 57,937 | 13,052 | 417,581 | 416,423 | 147,439 | 21,551 | 1,125,955 |
| 1895 | 62,785 | 16,802 | 420,337 | 311,620 | 155,473 | 26,261 | 1,279,991 |
| 1900 | 57,157 | 18,713 | 444,668 | 320,361 | 132,653 | 28,119 | 1,451,516 |

The number of milch cows in 1891 was 174,760, and in 1900, 186,785. It is estimated that the total value of cattle, sheep, and pigs in 1899 was £6,538,272. In 1900 the number of holdings not exceeding 1 acre was 7089; between 1 and 5, 2493; between 5 and 15, 4750; between 15 and 30, 6436; between 30 and 50, 6532; between 50 and 100, 7992; between 100 and 200, 3342; between 200 and 500, 757; and above 500, 67—total, 39,458. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1900, was 2603, amounting to £1,516,880. The number of loans for agricultural improvements sanctioned under sect. 31 of the Land Act, 1881, between 1882 and 1900, was 2559, and the amount issued £189,748, the largest amount in any county of Ireland. The total amount issued on loan for all classes of works under the Land Improvement Acts, from the commencement of operations to 31st March 1900, was £451,533.

*Fisheries.*—There are four deep-sea and coast fishing districts in the county—Youghal, Kinsale, Queenstown, and Castletown Bere—in which, in 1899, 748 vessels were registered, employing 3304 men and boys, and four salmon fishing districts—Cork, Bandon, Skibbereen, and Bantry—in which 777 persons were employed in the same year.

(W. H. PO.)

**Cork,** a maritime city, county and parliamentary borough (returning two members), on the river Lee, 138 miles south-west of Dublin. It is the centre of an extensive railway system, which includes the Great Southern and Western, the Cork, Bandon, and South Coast, the Cork and Macroom Direct, and the Cork, Blackrock, and Passage Railways. The new Protestant

cathedral was completed in 1879. The central tower is 240 feet high. The Parnell bridge over the south channel of the river was opened in 1882. The Crawford Science and Art Schools were opened in 1885, and stand on the site of the old Custom House. A new Protestant church, St Luke's, was erected in 1888. The principal manufactures are distilling, brewing, tanning, chemical manures, tweeds, and friezes, and there is an extensive trade in grain, provisions, and especially butter, the Cork butter market being the chief centre of the trade in Ireland. The port is the most important on the south coast of Ireland, the quays extending for over 4 miles, of which more than 2½ are available for shipping. In all 2368 vessels of 662,086 tons entered in 1899, and 1529 of 402,196 tons cleared. The registered shipping totalled 115 vessels of 21,193 tons. The total foreign and colonial imports for the same year, which included 1,138,870 cwts. of wheat and 2,207,700 of maize, amounted to £1,240,304. There are valuable salmon fisheries on the Lee, in which 370 persons were employed in 1899. In 1898 Cork was constituted one of the six county boroughs which have separate county councils. Population (1881), 80,124; (1891), 75,345, of whom 35,427 were males and 39,918 females, divided as follows among the different religions:—Roman Catholics, 64,561; Protestant Episcopalians, 8620; Presbyterians, 749; Methodists, 867; and others, 548. The population in 1901 was 75,978. In 1891 there were 22 superior schools, with 1771 pupils (1346 Roman Catholics and 425 Protestants), and 58 primary schools, with 11,115 pupils (9597 Roman Catholics and 1518 Protestants). The percentage of illiterates among Roman Catholics was 18·0; among Protestant Episcopalians, 3·2; among Presbyterians, 2·8; and among Methodists, 2·7. The population of the parliamentary borough in 1891 was 97,281 and in 1901, 99,693, and the registered number of electors in 1900, 13,153. The ratable value of the city in 1900 was £173,656. (W. H. PO)

**Cornelius, Carl August Peter** (1824–1874), German musician and poet, son of an actor at Wiesbaden, grandson of the well-known engraver Ignaz Cornelius, and nephew of Cornelius the painter, was born at Mainz, 24th December 1824. In his childhood's days his bent was towards languages, though his musical gifts were carefully cultivated by Scharrer the singer, Panny the Hungarian violinist, and Heinrich Esser. Cornelius the elder, anxious for his son to become an actor, himself taught the boy the elements which can be learnt. These theatrical studies, however, were interrupted early by a visit paid by Peter Cornelius to England as second violin in the Mainz orchestra. On returning home young Cornelius made his stage début as John Cook in *Kean*. But after two more appearances, as the lover in the comedy *Das War Ich* and as Perin in Moreto's *Donna Diana*, he practically abandoned the stage for music, his idea being to become a comic opera composer. In 1843 his father died. Hitherto Cornelius's musical studies had been unsystematic. Now opportunity served to remedy this, for his relative, Cornelius the painter, summoned him in 1844 to Berlin, and enabled him a year later to become a pupil of Dehn, counterpoint and theory generally being worked at laboriously. After leaving Dehn, Cornelius proved his independence by writing a trio in A minor, a quartet in C, as well as two comic opera texts. In 1847 he returned to Dehn and immediately composed an enormous mass of music, including a second trio, 30 vocal canons, several sonatas, a Mass, a Stabat Mater; he also wrote a number of translations of old French poems, which are classics of their kind. In 1852 he first came in touch with Liszt, through his uncle's instrumentality. At Weimar, whither he went in 1852, he heard Berlioz's delightful *Benvenuto Cellini*, a work which ultimately exercised great influence over him. For the time, however, he devoted himself, on Liszt's advice, to further Church compositions, the influence of the Church on him at that time being so great that he applied, but vainly, for a place in a Jesuit college. Still his mind was bent on the production of a comic opera, but the composition was long delayed by the work of translating the prefaces for Liszt's symphonic poems and the texts of works by Berlioz and Rubinstein. Between October 1855 and September in the following year, Cornelius wrote the book of the *Barbier von Bagdad*, and on December 15, 1858, the opera was produced at Weimar under Liszt, and hissed off the stage. Thereupon Liszt resigned his post, and shortly afterwards Cornelius went to Vienna and Munich, and still later came very much under Wagner's influence. Cornelius's *Cid* was completed and produced at Weimar in 1865. For the last nine years of his life (1865–1874) Cornelius was occupied with his opera *Gunlöd* and other compositions, besides writing ably and abundantly on Wagner's music-dramas. In 1867 he became teacher of rhetoric and harmony at the Musik-Schule, Munich, and married Berthe Jung. He died 26th October 1874. Not the least of Cornelius's many claims to fame was his remarkable versatility. Many of his original poems, as well as his translations from the French, rank high. Among his songs, the lovely "Weihnachtslieder" are conspicuous; many of the best are unknown in England, but a great impression has been made in recent years by his "Vatergruft," an unaccompanied vocal work for baritone solo and choir. (R. H. L.)

**Cornell University,** Ithaca, New York, was founded by Ezra Cornell, and opened in 1868. Beside the founder's endowment, it received 990,000 acres of public land, and subsequently gifts from private benefactors. In 1890 its invested funds amounted to $6,756,370, and its total income to $722,210. Its buildings and equipment are valued at $3,242,715, exclusive of the Medical College in New York, valued at $1,000,000. Its library contained, in 1900, 238,376 volumes and 38,400 pamphlets; its average annual growth is 13,000 volumes. The book funds amount to $300,000. The instructing staff numbers 265, including 32 non-resident lecturers, beside 94 in the Medical College in New York City. The total attendance in 1900–1901 (including 83 students in the winter school in Agriculture, and 445 in the summer session of 1899) numbers 3005. Of these, 192 were in the Graduate Department, 744 in the Academic Department, 176 in the College of Law, 336 in the Medical College, 179 in the College of Civil Engineering, 654 in the College of Mechanical Engineering, and 204 in the Colleges of Architecture, Agriculture, Veterinary Medicine, and Forestry. Somewhat more than half of the students come from New York State. Free tuition is annually given to 512 state students, and there are 36 university scholarships of $200, each for two years, awarded by competition to freshmen. Seventeen graduate scholarships of $200 each, 21 fellowships of $500 each, and 2 of $600 are annually granted to graduate students. (See also the articles UNIVERSITIES and EDUCATION.) (J. G. S*.)

**Corneto Tarquinia,** an Italian town in the province of Rome, 13 miles north from Civitavecchia by rail. The church of Santa Maria, in the citadel of the Countess Matilda of Tuscany, has recently been restored. New buildings are the town-hall and municipal museum, particularly rich in archæological treasures, many of them

taken since 1881 out of the cave tombs of the ancient Etruscan town of *Tarquinii*. There is another collection of Etruscan antiquities in the Bruschi palace. Population (1901), 7219.

**Corning,** a city of Steuben county, New York, U.S.A., situated in 42° 08′ N. lat. and 77° 03′ W. long., in the southern part of the state, on Chemung river, at an altitude of 942 feet. It has three railways, the Delaware, Lackawanna, and Western, the Erie, and the New York Central and Hudson River. The surrounding country produces much tobacco. Population (1880), 4802; (1890), 8550; (1900), 11,061.

**Cornu, Marie Alfred** (1841–1902), French physicist, was born on 6th March 1841, and after being educated at the École Polytechnique and the École des Mines, became in 1867 professor of experimental physics in the former institution, where he remained throughout his life. Although he made various excursions into other branches of physical science, undertaking, for example, with Baille about 1870 a repetition of Cavendish's experiment for determining the mean density of the earth, his original work was mainly concerned with optics and spectroscopy. In particular he was known for his redetermination of the velocity of light by Fizeau's method, which he improved in various ways, adding greatly to the accuracy of the results. Among the honours which this achievement won for him were membership of the Academy of Sciences in France and the Rumford medal of the Royal Society in England (both in 1878). In 1899, at the jubilee commemoration of Sir George Stokes, he was Rede lecturer at Cambridge, his subject being the undulatory theory of light and its influence on modern physics; and on that occasion the honorary degree of D.Sc. was conferred on him by the University. He died on 11th April 1902.

**Cornwall,** a peninsular county of England, at the extreme south-west of Great Britain, surrounded on all sides by the sea except on the east and north-east, where it marches with Devon, and the boundary line is formed mainly by the river Tamar.

*Area and Population.*—The area of the ancient and administrative county was given in the census returns of 1891 as 868,208 acres, or 1357 square miles, with a population in 1881 of 330,686, and in 1891 of 322,571, of whom 149,259 were males, and 173,312 females, the number of persons per square mile being 238, and of acres to a person 2·69. In 1901 the population was 322,857. The area of the registration county is 886,372 acres, with a population in 1891 of 318,583, of whom 113,538 were urban, and 205,045 rural.

The following table gives the marriage-, birth-, and death-rates per 1000 persons living, with the percentages of illegitimate births, for a series of years:—

| | 1870-79. | 1880. | 1880-89. | 1890. | 1889-98. | 1899. |
|---|---|---|---|---|---|---|
| Marriage-rate . . . | 12·9 | 12·1 | 13·2 | 13·4 | 13·4 | 13·8 |
| Birth-rate . . . | 30·4 | 29·0 | 28·7 | 26·6 | 27·1 | 25·5 |
| Death-rate . . . | 20·4 | 21·4 | 19·1 | 19·6 | 18·2 | 18·1 |
| Percentage of illegitimacy | 6·3 | 6·8 | 6·1 | 5·7 | 5·4 | 4·9 |

The birth-rate was considerably below the average for England, but the death-rate only a very little below it, while the percentage of illegitimate births was rather high.

*Constitution and Government.*—The ancient county is divided into 6 parliamentary divisions, and it also includes the parliamentary burgh of Penryn and Falmouth, returning one member. The administrative county contains 11 municipal boroughs: Bodmin (5151), Falmouth (12,791), Helston (3198), Launceston (4345), Liskeard (3984), Lostwithiel (1379), Penryn (3256), Penzance (12,432), St Ives (6094), Saltash (2745), and Truro (11,131). The following are urban districts: Camborne (14,700), Hayle (1172), Looe (2454), Ludgvan (2334), Madron (2761), New Quay (1891), Padstow (1546), Paul (5977), Phillack (3979), Redruth (10,324), St Austell (3477), St Just (6119), and Wadebridge (1868). The county is in the western circuit, and assizes are held at Bodmin. The boroughs of Bodmin, Falmouth, Helston, Launceston, Liskeard, Penryn, Penzance, St Ives, and Truro have separate commissions of the peace, and the borough of Penzance has in addition a separate court of quarter sessions. In matters relating to mines the county is under the jurisdiction of the Duchy of Cornwall, of which the Heir Apparent is hereditary duke. The executory court of the duchy is called the Stannary court, its jurisdiction also including West Devon. The ancient county, which is in the diocese of Truro, contains 227 entire ecclesiastical parishes and parts of one other.

*Education.*—There is a residential training college for schoolmasters (Exeter Diocesan) at Truro. The number of elementary schools on 31st August 1899 was 339, of which 179 were board, and 160 voluntary schools, the latter including 136 National Church of England schools, 17 Wesleyan, 2 Roman Catholic, and 5 "British and other." The average attendance at board schools was 26,506, and at voluntary schools 18,517.

*Agriculture.*—Within recent years the area under cultivation has considerably increased, but it is still less than three-fourths of the total acreage. Of the cultivated area only about one-fifth is under corn crops, and nearly two-fifths under permanent pasture, in addition to which there are nearly 55,000 acres of hill pasture, over 31,000 acres under woods, and about 5000 acres under orchards. The acreage under wheat has greatly diminished, oats now occupying about one-half the total acreage under corn crops, and wheat and barley each about one-fourth. Nearly three-fourths of the acreage under green crops is occupied by turnips, swedes and mangold, and in addition cabbage occupies about one-fifth, while less than one-eighth is occupied by potatoes. The following table gives the main divisions of the cultivated area in 1880 and 1900:—

| Year. | Total Acreage under Cultivation. | Corn Crops. | Green Crops. | Clover. | Permanent Pasture. | Fallow. |
|---|---|---|---|---|---|---|
| 1880 | 551,221 | 137,297 | 56,399 | 154,566 | 182,633 | 20,329 |
| 1900 | 606,139 | 125,115 | 47,349 | 189,313 | 238,806 | 3,933 |

The principal live-stock in 1880 and 1899 were as follows:—

| Year. | Total Horses. | Total Cattle. | Cows or Heifers in Milk or in Calf. | Sheep. | Pigs. |
|---|---|---|---|---|---|
| 1880 | 31,527 | 163,604 | 55,145 | 426,550 | 60,193 |
| 1899 | 31,096 | 203,983 | 69,500 | 399,756 | 88,559 |

*Industries and Trade.*—According to the annual report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 10,923. The number of persons employed in mines and quarries in 1899 was 11,410. In 1899 the amount of igneous rocks raised was 222,614 tons valued at £97,008, and of slate 31,923 tons. The more valuable minerals in 1890 and 1899 were as follows:—

| Year. | Arsenic. | | China Clay. | | Copper. | | Tin. | |
|---|---|---|---|---|---|---|---|---|
| | Tons. | Value. | Tons. | Value. | Tons. | Value. | Tons. | Value. |
| 1890 | 3143 | £26,503 | 393,500 | £268,000 | 5271 | £15,301 | 14,867 | £780,017 |
| 1899 | 1361 | 13,295 | 506,228 | 290,620 | 5172 | 21,487 | 6,389 | 440,299 |

Large quantities of herring are obtained on the Cornwall coasts, along which there are numerous fishing stations. The valuable pilchard fisheries also retain their importance. The total quantity of fish landed at all stations in 1899 was over 400,000 cwts., valued at over £200,000; but much fish from Cornwall is landed at Plymouth in Devon.

**Cornwall,** the capital of the united counties of Stormont, Dundas, and Glengarry, Ontario, Canada, 65 miles south-west of Montreal, on the left bank of the river St Lawrence. It is an important station on the Grand Trunk and the Ottawa and New York Railways, and is a port of call for all steamers plying between Montreal and Lake

Ontario ports. The surplus water from the Cornwall Canal furnishes excellent water privileges for its large factories, which include cotton and woollen mills and grist and saw mills. Population (1881), 4468; (1901), 6500.

**Corot, Jean-Baptiste Camille** (1796–1875), French landscape painter, was born in Paris, in a house on the Quai by the Rue du Bac, now demolished, on 26th July 1796. His family were well-to-do bourgeois people, and whatever may have been the experience of some of his artistic colleagues, he never, throughout his life, felt the want of money. He was apprenticed to a draper, but hated commercial life and despised what he called its "business tricks," yet he faithfully remained in it until he was twenty-six, when his father at last consented to his adopting the profession of art. Corot visited Italy on three occasions: two of his Roman studies are now in the Louvre. He was a regular contributor to the Salon during his lifetime, and in 1846 was "decorated" with the knighthood of the Legion of Honour. He was promoted to be Officer in 1867. His many friends considered nevertheless that he was officially neglected, and in 1874, only a short time before his death, they presented him with a personal medal. He died in Paris in 1875 and was buried at Père Lachaise. Of the painters classed in the Barbizon School it is probable that Corot will live the longest, and will continue to occupy the highest position. His art is more individual than Rousseau's, whose works are more strictly traditional; more poetic than that of Daubigny, who is, however, Corot's greatest contemporary rival; and in every sense more beautiful than J. F. Millet, who thought more of stern truth than of æsthetic feeling.

Corot's works are somewhat arbitrarily divided into periods, but the point of division is never certain, as he often completed a picture years after it had been begun. In his first style he painted traditionally and "tight"—that is to say, with minute exactness, clear outlines, and with absolute definition of objects throughout. After his fiftieth year his methods changed to breadth of tone and an approach to poetic power, and about twenty years later, say from 1865 onwards, his manner of painting became full of "mystery" and poetry. In the last ten years of his work he became the Père Corot of the artistic circles of Paris, in which he was regarded with personal affection, and he was acknowledged as one of the five or six greatest landscape painters the world has ever seen, along with Hobbema, Claude, Turner, and Constable. During the last few years of his life he earned large sums by his pictures, which became greatly sought after. In 1871 he gave £2000 for the poor of Paris (where he remained during the siege), and his continued charity was long the subject of remark. Corot's works are spread over Europe and America. The Louvre possesses several important pictures by him, and there are examples in Lille, Bordeaux, Rouen, Rheims, Toulouse, and other centres. In England the "Macbeth" in the Wallace Collection is the only one in a public museum, but it is not characteristic of his best period; and in Scotland there is the splendid "Souvenir d'Italie" in the Glasgow Gallery. Besides landscapes, of which he painted several hundred, Corot produced a number of figure pictures which are now much prized. These were mostly studio pieces, executed, probably with a view to keep his hand in with severe drawing rather than with the intention of producing pictures. Yet many of them are fine in composition, and in all cases the colour is remarkable for its strength and purity. Corot also executed a few etchings and pencil sketches. In his landscape pictures Corot was more traditional in his method of work than is usually believed. If even his latest tree-painting and arrangement are compared with such a Claude as that which hangs in the Bridgewater Gallery, it will be observed how similar is Corot's method and also how masterly are his results.

The works of Corot are scattered over France and the Netherlands, Great Britain, and America, and it would be impossible except in a very extended list to name them. The following may be considered as the first half-dozen:—*Une Matinée* (1850), now in the Louvre; *Macbeth* (1859), in the Wallace Collection; *Le Lac* (1861); *L'Arbre Brisé* (1865); *Pastorale—Souvenir d'Italie* (1873), in the Glasgow Corporation Art Gallery; *Biblis* (1875). Corot had a number of followers who called themselves his pupils. The best known are Boudin, Lepine, Chintreuil, Français, and Le Roux.

(D. C. T.)

**Corpus Christi,** capital of Nueces county, Texas, U.S.A. It is a seaport, with a fine harbour, and is situated in the southern part of the state, on Corpus Christi Bay. Two railways, the Mexican National and the San Antonio and Aransas Pass, enter it. Population (1880), 3257; (1890), 4387; (1900), 4703.

**Correggio,** a town of Emilia, Italy (province Reggio), on a canal connecting the Secchia and the Po, 11 miles by rail north-east from Reggio. It has an old castle, and a fine monument (1880) to the painter Antonio Allegri, better known as Correggio, who was born here in 1494 and died here in 1534. Cheese and hats are manufactured. Population of commune (1881), 12,587; (1901), 14,437.

**Correnti, Cesare** (1815–1888), Italian revolutionist and politician, was born, 3rd June 1815, at Milan. While employed in the Public Debt administration he flooded Lombardy with revolutionary pamphlets designed to excite hatred against the Austrians, and in 1848 proposed the general abstention of the Milanese from smoking, which gave rise to the insurrection known as the Five Days. During the revolt he took part in the council of war and directed the operations of the insurgents. Until the fall of Milan he was Secretary-General of the Provisional Government, but after the restoration of Austrian rule he fled to Piedmont, whence he again distributed his revolutionary pamphlets throughout Lombardy. Elected deputy in 1849, he worked strenuously for the national cause, supporting the Crimea expedition and organizing a new revolt in Milan, which, however, was forestalled by the victory of Magenta. After the annexation of Lombardy he was made commissioner for the liquidation of the Lombardo-Venetian debt, and in 1860 was appointed Councillor of State. In 1867, and again in 1869, he held the portfolio of Public Instruction, taking considerable part in the events consequent upon the occupation of Rome, and helping to draft the Law of Guarantees. As Minister he suppressed the theological faculties in the Italian Universities, but eventually resigned office and allied himself with the Left on account of Conservative opposition to his reforms. His defection from the Right

"SKETCH OF A LANDSCAPE" BY COROT.

(*From an Engraving by M. Pastre.*)

ultimately assured the advent of the Left to power; and while declining office, he remained chief adviser of Depretis until the latter's death. On several occasions—notably in connexion with the redemption of the Italian railways, and of the Paris Exhibition of 1878—he acted as representative of the Government. In 1877 he was given by Depretis the lucrative sinecure of the Secretaryship of the Order of Saints Maurice and Lazarus, and in 1886 was created Senator. He died at Rome on 4th October 1888.

**Corrèze,** a department in the interior of France, traversed by the ramifications of the central plateau, and watered by the Dordogne, the Vezère, and the Corrèze.

Area, 2273 square miles, with 29 cantons and 287 communes. The population decreased from 326,494 in 1886 to 304,718 in 1901. Births in 1899, 7395, of which 299 illegitimate; deaths, 6263; marriages, 2451. In 1896 there were 761 schools, with 51,000 pupils, and 8 per cent. of the population was illiterate. The area under cultivation in 1896 amounted to 1,030,466 acres, 425,036 acres of which were plough-land, 276,767 acres natural pastures and grass lands, and 296,536 acres forests. The wheat return is low (£240,700), but in 1898 the rye crop yielded a value of £524,270, and the natural grass lands produced the value of £617,120. Chestnuts and walnuts are also an important crop, yielding in 1899 the value of £240,000. The live-stock amounted in 1899 to 990,200, of which 579,570 were sheep. There is not much working in metals, the department having but few mineral beds. Other industries are also little developed. Tulle, the capital, had a population of 17,000 in 1896.

**Corrientes,** a province of the Argentine Republic, south of Paraguay and west of the territory of Chaco. The official area at the census of 1895 was 32,579 square miles. The population in 1895 was 239,618. The province is divided into twenty-five departments. The capital, Corrientes, on the Paraná, 844 miles from Buenos Aires, had a population of 16,129 in 1895. In 1895 there were 13,632 farms and 136,119 acres planted in cereals, 424,483 head of horses, and 2,893,256 head of cattle.

**Corrigan, Michael Augustine** (1839–1902), third archbishop of the Roman Catholic archdiocese of New York, in the United States, was born in Newark, N.J., on 17th August 1839. In 1859 he began his studies for the priesthood as one of the twelve students with whom the American College at Rome was opened. On 19th September 1863, a year before the close of his theological studies, he was ordained priest, and in 1864 obtained the degree of D.D. Returning to America, he was appointed Professor of Dogmatic Theology and Sacred Scripture, and Director of the ecclesiastical seminary of Seton Hall College; soon after he was made vice-president of the institution; and in 1868, although hardly twenty-eight years of age, was appointed president of the college, one of the foremost of the Catholic educational institutions in the United States. When Archbishop Bayley was transferred to the see of Baltimore in 1873, Pius IX. appointed Father Corrigan bishop of Newark. In 1880 Bishop Corrigan was made coadjutor, with the right of succession, to Cardinal M'Closkey, archbishop of New York, under the title of Archbishop of Petra; and thereafter nearly all the practical work of the archdiocese fell to his hands. He was at the time the youngest archbishop in the Catholic Church in America. He died on 5th May 1902. On the death of Cardinal M'Closkey in 1885 Archbishop Corrigan became metropolitan of the diocese of New York.

**Corry,** a city of Erie county, Pennsylvania, U.S.A., situated in the north-western part of the state, on the Western New York and Pennsylvania, the Erie, and the Pennsylvania Railways, at an altitude of 1434 feet. It is within the limits of the great oil-fields of Western Pennsylvania and Southern New York, and it is to petroleum that it owes its existence and whatever measure of prosperity it enjoys. It was a place of much importance during the oil excitement between 1860 and 1870, and in the latter year had a population of 6809. As the excitement abated, however, its population diminished, so that in 1880 it numbered but 5277, in 1890 it was 5677, and in 1900, 5369.

**Corsica,** an island in the Mediterranean, forming a department of France; area, 3368 square miles, occupied by high mountains, and distributed among 62 cantons and 364 communes. The population in 1896 numbered 290,168, as compared with 278,501 in 1886. Births in 1899, 6947, of which 504 illegitimate; deaths, 5582; marriages, 1625. In 1896 the schools numbered 1170, with 46,000 pupils, and 15 per cent. of the population was illiterate. The total area under cultivation in 1896 amounted to 1,593,886 acres, of which 919,265 acres were arable land. In 1899 the wheat crop returned a value of only £57,800, while the produce of rye and oats together hardly exceeded £21,000; but the vine, which is making progress in the island, yielded a value of £278,000. In 1899 the crop of chestnuts was of the value of £154,000; oranges, £2820; citrons, £1640; cedrates, £22,000. The production of silkworm cocoons amounted in 1899 to 5813 cwt. The live-stock in 1899 included 10,730 horses, 9130 mules, 8730 asses, 157,990 cattle, 408,650 sheep, 74,300 pigs, and 215,920 goats. Corsica has no coal-pits, but some copper and lead mines, yielding 1100 metric tons in 1898, and some salt-pans, producing, in 1898, 520 metric tons of salt. The industries are in a backward state. The railway, of recent construction, goes from Bastia to Ajaccio, sending off a branch line to Calvi. The line had in 1899 a length of 182 miles.

**Corsicana,** capital of Navarro county, Texas, U.S.A., situated towards the north-eastern part of the state, at an altitude of 426 feet, on the Houston and Texas Central and the St Louis South-Western Railways. It is in a region largely devoted to the cultivation of cotton, for which staple it serves as a compressing- and shipping-point. Population (1880), 3373; (1890), 6285; (1900), 9313.

**Corti, Lodovico,** Count (1823–1888), Italian diplomatist, born at Gambarano 28th October 1823. Early involved with Cairoli in anti-Austrian conspiracies, he was exiled to Turin, where he entered the Foreign Office. After serving as artillery officer through the campaign of 1848, he was in 1850 appointed Secretary of Legation to London, whence, with the rank of Minister, he passed to Stockholm, Madrid, The Hague, Washington, and, in 1875, as Ambassador to Constantinople. Called by Cairoli to the direction of Foreign affairs in 1878, he took part both in the preliminary negotiations to the Congress of Berlin and in the Congress itself, but unwisely declined Lord Derby's offer for an Anglo-Italian agreement in defence of common interests. At Berlin he sustained the cause of Greek independence, but in all other respects remained isolated. While other Powers secured extensions of territory, he declined the German suggestion for an Italian occupation of Tunis, and excited the wrath of his countrymen by returning to Italy with "clean hands." For a time he withdrew from public life, but in 1881 was again sent to Constantinople by Cairoli, where he presided over the futile Conference of Ambassadors upon the Egyptian question. In 1886 he was transferred to the London Embassy, but was recalled by Crispi in the following year through a misunderstanding. He died at Rome on 9th April 1888.

**Cortland,** a village of New York, U.S.A., and capital of Cortland county, situated in the central part of the state, on Tioughnioga river, at the junction of its

east and west branches, at an altitude of 1122 feet. It has three railways, the Delaware, Lackawanna, and Western, the Erie and Central New York, and the Lehigh Valley. Population (1880), 4050; (1890), 8590; (1900), 9014.

**Cortona,** a town and episcopal see of Tuscany, Italy (province Arezzo), 30 miles north-west from Perugia by rail. The church of St Domenic, built about 1250, should be mentioned because of its fine paintings by Luca Signorelli, Fra Angelico, and others. Here is a technical school. Silk is manufactured. Population (1901), 29,343.

**Corunna,** a maritime province in the extreme north-west of Spain. The coast, which is very dangerous to navigation, is a succession of bays and estuaries, which are very picturesque, and often in close proximity to more rugged parts that are in reality the last spurs of the Cantabric chain. The province is very well watered by a great many small rivers and streams. Hills and mountain-sides are covered with forests and pastures. The climate is mild, with comparatively no extremes of cold or heat. The rains are quite as abundant as in the rest of Galicia, and even more so than in Asturias and the Basque provinces. It has an area of 3078 square miles, divided into 14 administrative districts and 97 parishes. The population was 596,436 in 1877, and 631,419 in 1897.

In very few provinces of the kingdom is the birth-rate so high, nor the proportion of illegitimates so great; the slow progress of the population, the death-rate being moderate, is attributed to the fact that emigration carries off on an average 3250 per annum. Education is in a backward condition, as in 1897, out of 129,976 children of both sexes, ranging from 4 to 14 years of age, only 46,603 were enrolled on the school registers, and only 29,487 ever attended the classes.

The railway lines actually open are only 45 miles. Other lines are being constructed. There were 63 unproductive mines in 1897, and 5 mines that were being worked. The latter were—1 arsenic pyrites, 2 iron, and 2 that showed traces of gold. The live-stock in 1897 included 25,565 horses, 3863 mules, 3250 asses, 104,147 sheep, 10,364 goats, 92,006 pigs, and 169,480 cattle. The rearing of cattle, formerly one of the most important industries of the province, has declined with the decrease of exportation, in particular to England; even to France and the interior of Spain it is not what it used to be. The yield of the principal crops in 1898 was—wheat, 2,087,395 bushels; rye, 1,091,086; beans, 54,596; chick peas, 1,177,650; maize, 2,190,444, the latter showing a falling off of over 2,500,000 bushels. Only about 1890 acres are covered with vines, that produce strongly alcoholic wine (491,392 gallons in 1898). The wheat crop covers 270,000 acres; rye, 170,000; maize, 70,000. As in the rest of Spain, the cultivation of beetroot has been started in the province for the sugar factories and to feed cattle. (A. E. H.)

**Corunna,** a seaport and the capital of the above province. The population was 37,240 in 1887, and 38,927 in 1897. The trade and commerce of Corunna depended so much on the Spanish colonies, especially Cuba and Porto Rico, that the loss of these seriously affected the exports and imports. The total value of the articles exported in 1898 amounted to £86,316 as against £185,061 in 1897, while the imports decreased to £205,602 from £352,323. The chief exports were flour, potatoes, beans, bacon and hams, tinned provisions, chocolate, wine, eggs; the imports were chiefly coals from England, and drugs, hides, metals, machinery, timber, cotton, maize, sugar, coffee, petroleum. The return of shipping during 1898 showed a total of 1157 vessels, and 983,121 aggregate tonnage. The harbour has been considerably improved. The new quay wall has been completed, and dredgers have been used successfully to deepen the anchorage. The depth of water is now 19 feet 6 inches at the quay walls at low tide, and powerful cranes have been erected on the wall to unload vessels. A lighthouse has been established at Cape Torinana. Corunna is the head of the railway line direct between Galicia and Madrid, and will soon be the terminus of lines in different directions in North-West Spain and Portugal.

**Corvey,** an abbey of Germany. See Hoxter.

**Cos,** or Kos (Italian, *Stanchio*; Turkish, *Istan-keui*, from ἐς τάν κῶ), an island separated from Cape Krio, near the south-west corner of Asia Minor, by a narrow strait. Under the name of Lungo it became part of the maritime state founded by the knights of Rhodes. In 1523, after the fall of Rhodes, it was annexed to the Osmanli Empire. The estimated population is 10,000: Moslems, 500; Greeks, 9500.

**Cosenz, Enrico** (1812–1898), Italian soldier, was born at Gaeta, 12th January 1812. As captain of artillery in the Neapolitan army he took part in the expedition sent by Ferdinand II. against the Austrians in 1848; but after the *Coup d'Etat* at Naples he followed General Pepe in disobeying Ferdinand's order for the withdrawal of the troops, and proceeded to Venice to aid in defending that city. As commandant of the fort of Marghera, Cosenz displayed distinguished valour, and after the fall of the fort assumed the defence of the Piazzale, where he was twice wounded. Upon the fall of Venice he fled to Piedmont, where he remained until, in 1859, he assumed the command of a Garibaldian regiment. In 1860 he conducted the third Garibaldian expedition to Sicily, defeated two Neapolitan brigades at Piale (August 23), and marched victoriously upon Naples, where he was appointed Minister of War, and took part in organizing the *plébiscite*. During the war of 1866 his division saw but little active service. After the war he repeatedly declined the portfolio of War. In 1881, however, he became chief of the general staff, and held that position until a short time before his death at Rome on 7th August 1898.

**Cosenza,** a town and episcopal see of Calabria, Italy, capital of the province Cosenza, 43 miles by rail south-south-west from Sibari, a junction on the railway along the east coast. It consists of the old town, with steep, narrow streets, and a better built new town, and is surrounded by villas of the provincial landowners. The town suffered severely from earthquakes in 1638, 1783, 1854, and 1870. Population (1881), 16,686; (1901), 21,420.

**Coshocton,** capital of Coshocton county, Ohio, U.S.A., on the Muskingum river, at the mouth of Tuscarawas river, and on the Ohio Canal. Three railways intersect at this place. Population (1890), 3672; (1900), 6473.

**Cosne,** chief town of arrondissement, department of Nièvre, France, 33 miles north-north-west of Nevers, on railway from Paris to Lyon. Its potteries are now important, and there is wool-spinning, and the preparation of phosphate is carried on in the vicinity; with commerce in wine, hemp, wood, iron, wool, and leather. Population (1881), 5241; (1891), 5737; (1901), 8580.

**Cossa, Pietro** (1830–1880), Italian dramatist, was born at Rome in 1830, and claimed descent from the family of Pope John XXIII., deposed by the council of Constance. He manifested an independent spirit

from his youth, and was expelled from a Jesuit school on the double charge of indocility and patriotism. After fighting for the Roman republic in 1849, he emigrated to South America, but failing to establish himself, returned to Italy, and lived precariously as a literary man until 1870, when his reputation was established by the unexpected success of his first acted tragedy, *Nero*. From this time to his death in 1880 Cossa continued to produce a play a year, usually upon some classical subject. *Cleopatra*, *Messalina*, *Julian*, enjoyed great popularity, and his dramas on subjects derived from Italian history, *Rienzi* and *The Borgias*, were also successful. *Plautus*, a comedy, was preferred by the author himself, and is more original. Cossa had neither the divination which would have enabled him to reconstruct the ancient world, nor the imagination which would have enabled him to idealize it. But he was an energetic writer, never tame or languid, and at the same time able to command the attention of an audience without recourse to melodramatic artifice; while his sonorous verse, if scarcely able to support the ordeal of the closet, is sufficiently near to poetry for the purposes of the stage. (R. G.)

**Cossacks** (Russian, *Kazak*; plural, *Kazaki*), the name given to considerable portions of the population of the Russian Empire, endowed with certain special privileges, and bound in return to give military service, all at a certain age, under special conditions. They constitute ten separate *Voiskos*, settled along the frontiers: Don, Kuban, Terek, Astrakhan, Ural, Orenburg, Siberian, Semiryechensk, Amur, and Usuri. The primary unit of this organization is the *stanitsa*, or village, which holds its land as a commune, and may allow persons who are not Cossacks (excepting Jews) to settle on this land for payment of a certain rent. The assembly of all householders in villages of less than 30 households, and of 30 elected men in villages having from 30 to 300 households (one from each 10 households in the more populous ones), constitutes the village assembly, similar to the *mir*, but having wider attributes, which assesses the taxes, divides the land, takes measures for the opening and support of schools, village grain-stores, communal cultivation, and so on, and elects its *ataman* (elder) and its judges, who settle all disputes up to £10 (or above that sum with the consent of both sides). Military service is obligatory for all men, for 20 years, beginning with the age of 18. The first 3 years are passed in the preliminary division, the next 12 in active service, and the last 5 years in the reserve. Every Cossack is bound to procure his own uniform, equipment, and horse (if mounted)—the Government supplying only the arms. Those on active service are divided into three equal parts according to age, and the first third only is in real service, while the two others stay at home, but are bound to march out as soon as an order is given. The officers are supplied in the usual way by the military schools, in which all Cossack *Voiskos* have their own vacancies, or are non-commissioned Cossack officers, with officers' grades. In return for this service the Cossacks have received from the State considerable grants of land, for each *Voisko* separately.

The total Cossack population in 1893 was 2,648,049 (1,331,470 women), and they owned nearly 146,500,000 acres of land, of which 105,000,000 acres were arable and 9,400,000 under forests. This land was recently divided between the *stanitsas*, at the rate of 81 acres per each soul, with special grants to officers (personal to some of them, *in lieu* of pensions), and leaving about one-third of the land as a reserve for the future. The income which the Cossack *Voiskos* receive from the lands which they rent to different persons, also from various sources (trade patents, rents of shops, fisheries, permits of gold-digging, &c.), as also from the subsidies they receive from the Government (about 712,500 l. in 1893), is used to cover all the expenses of State and local administration. They have besides a special reserve capital of about 2,600,000 l. The expenditure of the village administration is covered by village taxes. The general administration is kept separately for each *Voisko*, and differs with the different *Voiskos*. The central administration, at the Ministry of War, is composed of representatives of each *Voisko*, who discuss the proposals of all new laws affecting the Cossacks. In time of war the ten Cossack *Voiskos* are bound to supply 890 mounted *sotnias* or squadrons (of 125 men each), 108 infantry *sotnias* or companies (same number), and 236 guns, representing 4267 officers and 177,100 men, with 170,695 horses. In time of peace they keep 314 squadrons, 54 infantry *sotnias*, and 20 batteries containing 108 guns (2574 officers, 60,532 men, 50,054 horses). Altogether, the Cossacks have 328,705 men ready to take arms in case of need. As a rule, popular education amongst the Cossacks stands at a higher level than in the remainder of Russia. They have more schools and a greater proportion of their children go to school. In addition to agriculture, which (with the exception of the Usuri Cossacks) is sufficient to supply their needs and usually to leave a certain surplus, they carry on extensive cattle and horse breeding, vine culture in Caucasia, fishing on the Don, the Ural, and the Caspian, hunting, bee-culture, &c. The extraction of coal, gold, and other minerals which are found on their territories is mostly rented to strangers, who also own most factories.

The numerical forces and the territories of each *Voisko*, as also their war-footing, in 1894 (only slightly increased since) were as follows:—

| Voisko. | Territory—Acres. | Cossack Population. | War-Footing. |
|---|---|---|---|
| Amur, 1858 . . | c 2,750,000 | 19,700 | 6 squadrons, 3 companies infantry (33 off., 1529 men, 1070 horses). |
| Astrakhan . . | 2,080,000 | 26,627 | 13 squadrons (48 off., 2167 men, 2322 horses). |
| Don . . . . | 29,695,000 | 966,869 | 354 sq., 23 batt., 16 detachments (1627 off., 64,069 men, 65,793 horses, 140 guns). |
| Kuban . . . | 18,000,000 | 702,432 | 136 sq., 14 batt., 7 inf. detachm., 1 compy. militia (47,617 men, 37,895 horses, 30 guns). |
| Orenburg, 1755 . | 23,000,000 | 350,614 | 110 sq., 7 batt., 3 inf. det. (429 off., 20,639 men, 22,717 horses, 40 guns). |
| Semiryechensk, 1867 | c. 1,500,000 | 25,369 | 12 sq. (45 off., 1965 men, 2106 horses). |
| Siberian, xvii. c. (narrow strip from Orenburg to Irtysh and Bukhtarma; also in Kirghiz Steppe) | c. 15,000,000 | 113,546 | 54 sq. (189 off., 8901 men, 9477 horses). |
| Terek . . . | 5,400,000 | 162,156 | 70 sq., 2 inf. det., 2 batt. (342 off., 12,372 men, 13,543 horses, 12 guns). |
| Transbaikalia, 1822, 1851 | c. 8,150,000 | 181,474 | 18 sq., 30 compy., 3 batt. (231 off., 9319 men, 4050 horses, 12 guns). |
| Ural . . . . | c. 17,500,000 | 110,986 | 38 sq., 2 inf. det. (198 off., 8724 men, 9229 horses). |
| Usuri, 1858 . . | Undetermined | 7,040 | 5 sq. (12 off., 583 men, 624 horses). |
| Total, . . . | Over 120,000,000 | 2,666,813 | 816 sq., 70 inf. coy. and inf. det., 49 batt. (3157 off., 177,885 men, 236 guns). |

A military organization similar to that of the Cossacks has lately been introduced into certain districts, which supply a number of mounted infantry *sotnias*. Their peace-footing is as follows:—Daghestan, 6 regular squadrons and 3 of militia; Kuban Circassians, 1 *sotnia*; Terek, 8 *sotnias*; Kars, 3 *sotnias*; Batum, 2 infantry and 1 mounted *sotnia*; Turkomanes, 3 *sotnias*; total, 25 squadrons and 2 companies.

(P. A. K.)

**Costa, Sir Michael** (properly **Michele**) (1810–1884), musical conductor and composer, son of Cav. Pasquale Costa, a Spaniard, was born at Naples, on 4th February 1810. He early became a free scholar of the Royal Music School at Naples, and at sixteen he wrote his first opera, *Il Delitto punito*, at seventeen *Il Sospetto funesto*, a mass, and an oratorio. In 1828–29 he further composed *Il Carcere d'Ildegonda* and *Malvina* for the Teatro Nuovo and San Carlo, and in this latter year he visited Birmingham to conduct Zingarelli's "Cantata Sacra," a setting of some verses from the book of Isaiah. Instead, however, of conducting, he sang the tenor part. From that time he settled in England, and became naturalized, receiving the honour of knighthood in 1869. He conducted the opera at Her Majesty's from 1832 till 1846, when he seceded to the Italian Opera at Covent Garden; he was conductor of the Philharmonic Society from 1846 to 1854, of the Sacred Harmonic Society from 1848, and of the Birmingham Festival from 1849. In 1855 Costa wrote *Eli*, and in 1864 *Naaman*, both for Birmingham. Meanwhile he had conducted the Bradford (1853) and Handel Festivals (1857–1880), and the Leeds Festivals from 1874 to 1880. On 28th April 1884, he died at Brighton. Costa's compositions have passed into oblivion, with the exception of the least admirable of them—his arrangement of the National Anthem. He was a man of restricted musical and human sympathies (witness his animosity against Sterndale Bennett); but he was a great conductor within well-defined limits.

(R. H. L.)

**Costa Rica,** a country of Central America, lying between 8° and 11° 16′ N. lat. and 80° 35′ and 85° 40′ W. long. The boundary dispute with Nicaragua, alluded to in the 9th edition article, was referred to the arbitration of the President of the United States, who, by his award in 1888, gave the whole of Lake Nicaragua and the upper waters of the San Juan river to Nicaragua, and the lower San Juan, down to the Atlantic and the Bay of Salinas, on the Pacific, to Costa Rica. Disputes respecting the demarcation of this boundary have been settled under treaty of 1896, and the delimitation is now nearly complete. The line of frontier towards Colombia was referred for arbitration to the President of the French Republic, who gave his award on 15th September 1900. The boundary begins at Cape Mona on the Atlantic, and, generally following lines of watershed, touches the Pacific at Burica Point (see COLOMBIA).

The climate of Costa Rica is tempered by the proximity of the country to two great oceans, the average temperature at Jan José being about 68° F. The hottest months are usually May and June, and the coldest usually January, but, according to observations extending over the year 1896 at Jan José, the maximum of 90° F. was reached in March, and the minimum of 50° F. in February. The rainfall at San José from May to November averages about 12 inches a month, and during the year from 70 to 80 inches. Port Limon is said to have an annual rainfall of 89 inches, and Colon 120 inches.

*Area and Population.*—According to the most recent official estimate, Costa Rica has an area of 23,000 square miles; but, according to planimetric calculations at Gotha, the area is 20,900 square miles. The population in 1892, according to the census, numbered 243,205, of whom 122,480 were male and 120,725 female. Allowance being made for probable omissions, the total number of inhabitants was 262,700, or about 11 to the square mile. The population in 1899 was estimated at 310,000. The census population in 1892 was distributed over the five provinces and two comarcas (or territories) as follows:—San José, 76,718; Alajuela, 57,203; Cartago, 37,973; Heredia, 31,611; Guanacaste, 20,049; Puntarenas (comarca), 12,167; Limon (comarca), 7484. The predominant element in the population consists of whites, many of them of pure blood, descended from Galician Spaniards. They live mostly in the capital and other towns in the highlands, and in the commercial ports. The coast regions are occupied by negroes and a mixed population, while in the interior there are uncivilized Indians, estimated at about 3500, living by themselves. The foreign population at the date of the census numbered 6289, of whom 831 were Spanish, 622 Italian, 342 German, 246 British, and 204 from the United States. There were also 634 British subjects (coloured) from the West Indies. The total births recorded in 1897 numbered 13,012; deaths, 9925; marriages, 1763. The principal towns are San José, the capital of the Republic, with about 25,000 inhabitants, and the provincial capitals of like names with the provinces. Limon, the principal port, has about 4000 inhabitants.

*Constitution.*—According to the Constitution, which received its most recent modification in 1882, the legislative power resides in a Congress of one house, consisting of deputies (1 for every 8000 of population), chosen for four years, half the number retiring every two years. They are chosen in electoral assemblies returned by the votes of all citizens who are able to support themselves. The President is similarly elected, and holds office for four years. For the administration of justice there are a Supreme Court and subordinate tribunals.

*Religion and Education.*—In 1892 the Protestants numbered 2245. The Jesuits were expelled in 1884. Elementary education is compulsory, and is provided at the cost of the Government. In 1898 there were 383 primary schools with 917 teachers and 23,134 enrolled pupils. Higher education is given in a *liceo* with 206 students, a college for ladies with 223 students, and three other institutions. There are also schools of medicine and of law. The Government encourages higher education by maintaining ten Costa Rican youths at European universities, and steps are being taken towards the formation of a National University. The expenditure of Government on public instruction in the year 1899–1900 amounted to 679,843 pesos (£54,387).

*Defence.*—All citizens from 18 to 50 years of age are liable to military service. Those under 40 are comprised in the "active service," the remainder in the "reserve." The national guard consists of all citizens outside of these age limits, but capable of bearing arms. On war footing, the military force would exceed 34,000 men. The Republic has a gunboat and a torpedo boat.

*Finance.*—Of the revenue of Costa Rica about 47 per cent. is derived from customs, 25 per cent. from spirit monopoly, 8 per cent. from the tobacco tax, and smaller proportions from stamps, the post office, railways, and other sources. The most important spending departments are those of Internal Development, Instruction, and Government. Outside of these, large amounts are devoted to the national debt. The revenue and expenditure for six years ending March 31 (at $12\frac{1}{2}$ pesos = £1) were:—

| Years. | Revenue. | Expenditure. | Years. | Revenue. | Expenditure. |
|---|---|---|---|---|---|
| 1895 | £489,910 | £489,720 | 1898 | £673,930 | £665,080 |
| 1896 | 502,320 | 495,030 | 1899 | 673,060 | 644,850 |
| 1897 | 594,850 | 535,790 | 1900 | 658,010 | 595,600 |

The external debt, according to arrangements made in 1885 and 1897, consists of a New Consolidated Debt of £2,000,000, at $2\frac{1}{2}$ and 3 per cent.; but there are now, in addition, arrears of interest amounting to £85,000. The service of this debt costs about £58,200 annually. The internal debt amounts to about 1,116,800 pesos, or about £89,340, and costs 252,127 pesos, or £20,170 annually.

*Production and Industry.*—The principal industries are agricultural. To a large extent the soil is owned and occupied by small landowners, industrious and peaceable, who form the backbone of the population. In the interior coffee-growing is prosperous, the produce being of excellent quality and commanding a high price in the market. The annual yield has increased from 20,216,000 lb in 1883 to 25,172,400 lb in 1893, 30,040,900 lb in 1897, 42,869,500 lb in 1898, 33,806,680 lb in 1899. Next to coffee the most important culture is that of bananas, which are grown on the Atlantic coast region, the crop in 1898 amounting to 2,962,770 bunches, and in 1899 to 3,594,700. Sugar, tobacco (formerly a Government monopoly), rice, beans, potatoes, and other crops are grown for local consumption, and there are some cocoa plantations. In the forests the natural timber and dye-woods are cut, and rubber

is collected for exportation. The working of the gold and silver mines has been largely discontinued. The minor industries within the Republic comprise a foundry and national workshop, at San José, where machinery, farming implements, tools, &c., are manufactured, and a silk and cotton factory, and a few other establishments. The live-stock in 1892 consisted of 345,665 cattle, 77,043 horses, 2765 sheep, and 62,328 swine.

*Commerce.*—The imports into Costa Rica are mainly textiles, provisions, iron goods, and live animals; while coffee, bananas, wood hides, and (recently) rubber are exported. The following have been the values of the imports and exports (the gold peso being taken at 4s.):—

| Years. | Imports. | Exports. |
|---|---|---|
| 1896 . . | £950,000 | £1,120,000 |
| 1897 . . | 1,092,000 | 1,095,000 |
| 1898 . . | 906,000 | 1,132,000 |
| 1899 . . | 827,000 | 986,000 |

In 1899 the coffee exports amounted to the value of £593,000; bananas, £236,000; timber and dye-woods, £68,000; hides, £21,000; rubber, £21,000. Of the imports in the same year, 54 per cent. in value were from the United States, 20 per cent. from Great Britain, 15 per cent. from Germany; of the exports of coffee, 55 per cent. went to Great Britain, 26 per cent. to the United States, and 15 per cent. to Germany. All the banana exports were to the United States.

*Shipping and Communications.*—The trade of the Republic passes through the ports of Limon on the Atlantic, and Puntarenas on the Pacific. Limon is visited monthly by 26 steamers providing communication with Europe, the United States, and the West Indies, while from 8 to 10 steamers plying on the Pacific coast call monthly at Puntarenas. In 1898, 449 vessels entered the two ports. In some districts within the Republic there are fairly good cart roads maintained by the Government, which in the year 1896–97 spent more than £15,500 on roads and bridges. The railway from Limon to San José and Alajuela, belonging partly to the Government but mainly to an English company, has, with its branches, a length of 138 miles, and carried in 1898, 601,198 passengers and 160,000 tons of goods. The Pacific railway from San José to Tivives, which is being constructed for the Government, is completed to the length of 12 miles and partially constructed for 40 miles, 19 miles being not yet begun. Within the Republic there are 83 post offices, through which, in 1898, 4,226,000 pieces of mail passed. The telegraph line in 1897 had a length of 917 miles, and was served by 43 telegraph offices. About 203 miles of telephone wire connect San José with other localities. The nearest telegraph cable station is at San Juan del Sur, on the Pacific in Nicaragua.

*Money and Credit.*—Within the Republic there are 2 important banks, the Anglo-Costa Rican Bank and the Bank of Costa Rica, with capital of 1,200,000 and 2,000,000 pesos respectively. On April 25, 1900, a new law was enacted for the regulation of the constitution, capital, note emission, and metallic reserves of banks. On October 24, 1896, an Act was passed for the adoption of a gold coinage, and the execution of this Act was decreed on April 17, 1900. The monetary unit is the gold colon weighing ·778 grammes, ·900 fine, and thus worth about 23d. It will be legally equivalent to the silver peso, which will continue in circulation. The metallic currency, as stated in the President's message, consists of 5,000,000 gold colons and 1,000,000 in silver money, while the circulating notes of the Bank of Costa Rica, exchangeable for gold, amount to 3,000,000 colons. The gold coins of the United States, Great Britain, France, and Germany are legally current.

The metric system of weights and measures was introduced by law in 1884, but the old Spanish system is still in use.

(W. W. R.; C. E. A.)

**Côte-d'Or,** a department in the east of France, traversed by the hills of Côte-d'Or, and divided between the basins of the Seine and of the Saône.

Area, 3392 square miles. The population, 381,574 in 1886, numbered only 361,626 in 1901. Births in 1899, 6362, of which 524 were illegitimate; deaths, 7279; marriages, 2389. Dijon, the capital, had in 1896 67,000 inhabitants. In 1896 the schools numbered 1170, with 52,000 pupils, and 1 per cent. of the population was illiterate. Agriculture forms the principal wealth of Côte d'Or. The area under cultivation in 1896 comprised 2,001,625 acres, 1,057,628 acres of which were plough-land and 59,306 acres vineyards. The wheat produce in 1898 amounted to the value of £1,847,000; rye, £86,520; barley, £197,920; oats, £700,300. Potatoes returned a value of £446,795, and mangold-wurzel £173,500. The grass lands of all kinds, including the lands growing trefoil, lucern, and sainfoin, yielded the value of £809,000, while the produce of beetroot amounted to the value of £38,500. The vineyards returned a value in 1898 of £1,385,200. The livestock in 1899 included 47,200 horses, 157,420 cattle, 288,480 sheep, and 63,810 pigs. The department mines a small quantity of coal, and much limestone and marble. The metallurgy registered in 1898 4800 metric tons of iron and 11,300 tons of steel, which, with the other industries, amounted to the value of £137,000. The distillation of alcohol in 1898 amounted to 352,000 gallons.

**Côte-du-Nord,** a department in the west of France, bordering on the English Channel.

Area, 2787 square miles, with 48 cantons and 390 communes. The population decreased from 628,256 in 1886 to 609,349 in 1901. Births in 1899, 16,780, of which 642 were illegitimate; deaths, 13,571; marriages, 4527. There were, in 1896, 982 schools, with 95,000 pupils. The illiterate, who are strongly represented in this department, amounted to between 9 and 10 per cent. St Brieuc, the capital, had in 1896 a population of 21,000; the sub-prefectures are Dinan, Guingamp, Lannion, and Loudéac. The total area under cultivation in 1896 comprised 1,386,311 acres, of which 1,109,542 acres were plough-land. The vine has no place in the statistical returns. The wheat crop yielded in 1899 the value of £1,183,000; rye, £211,000; barley, £183,000; buckwheat, £315,400; oats, £713,800. The potato crop of 1899 was of the value of £613,000, and the natural pastures gave a return of £908,000. Côtes-du-Nord produced flax to the value, including both harl and seed, of £73,000, thus taking the first rank in 1899 among the departments of France in the culture of flax. Cider-apples in 1899 produced 206,126 cwts. of the value of £50,000. The live-stock comprised 92,800 horses, 317,000 cattle, 76,300 sheep, and 148,300 pigs. The department is famed for its horses. The value of milk products in 1899 was £2,040,000. The mining industry produced in 1898 613 metric tons of iron, and the working in metals 8700, of the value of a little less than £30,000.

**Cotrone,** a fortified town and seaport and bishop's see of Calabria, Italy (province Catanzaro), on the east coast, 148 miles north-east from Reggio by rail. There is a small but good harbour, protected by two moles, with a coasting trade (360 vessels of 74,319 tons cleared in 1897) in wine, olive oil, fruits, and liquorice. Population (1881), 7689; (1900), 9610.

**Cottbus,** or KOTTBUS, a town of Prussia, on the Spree, 72 miles south-south-east of Berlin by rail. It has four Protestant churches, a Catholic church, and a synagogue, a gymnasium, a higher grade, a technical, and other special schools. Population (1890), 34,900; (1900), 39,327.

**Cotton Printing.**—Recent progress in cotton printing has been mainly in the direction of expedition. This applies to printed cretonne, chintz, velvet, linen, or whatever the fabric which has in turn come into fashion. To a great extent machine printing has taken the place of hand work; the readier process of "steaming," as it is called, has been adopted in place of first printing in mordants and then dyeing; and the natural vegetable dyes have been superseded by artificial products of the

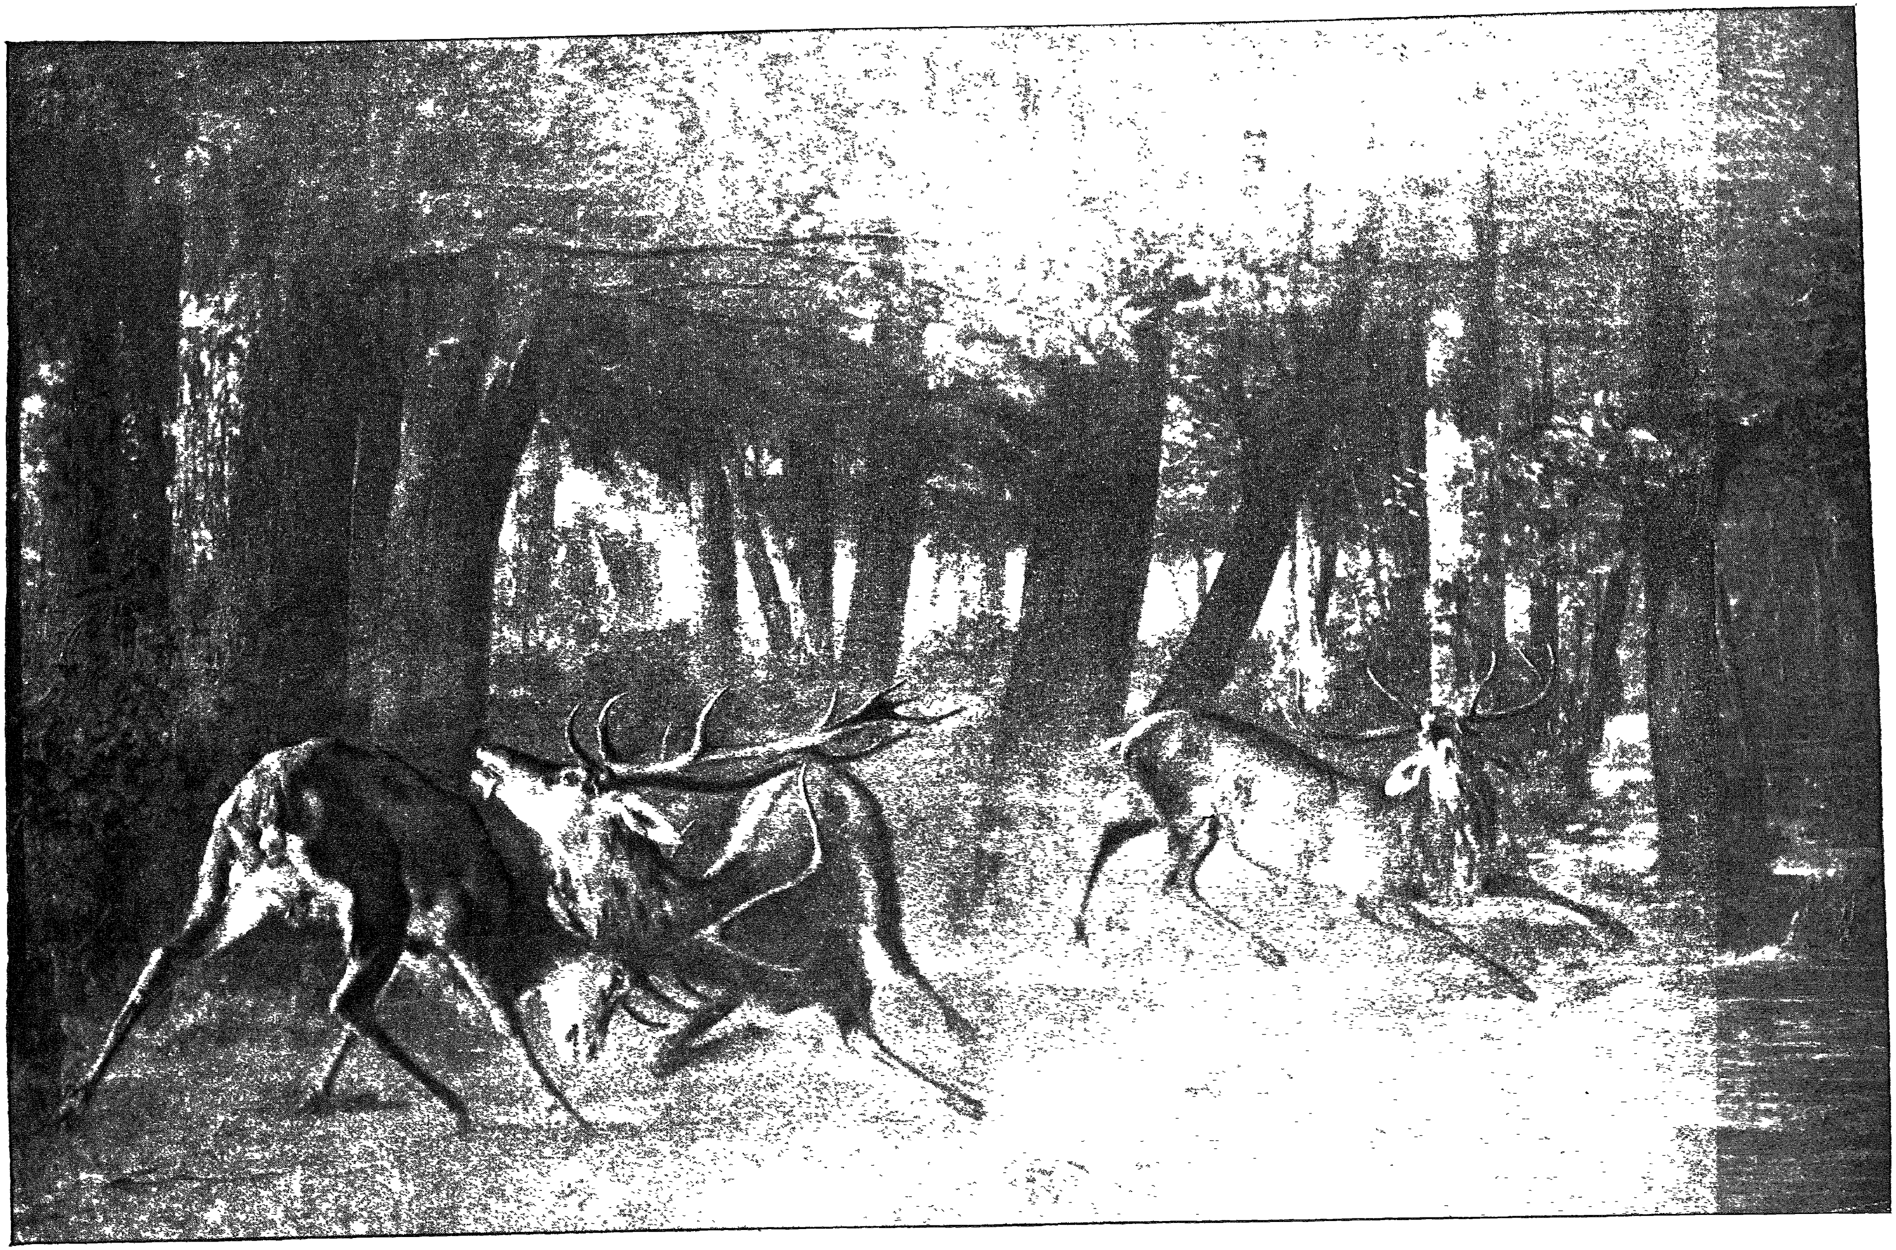
laboratory. From the point of view of commerce this is all to the good. From the artistic standpoint it is not so. It led, indeed, to a condition of things which went far to justify the contention that all this "improvement" amounted in effect to the degradation of handicraft to the level of trade. When it was boasted by the manufacturer that a machine printed with more precision than a hand block, the artist pointed out that the result was mechanical; when it was claimed that the "steaming" process was cheap, it was answered that it was proportionately nasty; when it was urged that aniline gave brighter colours than vegetable dyes, it was complained that they were crude. And there was truth in these retorts: the precision of machine printing is not altogether an artistic gain; the rough and ready process of mixing dye and mordant into one printing paste, and allowing them, as it were, to fight it out between them in the steam-box, does not result in the purest of prints; and the possibility of getting out of coal-tar unmitigated shades of colour led to the shocking abuse of garish greens, purples, &c. Moreover, the method (at first adopted) of attaching the pigments to the cloth by means of albumen did not make them fast; and, in fading, they did not simply mellow or sadden like the fugitive tints of old tapestry, but grew sickly, and passed through various unwholesome shades of difference to decay. All this naturally aroused artistic animosity, and there was something like a crusade against artificial dyestuffs. William Morris, who was at the head of this movement, went further than mere protest against the new methods, and himself set to work at printing according to the old, and more or less obsolete, practice; and his cottons found ready acceptance at the hands of artists and others better qualified to admire the beauty and originality of his design than to form any just opinion as to the relative value of the method of dyeing it pleased him to adopt. They took it too readily for granted that all pleasant colour was produced from vegetable dyes, and that all artificial dyes, therefore, were ugly.

The truth is that the ancient art of dyeing with vegetable stains had in the course of ages been perfected. The more fugitive and otherwise untrustworthy substances had been found out, the really serviceable had been tested, and a dyer knew what he had to depend upon, and for what he could depend upon it. On the other hand, when new dyestuffs came everyday to be produced in the laboratory, all use of them was experimental; and it is only after many failures that satisfactory results begin to be achieved. The failures in aniline dyeing were obvious. Arsenite of alumina proved a more efficient fixative than albumen, but was open to the objection of the poisonous nature of arsenic—an objection not applicable to tannic acid, which is now mixed with the colour, and when treated (after steaming) with tartrate of antimony forms a quite insoluble dye. With the introduction of alizarine and of what is known as the "direct" series of colours (which have such affinity with cotton as to require no mordant), printing in artificial dyestuffs entered upon a stage of success already marked enough to show that the falling back upon old-world methods was a counsel of despair, not warranted by the actual condition of things. An artist's sympathy with his material leads him, rightly, to work on the lines determined by it; and the palette offered by vegetable dyes is in a sense sufficient for him; but dye printing is not simply an art: it is an industry, supported by folks who neither know nor care about the limitations of vegetable tinctures; and, now that chemistry comes with its promise of so much wider scope in colour, it would show little enterprise on the part of the printer were he content to accept limitations no longer binding on him. As a matter of fact, the ideal of a range of colours, practically unlimited, all from one base, all to be printed at one operation, all to be developed and fixed by one process, seems on the way to no very distant realization. The last word of science is to the effect that alizarine colours are more permanent than vegetable dyes. At the very end of the 19th century these have produced artificially an indigo practically indistinguishable from the natural product. It does not, however, appear that modern methods can ever do quite what was done by the old. By the leisurely process of block-printing, in vegetable dyes, the printer gets a purity of delicate tint not as yet approached by rapid roller-printing in artificial dyestuffs—and there are obvious reasons, mechanical and chemical, why this should be so. To get the old effects it is necessary (and perhaps always will be) to adopt the old methods. But these effects are not the only ones that are beautiful. And, though they are proper to the old way of printing, there are other effects, beautiful also, quite as proper to the new. It is these which the astute printer seeks, knowing that so long as he aims at what has been done, and better done than his means allow, he puts himself at a disadvantage. The artistic development of cotton printing on the scale of a great industry must depend upon a full appreciation of what new and scientific methods can and cannot do, and upon the production of designs not only conceived in the spirit of art but schemed with the practical purpose of making much of the capacities of the industry under the conditions, commercial and other, which it is bound to obey. Probably the most considerable development of dye-printing in recent years has been in the extended use of "discharge"—dyeing rich grounds, discharging the pattern, and printing it in colours—all but impossible to the printer except in collaboration with the designer. Considerable improvement in the design of cotton prints has followed upon the revived interest in applied art characteristic of the latter part of the 19th century; even up-to-date extravagance may pass for evidence of vitality; but the aim is more often mere novelty than beauty. Moreover, too great a readiness on the part of the printer to meet demands made in ignorance of the conditions governing good work has led of late years to a departure from the ways of technique, which are indeed also the ways of art in so far as art is possible in cotton printing. (L. F. D.)

**Cotton,** and **Cotton-seed.** See AGRICULTURE (*United States*).

**Couillet,** a town of Belgium, in the province of Hainaut, 24 miles south-south-east of Mons, with a station on the railway between Charleroi and Namur. It has forges and furnaces and important ironworks. Population (1880), 7142; (1897), 9339.

**Council Bluffs,** capital of Pottawattamie county, Iowa, U.S.A., situated in 41° 16′ N. lat. and 95° 51′ W. long., in the western part of the state, in the bottom land at the foot of the bluffs, on the east side of Missouri river, at an altitude of nearly 1000 feet. It is the second largest and most important city of western Iowa, and a railway centre of the first importance, being the converging-point of five great systems from the east. These are the Chicago, Burlington, and Quincy, the Chicago, Milwaukee, and St Paul, the Chicago, Rock Island, and Pacific, the Illinois Central, and the Chicago and North-Western; while the Union Pacific comes from the west. The point of junction of these lines is at Transfer Station, just outside the city, on the bank of the Missouri. It is connected with Omaha, on the opposite bank of the river, by two iron bridges and by steam and electric cars. It is a railway,



"The Stag Fight." By Courbet.

*(From a Photograph by Neurdein.)*

rather than a manufacturing, city. In 1890 its capital invested in manufactures was $1,292,283, and the value of its products was $2,527,388. Population (1880), 18,063; (1900), 25,802, including 240 negroes.

**Coupon,** a certificate entitling its owner to some payment, share, or other benefit; more specifically, one of a series of interest certificates or dividend warrants attached to a bond running for a number of years. The word coupon (a piece cut off) possesses an etymological meaning so comprehensive that, while on the Stock Exchange it is only used to denote such an interest certificate or a certificate of stock of a joint-stock company, it may be as suitably, and elsewhere is perhaps more frequently, applied to tickets sold by tourist agencies and others. The coupons by means of which the interest on a bond or debenture is collected are generally printed at the side or foot of that document, to be cut off and presented for payment at the bank or agency named on them as they become due. They pass by delivery, and are as a rule exempt from stamp duty. Coupons for the payment of dividends are also attached to the share warrants to bearer issued by some joint-stock companies. The coupons on the bonds of most of the principal foreign loans are payable in London in sterling as well as abroad. (S. D. H.)

**Courbet, Gustave** (1819–1877), French painter, was born at Ornans (Doubs) on the 10th June 1819. He went to Paris in 1839, and worked at the studio of Steuben and Hesse; but his independent spirit did not allow him to remain there long, as he preferred to work out his own way by the study of Spanish, Flemish, and French painters. His first works, an "Odalisque," suggested by Victor Hugo, and a "Lélia," illustrating George Sand, were literary subjects; but these he soon abandoned for the study of real life. Among other works he painted his own portrait with his dog, and "The Man with a Pipe," both of which were rejected by the jury of the Salon; but the younger school of critics, the neo-romantics and realists, loudly sang the praises of Courbet, who by 1849 began to be famous, producing such pictures as "After Dinner at Ornans" and "The Valley of the Loire." The Salon of 1850 found him triumphant with the "Burial at Ornans," the "Stone-Breakers," and the "Peasants of Flazey." His style still gained in individuality, as in "Village Damsels" (1852), the "Wrestlers," "Bathers," and "A Girl Spinning" (1852). Though Courbet's realistic work is not devoid of importance, it is as a landscape and sea painter that he will be most honoured by posterity. Sometimes, it must be owned, his realism is rather coarse and brutal, but when he paints the forests of Franche-Comté, the "Stag-Fight," "The Wave," or the "Haunt of the Does," he is inimitable. When Courbet had made a name as an artist he grew ambitious of other glory; he tried to promote democratic and social science, and under the Empire he wrote essays and dissertations. His refusal of the Cross of the Legion of Honour, offered to him by Napoleon III., made him immensely popular, and in 1871 he was elected, under the Commune, to the Chamber. Thus it happened that he was responsible for the destruction of the Vendôme column. A council of war, before which he was tried, condemned him to pay the cost of restoring the column, 300,000 francs (£1200). To escape the necessity of working to the end of his days at the orders of the State in order to pay this sum, Courbet went to Switzerland in 1873, and died at La Tour du Peilz, 31st December 1877, of a disease of the liver aggravated by intemperance. An exhibition of his works was held in 1882 at the École des Beaux-Arts.

See CHAMPFLEURY. *Les grandes figures d'hier et d'aujourd'hui.* Paris, 1861.—MANTZ. "G. Courbet," *Gaz. des Beaux-Arts.* Paris, 1878.—ZOLA. *Mes Haines.* Paris, 1879.—C. LEMONNIER. *Les Peintres de la Vie.* Paris, 1888. (H. FR.)

**Courbevoie,** a town in the arrondissement of St Denis, department of Seine, France, 5 miles west-north-west of Paris, on railway to Versailles. It is a residential suburb of Paris, and has a fine avenue opening on the Neuilly Bridge, and forming with it a continuation of the Champs Elysées. It has manufactures of waggons and awnings. Port traffic, 1899, amounted to 88,074 tons. Population (1881), 13,094; (1901), 25,330.

**Courcelles,** a town of Belgium, in the province of Hainaut, 21 miles east of Mons by rail. It has a coal-mining industry, and manufactures linen and articles of iron. Population (1880), 11,190; (1890), 12,654; (1897), 14,494.

**Courland,** one of the Baltic provinces of Russia, bounded by the Baltic on the W., the Gulf of Riga and the Western Düna (Livonia and Vitebsk) on the N.E., and Kovno on the S. The Mitau Plain divides it into two parts, of which the western is fertile and thickly inhabited, excepting in the north, where there is another patch of lowlands, while the eastern is much less so. It is undulating elsewhere, and covered with spurs of the plateau of Lithuania, a hilly and picturesque tract of land which separates the Düna from the Aa, and is known as Upper Courland. Another range of heights stretches along the Windau. Neither exceeds 600 feet in altitude. The province consists mainly of Devonian rocks, besides Jurassic as far as Windau, both thickly covered with glacial deposits. Large parts are occupied by marshes, often clothed with forests, and they are sandy tracts and downs on the seashore. The marshes are drained, and the sands covered with plantations of trees. Nearly one-third of the surface is still forest, watered by nearly a hundred rivers, of which only the Düna, the Aa below Mitau, and the Windau are navigable. They all flow north-westwards and enter the Baltic Sea. The sea-coast is poor in harbours, and the only ports are Libau, Windau, and Polangen, there being none on the Courland coast of the Gulf of Riga. Population (1897), 672,634 (345,756 women), of whom, according to Rittich, 8 per cent. only are Germans, the remainder being Letts (49 per cent.), Coures (30 per cent.), Jews (6 per cent.), Russians (2 per cent.), Poles, Lithuanians, and Lives. Urban population, 148,134.

The land laws in the Baltic provinces being different from those of Russia, the land is mostly in private ownership, and 2,616,740 acres belong to 535 landlords, mostly nobles, two-fifths of whom own estates of more than 2700 acres each; 2,356,800 acres are owned or held by the peasants; and 1,354,560 acres belong to the Crown. In 1863 special laws were issued in order to enable the Letts to acquire the farms which they held, and special banks were founded. With their aid nearly 12,000 farms were bought by the peasants settled on landlords' estates, but it is estimated that nearly 300,000 Letts remain landless, and are hired labourers (*knechts*) on the farms and estates, occupying a very low position in the social scale. Agriculture reaches a high degree of perfection on the landlords' estates, and although the wet climate of Courland prevents droughts, artificial irrigation from artesian wells (about 200) is resorted to. 1,660,000 acres are arable land, of these 918,000 being under corn crops, 351,000 under flax, 67,500 under potatoes; and 2,078,000 under meadows and pasturages. Cattle-breeding is on a small scale, but excellent breeds of horned cattle, sheep, and swine are kept; also 141,100 horses. The factories numbered 315 in 1893, employing 6000 persons, and yielding returns of about £1,300,000, Libau and Mitau being the main industrial centres. There are also ironworks, agricultural machinery, tanneries, glass and soap works. Flax spinning is yet in the stage of a domestic industry. Navigation on the Düna and Aa is important for export, and still more the traffic on the railways which lead from Central Russia to Riga and Libau, the latter being one of the chief Russian ports. The Government is well provided with schools, and education is obligatory. The chief towns of the ten districts are:—Mitau

(Doblenskiy district), capital of the Government (35,011 inh.); Bauske (6543); Friedrichstadt (6800); Goldingen (9733); Grobin (1489); Hasenpoth (3338); Illuxt (2340); Talsen (1485); Tuckum (7542); Windau (7132). (P. A. K.)

**Courtney, Leonard Henry** (1832——), English politician and man of letters, eldest son of Mr T. S. Courtney, a banker at Penzance, was born at Penzance on 6th July 1832. At Cambridge he was Second Wrangler and First Smith's Prizeman, and was elected a Fellow of his College, St John's. He was called to the Bar at Lincoln's Inn in 1858, was Professor of Political Economy at University College from 1872 to 1875, and in December 1876, after a previous unsuccessful attempt, was elected to Parliament for Liskeard in the Liberal interest. He continued to represent the borough, and the district into which it was merged by the Reform Act of 1885, until 1900, when his differences with the majority of his constituents on the South African question —on which he was one of the foremost of the so-called "Pro-Boer" party—compelled his retirement. Until 1885 he was a devoted adherent of Mr Gladstone, particularly in finance and foreign affairs. In 1880 he was Under Secretary of State for the Home Department, in 1881 for the Colonies, and in 1882 Secretary to the Treasury; but Mr Courtney has always been a stubborn fighter for principle, and upon finding that the Government's Reform Bill in 1884 contained no recognition of the scheme for proportional representation, to which he was deeply committed, he resigned office. Mr Courtney manifested the same fidelity to his convictions by refusing to support Mr Gladstone's Home Rule Bill in 1885, and was one of those Liberal Unionists who chiefly contributed to its rejection, and whose reputation for unbending integrity and intellectual eminence gave solidity to the section of Liberals who followed Lord Hartington. In 1886 Mr Courtney was elected Chairman of Committees in the House of Commons, and his efficiency in this arduous office seemed to many to mark him out for the Speakership when a vacancy occurred in 1895. A Liberal Unionist, however, could only be elected by Conservative votes, and he had made himself objectionable to a large section of the party by his independent attitude on various questions, on which his Liberalism outweighed his party loyalty. He would in any case have been incapacitated by an affection of the eyesight, which for a while threatened to withdraw him from public life altogether. After 1895 Mr Courtney's divergences from the Unionist party on questions other than Irish politics became gradually more marked. He became known in the House of Commons principally for his candid criticism of the measures introduced by his nominal leaders, and he was rather to be ranked among the Opposition than as a Ministerialist; and when the crisis with the Transvaal came in 1899, Mr Courtney's views, which remained substantially what they were when he supported the settlement after Majuba in 1881, had plainly become incompatible with his position even as a nominal follower of Lord Salisbury and Mr Chamberlain. Besides numerous essays in the principal reviews, Mr Courtney was the author of the article on "Banking" in the 9th edition of the *Encyclopædia Britannica*, and of the survey of recent British finance in Mr T. H. Ward's *Reign of Queen Victoria* (1887). In his earlier years he was a regular contributor to *The Times*.

**Courtrai,** a town of Belgium, in the province of West Flanders, 27 miles south of Bruges by rail. The foremost industry of the town is the manufacture of linen, but the trade in oil is increasing in importance. Flax is extensively grown in the district. All the large Ulster spinners send delegates to Courtrai, to visit the farmers and attend the marts where raw flax is to be bought in its various qualities, in order to ship it off to their mills under the most advantageous conditions. Population (1880), 26,943; (1890), 30,383; (1897), 32,949.

**Cousins, Samuel** (1801-1887), English mezzotint engraver, was born at Exeter on 9th May 1801. He was pre-eminently the interpreter of Sir Thomas Lawrence, his contemporary. During his apprenticeship to S. W. Reynolds he engraved many of the best amongst the three hundred little mezzotints illustrating the works of Sir Joshua Reynolds which his master issued in his own name. In the finest of his numerous transcripts of Lawrence, such as "Lady Acland and her Sons," "Pope Pius VII.," and "Master Lambton," the distinguishing characteristics of the engraver's work, the brilliancy and force of effect in a high key, corresponded exactly with similar qualities in the painter. After the introduction of steel for engraving purposes in 1823, Cousins and his contemporaries were compelled to work on it, because the soft copper previously used for mezzotint plates did not yield a sufficient number of fine impressions to enable the method to compete commercially against line engraving, from which much larger editions were obtainable. The painter-like quality which distinguished the 18th century mezzotints on copper was wanting in his later works, because the hardness of the steel on which they were engraved impaired freedom of execution and richness of tone, and so enhanced the labour of scraping that he accelerated the work by stipple, etching the details instead of scraping them out of the "ground" in the manner of his predecessors. To this "mixed style," previously used by Richard Earlom on copper, Cousins added heavy roulette and rocking-tool textures, tending to fortify the darks, when he found that the "burr" even on steel failed to yield enough fine impressions to meet the demand. The effect of his prints in this method after Reynolds and Millais was mechanical and out of harmony with the picturesque technique of these painters, but the phenomenal popularity which Cousins gained for his works at least kept alive and in favour a form of mezzotint engraving during a critical phase of its history. Raimbach, the line engraver, dated the decline of his own art in England from the appearance in 1837 of Cousins's print (in the "mixed style") after Landseer's "Bolton Abbey." Such plates as "Miss Peel" after Lawrence (published in 1832); "A Midsummer Night's Dream," after Landseer (1857); "The Order of Release" and "The First Minuet," after Millais (1854 and 1865); "The Strawberry Girl" and "Lavinia, Countess Spencer," after Reynolds; and "Miss Rich," after Hogarth (1873-1877), represent various stages of Cousins's mixed method. It reached its final development in the plates after Millais's "Cherry Ripe" and "Pomona," published in 1881 and 1882, when the invention of coating copper-plates with a film of steel to make them yield larger editions led to the revival of pure mezzotint on copper, which has since rendered obsolete the steel plate and the mixed style which it fostered. The fine draughtsmanship of Cousins was as apparent in his prints as in his original lead-pencil portraits exhibited in London in 1882. In 1855 he was elected a full member of the Royal Academy, to which institution he later gave in trust £15,000 to provide annuities for superannuated artists who had not been so successful as himself. One of the most important figures in the history of British engraving, he died in London, unmarried, on 7th May 1887.

**Couza, Alexander John** (1820–1873), PRINCE OF RUMANIA, was born 20th March 1820 at Husch, and was educated in Paris, Pavia, and Bologna. He entered the diplomatic service of his country, and became Stadtholder of Galatz, and head of a department in the Ministry of the Interior. By his marriage with a daughter of the Boyar Rosetti he became allied to the higher nobility of the country, and in 1848 he joined the patriotic party. On the entry of the Russians he was imprisoned, but managed to escape on an Austrian steamer to Vienna. After their departure he entered the army, and again rose with great rapidity. Elected in 1858 to the Assembly of Moldavia, he became in the same year Minister of War of the united principalities. In the debates upon the Constitution he was chief speaker on the Unionist side, and in 1859 he assumed the government under the title of Prince Alexander John I. He was not recognized by the Porte until 23rd December 1861, on which day the union of the two principalities under the name of Rumania was proclaimed. The Prince made every effort to secure unity and relieve taxation. He suppressed the *corvée*, introduced the Code Napoleon, and caused the adoption of a system of free education and the foundation of the universities of Jassy and Bucarest. His zeal for reforms and for absolute centralization led to incessant conflict and discontent; financial distress supervened; a military conspiracy forced him to abdicate on 23rd February 1866, and led to the election of Prince Carol I. After his abdication, Prince Alexander John spent the remainder of his life chiefly in Paris, Vienna, and Wiesbaden. He died at Heidelberg on 15th May 1873. (G. F. B.)

**Coventry**, a municipal, county, and parliamentary borough of Warwickshire, England, on the Sherbourne, an affluent of the Avon, 94 miles by rail north-north-west of London. A canal communicates with the Trent and Mersey and Birmingham Canal. The derivation of the name from a convent of 1043 seems no longer tenable. A county of itself till 1843, the city in 1888 became a county borough. The corporation consists of a mayor, 10 aldermen, 30 councillors, a treasurer, town clerk, and other officers. In 1885 the parliamentary representation was reduced to one. In 1894 a suffragan bishop, under the See of Worcester, was appointed with the title of bishop of Coventry. Among recent erections are a Baptist, a Congregational, a Primitive Methodist, and a Catholic chapel. A statue (1883) of Sir Thomas White, Lord Mayor of London 1532-33, founder of St John's College, &c., an opera house, and baths. The cemetery, planned by Sir Joseph Paxton, was extended in 1887. The present buildings of the Free Grammar School were opened in 1885. A technical school (1887) was enlarged in 1894. Besides Swanswell (1883) and Spencer Park (1883), there is a recreation ground (1880) of twelve acres. A daily paper is issued. Area of municipal borough, 3093 acres. Population (1881), 44,831; (1891), 52,724; (1901), 69,877.

**Coventry**, a town of Kent county, Rhode Island, U.S.A., with an area of 17 square miles of hill country, interspersed with ponds. It contains a few small villages, but the population is mainly rural. It is traversed by the New England Railway. Population (1900), 5279.

**Covilhã,** a town of Portugal, district Castello Branco, on the east versant of the Serra da Estrella, near the river Zezere, 30 miles north from Castello Branco. some 4000 operatives are employed in manufacturing cloth. Population (1900), 15,527.

**Covington,** a city of Kenton county, Kentucky, U.S.A. It is situated in 39° 05′ N. lat. and 84° 36′ W. long., on the south bank of the Ohio river, opposite Cincinnati, with which it is connected by three bridges and by ferries. Two railways, the Chesapeake and Ohio and the Louisville and Nashville, pass through it. In 1890 the capital invested in manufactures was $6,900,000, the number of hands employed was 7600, and the output was valued at $16,000,000. In 1899 the assessed valuation of all property, real and personal, was $21,468,444, the tax rate $30.25 per $1000, and the net debt $2,195,544. To its proximity to Cincinnati, of which it is practically a suburb, it owes its rapid growth. Population (1880), 29,720; (1890), 37,371; (1900), 42,938, including 2487 negroes. The death-rate in 1900 was 20·2.

**Cowasjee Jehanghier Readymoney,** SIR (1812–1878), "the Peabody of Bombay." Early in the 18th century three Parsee brothers moved from Nowsaree, near Surat, in Gujarat, to Bombay, and became the pioneers of a lucrative trade with China. They gained the sobriquet of "Readymoney," which they adopted as a surname. Only Heerjee Jewanjee Readymoney left issue, two daughters, the elder of whom married a Banajee, and the younger a Dady Sett. The son of the former, Jehanghier Heerjee, married Meerbae, the daughter of the latter, and was made the heir not only of his grandfather but of his two grand-uncles. The younger of their two sons was Cowasjee Jehanghier. His only English education was at the then well-known school kept by Serjeant Sykes in the Fort of Bombay. At the age of 15 he entered the firm of Duncan, Gibb, & Co. as "godown keeper," or warehouse clerk. In 1837 he was promoted to the highly responsible and lucrative appointment of "guarantee broker" to two of the leading European firms of Bombay. In 1846 he was able to begin trading on his own account. He was made a J.P. for the town and island of Bombay, and a member of the Board of Conservancy; and in 1866 was appointed a Commissioner of Income Tax, his tactful management being largely responsible for the fact that this tax, then new to Bombay and most unpopular, was levied with unexpected financial success. He was made C.S.I. in 1871; and in 1872 he was created a Knight Bachelor of the United Kingdom, and his statue, by T. Woolner, R.A., was erected in the town-hall. His donations to the institutions of Bombay amounted to close on £200,000. His health broke down in 1871, and he died in 1878, being succeeded by his son, Sir J. Cowasjee Jehanghier [Readymoney], who was himself created a Knight Bachelor in 1895. (M. M. BH.)

**Cowdenbeath,** a mining town and police burgh of Fifeshire, Scotland, situated near the Cowdenbeath station of the North British Railway, 5 miles east-north-east of Dunfermline. The town is mainly occupied by miners. It possesses a public hall. The Police Act was adopted in 1890. Population (1891), 4249; (1901), 7466.

**Cowen, Frederic Hymen** (1852——), English musical composer, was born at Kingston, Jamaica, on 29th January 1852. At four years old he was brought to England, where his father became treasurer to the opera at Her Majesty's Theatre, and private secretary to the Earl of Dudley. His first teacher was Henry Russell, and his first published composition appeared when he was but six years old. He studied the piano with Benedict, and composition with Goss; in 1865 he was at Leipzig under Hauptmann, Moscheles, Reinecke, and Plaidy. Returning home on the outbreak of the Austro-Prussian War, he appeared as a composer for the orchestra in an overture played at the Promenade Concerts at Covent Garden in

September 1866. In the following autumn he went to Berlin, where he was under Kiel, at Stern's conservatorium. A symphony and a piano concerto were given in St James's Hall in 1869, and from that time Cowen has been recognized as primarily a composer, his talents as a pianist being subordinate, although his public appearances were numerous for some time afterwards. His cantata, *The Rose Maiden*, was given in London in 1870, his second symphony by the Liverpool Philharmonic Society in 1872, and his first festival work, *The Corsair*, in 1876 at Birmingham. In that year his opera, *Pauline*, was given by the Carl Rosa Company with moderate success. In 1884 he conducted five concerts of the Philharmonic Society, and in 1888, on the resignation of Sullivan, became the regular conductor of the society, resigning the post in 1892. In the year of his appointment, 1888, he went to Melbourne as the conductor of the daily concerts given in connexion with the Exhibition there. In 1896 Cowen was appointed conductor of the Liverpool Philharmonic Society and of the Manchester orchestra, in succession to Sir Charles Hallé. In 1899 he was reappointed conductor of the Philharmonic Society. His works include:—Operettas: *Garibaldi* (1860) and *One Too Many* (1874); operas: *Pauline* (1876), *Thorgrim* (1890), *Signa* (Milan, 1893), and *Harold* (1895); oratorios: *The Deluge* (1878), *St Ursula* (1881), *Ruth* (1887), *Song of Thanksgiving* (1888), *The Transfiguration* (1895); cantatas: *The Rose Maiden* (1870), *The Corsair* (1876), *The Sleeping Beauty* (1885), *St John's Eve* (1889), *The Water Lily* (1893), *Ode to the Passions* (1898), besides a large number of short cantatas for female voices; an enormous number of songs, ranging from the popular "ballad" to really artistic lyrics, anthems, part-songs, duets, &c.; six symphonies, among which No. 3, the "Scandinavian," has had the greatest success; four overtures; suites, *The Language of Flowers* (1880), *In the Olden Times* (1883), *In Fairyland* (1896); four English dances (1896); a concerto for piano and orchestra, and a fantasia for the same played by M. Paderewski (1900); a quartet in C minor, and a trio in A minor, both early works; pianoforte pieces, &c. Cowen is never so happy as when treating of fantastic or fairy subjects; and whether in his cantatas for female voices, his charming *Sleeping Beauty*, his *Water Lily*, or his pretty overture, *The Butterfly's Ball* (1901), he succeeds wonderfully in finding graceful expression for the poetical idea. His dance music, such as is to be found in various orchestral suites, is refined, original, and admirably instrumented; and if he is seldom as successful in portraying the graver aspects of emotion, the vogue of his semi-sacred songs is a thing that cannot be ignored. That none of his operas has been permanently successful is a mischance which they share with most of the serious dramatic music of Great Britain; but even in more favourable conditions their lack of the great qualities, of the sincere emotion that comes from the heart and goes to the heart, would seriously impede their popularity. Charmingly melodious as he always is in his lighter moods, Cowen often contents himself with musical ideas that are less than beautiful in writing for the stage.

**Cowen, Joseph** (1831–1900), English politician, son of Sir Joseph Cowen, a prominent citizen and mine-owner of Newcastle-on-Tyne, was born in 1831, and was educated at Edinburgh University. In 1874 he was elected member of Parliament for the borough on the death of his father, who had held the seat as a Liberal since 1865. Joseph Cowen was at that time a strong Radical on domestic questions, an advocate of co-operation, an admirer of Garibaldi, Mazzini, and Kossuth, a sympathizer with Irish Nationalism, and one who in speech, dress, and manner identified himself with the North-country mining class. Short in stature and uncouth in appearance, his individuality first shocked and then by its earnestness impressed the House of Commons; and his sturdy independence of party ties, combined with a gift of rough but genuine eloquence (of which his speech on the Royal Title Bill of 1878 was an example), rapidly made him one of the best known public men in the country. He was, moreover, an Imperialist and a Colonial Federationist at a time when Liberalism was tied and bound to the Manchester traditions; and, to the consternation of the official wire-pullers, he vigorously supported Disraeli's foreign policy, and in 1881 opposed the Gladstonian settlement with the Boers. His independence (which his detractors attributed in some degree to his alleged susceptibility to Tory compliments) brought him into collision both with the Liberal caucus and with the party organization in Newcastle itself, but Cowen's personal popularity and his remarkable powers as an orator triumphed in his own birthplace, and he was again elected in 1885 in spite of Liberal opposition. Shortly afterwards, however, he retired both from Parliament and from public life, professing his disgust at the party intrigues of politics, and devoted himself to conducting his newspaper, the *Newcastle Daily Chronicle*, and to his private business as a mine-owner. In this capacity he exercised a wide influence on local opinion, and the revolt of the Newcastle electorate in later years against doctrinaire Radicalism was largely due to his constant preaching of a broader outlook on national affairs. He continued behind the scenes to play a powerful part in forming North-country opinion until his death on 17th February 1900. (H. CH.)

**Cowes,** or West Cowes, a town, railway station, and seaport in the Isle of Wight parliamentary division of Hampshire, England, on the north coast of the island, west side of the Medina estuary, 11½ miles south-south-east of Southampton, and in daily communication with the mainland. A new esplanade has been formed, and a new public pier constructed. At East Cowes, on the opposite side of the Medina, a recreation ground has been opened, and a home for aged seamen provided. Each town forms a parish under an Urban District Council (1894). Area of West Cowes, 576 acres. Population (1891), 7690; (1901), 8654. Area of East Cowes, 510 acres. Population (1891), 2934; (1901), 3180. The harbour between the two towns is now subject to an elective body of commissioners. The registered shipping at the end of 1899 amounted to 258 vessels of 11,284 tons. In 1899, 25,984 vessels of 2,483,969 tons entered, and 25,929 of 2,480,093 tons cleared.

**Cowpens,** a village of Spartanburg county, South Carolina, U.S.A., situated in the northern part of the state. It was here, in 1781, during the Revolution, that General Morgan defeated the British under Colonel Tarleton, when the latter lost 800 men in killed, wounded, and prisoners, and the Americans 72.

**Cox, Rev. Sir George William,** 14TH BART. (1827–1902), English historian, son of Mr G. H. Cox, and nephew of the thirteenth baronet, was born 10th January 1827 at Benares, India, and was educated at Rugby and Trinity College, Oxford. In 1850 he was ordained, and worked as a curate till 1860, when he took a mastership at Cheltenham College, which he only held for a year. He had already contributed to the *Edinburgh Review*, and had published (1850) *Poems, Legendary and Historical* (with Edward A. Freeman), and (1853) a *Life of St Boniface*. In 1861 he became literary adviser to Messrs Long-

man, and devoted himself to literary work, connected chiefly with history and comparative mythology. His published books include (1861) *Tales from Greek Mythology*, (1867) *A Manual of Mythology*, (1870) *Latin and Teutonic Christendom*, and *The Mythology of Aryan Nations*, (1874) *History of Greece*, 2 vols., (1876) *The Athenian Empire*, (1876) *General History of Greece*, (1881) *History of British Rule in India*, and *Introduction to Comparative Mythology*, (1886) *Lives of Greek Statesmen*, (1887) *Concise History of England*. Of these works, some of them avowedly written for popular purposes and successful in that object, the most important was the larger *History of Greece*, begun in 1874, which, though showing the inspiration of Grote, was at the same time a conscientious rehandling of the materials as they then existed. Similarly his studies in mythology were inspired by Max Müller, but his treatment of the subjects was his own. Sir George Cox (who succeeded to the baronetcy in 1877) was a Broad Churchman, and became known as a prominent supporter of Bishop Colenso in 1863–65; and five years after Colenso's death he published (1888) his *Life* of the Bishop. In 1881 Sir G. Cox was made vicar of Scrayingham, York, but resigned the living in 1897. In 1896 he was given a Civil List Pension. He died at Walmer on 9th February 1902.

**Coxe, Henry Octavius** (1811–1881), Bodley's librarian at Oxford, was born at Bucklebury, in Berkshire, 20th September 1811, and was educated at Westminster School and Worcester College, Oxford. Immediately on taking his degree in 1833 he began work in the Manuscript Department of the British Museum, became in 1838 sub-librarian of the Bodleian, and in 1860 succeeded Dr Bandinel as head librarian, an office he held until his death in 1881. Having proved himself an able palæographer, he was sent out by the British Government in 1857 to inspect the libraries in the monasteries of the Levant, and his investigations determined the character of the existing remains in the districts he visited. One valuable result of his travels was the detection of the forgery attempted by M. Simonides. He was the author of various catalogues, and under his direction that of the Bodleian, in more than 720 volumes, was completed. He published *Rogeri de Wendover Chronica*, 5 vols. (1841–44); the *Black Prince, an historical poem written in French by Chandos Herald* (1842); and *Report on the Greek Manuscripts yet remaining in the Libraries of the Levant* (1858). He was not only an accurate librarian but an active and hard-working clergyman, and was for the last twenty-five years of his life in charge of the parish of Wytham, near Oxford. He was likewise honorary fellow of Worcester and Corpus Christi Colleges. He died on 8th July 1881.

**Cracow** (Polish, *Kraków*; German, *Krakau*), the second city of the Austrian crownland of Galicia. Population in 1890, 74,593; in 1900, 91,310, chiefly Polish and Roman Catholic (estimated to have 7 per cent. German and 15 per cent. Czech; 28 per cent. Jewish, 1 per cent. Greek Catholic, and 1 per cent. Protestant). It is one of the strongest Austrian fortresses (of which there are two in Galicia, the second being Przemysl), with a garrison of 6000 men. In 1889 the Catholic bishop was raised to the rank of prince. Cracow now contains, in addition to its 39 churches and numerous chapels, 7 synagogues and 25 religious communities. Many of the old buildings have been restored, such as the Church of St Mary, decorated by the celebrated Polish artist Matejko, and the Tuchhaus, which now contains a collection of pictures by Polish painters; while important new structures have been erected. The latter comprise the new university (1881–87), an imposing Gothic edifice which accommodates the Polish Academy of Science (founded in 1872), a library, and archæological and other collections; together with a new theatre (1891–93) in the late Renaissance style. The university, in which the Polish language has been in exclusive use since 1870, has a staff of 157 professors and lecturers, and is attended by 1300 students. The other educational institutions include a theological seminary, 2 training colleges, 3 gymnasia, a realschule, 3 technical and special schools, and an academy of fine art, which was under the control of the painter Matejko up to the time of his death. Industry, which has undergone little change, now comprises the manufacture of machinery, wax candles, matches, and oil, together with brewing and corn-milling, in addition to its staples, cloth and leather. Its commerce is of greater importance, and includes corn, timber, salt and wine, pigs and textiles, eggs and butter, together with a considerable transit and commission trade with Hungary, Silesia, and other parts of Galicia. The Jewish population has an exceptionally large share in the high proportion of illegitimacy, 44 per cent. While the illegitimate births among the Catholics were less than one-third, they formed over two-thirds of the whole among the Jews. On the other hand, the Jewish death-rate (20·87 per thousand) is comparatively low as compared with that of the entire Christian population (24·82). (Æ. O'N.)

**Cradock,** a town of Cape Colony, in the upper valley of the Great Fish River, nearly due north of Port Elizabeth, and about midway between that place and Colesberg, with both of which it is connected by rail. It is one of the chief centres of the wool trade, and in 1891 had a population of 4390. In the neighbouring district still survive a few herds of quaggas, which are now protected by the game laws.

**Craik, Dinah Maria** (1826–1887), English novelist, better known by her maiden name of Mulock, and still better as "the author of *John Halifax, Gentleman*," was the daughter of Thomas Mulock, an eccentric religious enthusiast of Irish extraction, and was born on 20th April 1826 at Stoke-upon-Trent, in Staffordshire, where her father was the minister of a small congregation. She settled in London about 1846, determined to obtain a livelihood by her pen, and, beginning with fiction for children, advanced steadily until *John Halifax, Gentleman* (1857), placed her in the front rank of the female novelists of her day. *A Life for a Life* (1859), though inferior, maintained a high position, but she afterwards wrote little of importance except some very charming tales for children. Her most remarkable novels, after those mentioned above, were *The Ogilvies* (1849), *Olive* (1850), *The Head of the Family* (1851), *Agatha's Husband* (1853). There is much passion and power in these early works, and all that Mrs Craik wrote was characterized by high-mindedness, principle, and deep, warm feeling. Some of the short stories in *Avillion, and other Tales* also exhibit a fine imagination. She also published poems distinguished by genuine lyrical spirit, narratives of tours in Ireland and Cornwall, and *A Woman's Thoughts about Women*. She married Mr G. L. Craik, publisher, in 1864, and died at Shortlands, near Bromley, 12th October 1887.

**Craiova** or **Krajova,** a town in Rumania, the ancient capital of Little Wallachia, now seat of the prefect of the district of Dolj. It is of considerable commercial importance, the province of which it is the capital being very rich in grain, pasturage, and vegetable products, besides containing extensive forests. Near Craiova is a large military tannery (penitentiary), besides rope and carriage factories. There are 27 Orthodox churches, 1 Roman Catholic, 1 Protestant church, and 5 synagogues. Craiova is also the seat of a Court of Appeal, a Court of

First Instance, and a Chamber of Commerce, as well as the headquarters of the first Army Corps. The ancient bans of Craiova had the right of striking their coins with their own effigies, whence the designation "bani" (centimes) given to the copper coinage of Rumania. The monetary unit "leu" (*leo*, lion) also comes from this district. The principal exports are cereals and fish, linen, pottery, and leather. The principal trade carried on consists of agricultural products and cattle. Population (1895), 41,000; (1900), 45,438, of whom about 3000 are Jews.

**Cranbrook, Gathorne Gathorne-Hardy,** 1st Earl of (1814——), British statesman, born at Bradford, in Yorkshire, 1st October 1814, was the son of John Hardy, for many years one of the members for the borough. This circumstance seemed to give him a claim upon the suffrages of the electorate, and upon entering upon active political life in 1847, eleven years after his graduation at Oxford, and nine years after his call to the Bar, he offered himself as a candidate, but was unsuccessful. In 1856 he was returned for Leominster, and in 1865 defeated Mr Gladstone at Oxford. In 1866 he became President of the Poor Law Board in Lord Derby's new administration. When in 1867 Mr Walpole resigned, from dissatisfaction with Mr Disraeli's Reform Bill, Mr Gathorne-Hardy succeeded him at the Home Office. In 1874 he was Secretary for War; and when in 1878 Lord Salisbury took the Foreign Office upon the resignation of Lord Derby, Viscount Cranbrook (as Mr Hardy became within a month afterwards) succeeded him at the India Office. In Lord Salisbury's administrations of 1885 and 1886 Lord Cranbrook was President of the Council, and upon his retirement from public life concurrently with the resignation of the Cabinet in 1892 he was raised to an earldom.

**Cranston,** a town of Providence county, Rhode Island, U.S.A., with an area of 30 square miles. It contains several villages, among them Cranston, Pontiac, and Natick. It is traversed by branches of the New York, New Haven, and Hartford Railway. Population (1880), 5940; (1890), 8099; (1900), 13,343.

**Crawford, Francis Marion** (1854——), American author, was born at Lucca, Italy, on 2nd August 1854, being the son of the American sculptor Thomas Crawford (long a resident of Italy), and the nephew of Julia Ward Howe, the American poet. He studied successively at St Paul's School, Concord, New Hampshire; Cambridge University; Heidelberg; and Rome. In 1879 he went to India, where he edited the Allahabad *Indian Herald*, meanwhile noting the effect of Indian life upon British subjects. Returning to America, he studied Sanscrit and Zend at Harvard University for a year, contributed to various periodicals, and in 1882 produced—at the suggestion of his uncle Samuel Ward, a New York club-man and *raconteur*—his first novel, *Mr Isaacs, a Tale of Modern India*, in which he mingled character sketches of two races, romanticism, supernaturalism, and plain realism in a manner which gave the story an immediate place in contemporary fiction. After a brief residence in New York and Boston, Crawford, in 1884, returned to Italy, where he made his permanent home, thenceforward producing volume after volume in rapid succession. *An American Politician* (1884) may be taken as representative of his tales of American life; *A Roman Singer* (1884), *Saracinesca* (1887), and its sequel *Sant' Ilario* (1889), and *A Cigarette-Maker's Romance* (1890), being examples of his dealing with Italian subjects; while of books not fiction the most conspicuous is *Ave Roma Immortalis* (1898), a survey of the history, architecture, and characteristics of Rome—bird's-eye views to which Crawford brought sympathy and knowledge, writing at once as a Roman Catholic and a cosmopolitan.

**Crawfordsville,** capital of Montgomery county, Indiana, U.S.A., situated on Sugar Creek, in the western part of the state, at an altitude of 780 feet. It is on three great railway lines, the Vandalia, the Cleveland, Cincinnati, Chicago, and St Louis, and the Chicago, Indianapolis, and Louisville. Wabash College, a non-sectarian institution, founded here in 1832, had in 1899 a faculty of 21 professors and an attendance of 189. Population (1880), 5251; (1900), 6649.

**Creatianism and Traducianism.**—Traducianism is the doctrine about the origin of the soul which was taught by Tertullian in his *De Anima*—that souls are generated from souls in the same way and at the same time as bodies from bodies: Creatianism is the doctrine that God creates a soul for each body that is generated. The Pelagians taunted the upholders of original sin with holding Tertullian's opinion, and called them Traduciani (from *tradux*: *vid.* Du Cange *s.vv.*), a name which was perhaps suggested by a metaphor in *De An.* 19, where the soul is described "velut surculus quidam ex matrice Adam in propaginem deducta." Hence we have formed "traducianist," "traducianism," and by analogy "creatianist," "creatianism." St Augustine denied that Traducianism was necessarily connected with the doctrine of original sin, and to the end of his life was unable to decide for or against it. St Jerome condemned it, and said that the other was the opinion of the Church, though he admitted that most of the Western Christians held Traducianism. The question has never been decided, but Creatianism, which had always prevailed in the East, became the general opinion of the mediæval theologians, and Peter Lombard's *creando infundit animas Deus et infundendo creat* was an accepted formula. Luther, like St Augustine, was undecided, but Lutherans have as a rule been Traducianists. Calvin favoured Creatianism.

Peter Lombard's phrase perhaps shows that even in his time it was felt that some union of the two opinions was needed, and St Augustine's toleration pointed in the same direction, for the Traducianism he thought possible was one in which God *operatur institutas administrando non novas instituendo naturas* (*Ep.* 166. 5. 11). Modern psychologists teach that while "personality" can be discerned in its "becoming," nothing is known of its origin. Lotze, however, who may be taken as representing the believers in the immanence of the divine Being, puts forth—but as a "dim conjecture"—something very like Creatianism (*Microcosmus*, bk. iii. chap. v. *ad fin.*). It is still, as in the days of St Augustine, a question whether a more exact division of man into body, soul, *and spirit* may help to throw light on this subject. See indices to *Augustine*, vol. xi., and *Jerome*, vol. xi., in Migne's *Patrologia, s.v.* "Anima"; Delitzsch, *Biblical Psychology*, ii. § 7; sections on "Tertullian and Pelagianism" in Neander's *Hist. Ch.*; Liddon, *Elements of Religion*, Lect. iii.; Mason, *Faith of the Gospel*, iv. §§ 3, 4, 9, 10.

(A. N*.)

**Crediton,** a market-town in the South Molton parliamentary division of Devonshire, England, on the Creedy, 8 miles north-west of Exeter by rail. The ancient church has been restored, and in 1897 Crediton became the head of a suffragan bishopric. Recent structures are a temperance hall, the town-hall (rebuilt), and water-works. Tanning and the making of confectionery and cider have been introduced. Area of urban district, 947 acres. Population (1881), 4165; (1901), 3974.

**Creede,** capital of Mineral county, Colorado, U.S.A., situated in a narrow cañon tributary to the Rio Grande, in the San Juan Mountains, in the south-western part of the state. It owes its existence to rich silver mines developed in 1891 in its vicinity. Within two years it had acquired a population of several thousands, and a branch of

the Denver and Rio Grande Railway had been extended to it. In 1892 most of the business portion was destroyed by fire. Soon afterwards the reduction in the price of silver caused the closing down of most of the mines, and in 1900 the place had a population of only 938.

**Creeds.**—I. *The Apostles' Creed.*—Recent researches have confirmed the importance of Ussher's discovery that the creed presented by Marcellus, bishop of Ancyra, to Julius, bishop of Rome, in 341, was the Old Roman Creed (cited as R), which Rufinus some fifty years later compared with the creed of the Church of Aquileia. R is the archetype of all Western forms. It preserves the simplicity of the catechetical teaching given in the early years of the 2nd century, to which it can be traced back in quotations by Novatian, Dionysius, Tertullian. Even the heretic Marcion may be called as a witness to the fact that the words "holy Church" were found in this the creed of his baptism (before 145). The relation of R to Eastern creeds is disputed. Some writers (Kattenbusch, Harnack) maintain that it is the sole archetype, having been brought to Antioch in the 3rd century and spread by the influence of the school of Lucian the Martyr. Others (Zahn, Sanday) find traces of an Eastern archetype in Justin Martyr and Irenæus, to be traced with R to a common origin in "a baptismal confession which had already assumed a more or less stereotyped form in early apostolic times." The question is complicated by the discovery of new materials (*e.g.*, creeds of Marcus, hermit of Ancyra, and Serapion, bishop of Thmuis in Egypt), which are said to confirm the theory that local creeds existed in the 3rd century which were independent of R. Increasing value is set on the baptismal formula (Matt. xxviii. 19) as the seed-thought of later creeds, though there is reason to believe that the Eunuch's creed, interpolated in the text of Acts viii. 37: "I believe that Jesus is the Son of God," was the creed of the apostles (cp. Rom. x. 9; 1 Cor. xii. 3; 1 John iv. 15, v. 5; Heb. iv. 14). It was known to Irenæus (iii. 12. 8), and represents the form of baptismal confession used in the Church of Asia Minor, from which he drew his tradition. The history of the received text of the Apostles' Creed is still obscure. The additional phrases, which distinguish it from R, are found in Gallican creeds of the 5th century, with one exception, "maker of heaven and earth." This had found a place in the Dacian Creed of Niceta, bishop of Remesiana (*c.* 400). The received text is found in a group of documents containing liturgical pieces and sermons of mixed Roman and Gallican origin (so-called Gallican Missal and Gallican Sacramentary), then in the treatise of the Benedictine monk Pirminius (*c.* 730). The usual opinion is that it was brought under the influence of a Frankish emperor from Gaul to Rome, where (as some suppose) the Nicene Creed (Constantinopolitan form) had been substituted for R. But the evidence of a Psalter attributed to Pope Gregory III. (*c.* 731), indications that Pirminius used the Roman service of Baptism, and some evidence that R had not been given up, have led to the suggestion that R was enlarged by the Roman Church (Burn).

II. *The Nicene Creed* of the Liturgies is the old Baptismal Creed of Jerusalem as taught in the Catechetical Lectures of Cyril (*c.* 345), revised after 360 by the insertion of phrases from the Creed of the Nicene Council of 325. It was quoted by Epiphanius in his *Ancoratus* (374), and in 381 found a place in the minutes of the Council of Constantinople, from which it was quoted at Chalcedon as "the exposition of the 150 Fathers," being regarded as an improved recension of the first Nicene Creed. It was brought before the Council of 381, either to vindicate the orthodoxy of Cyril, its author (Hort), or as the Baptismal Confession of Nektarius, who (though unbaptized) was elected president after the death of Meletius (Kunze). The question is still undecided, but there is reason to believe that it was used as the Baptismal Creed of Constantinople after 383, and was accepted as such by the Monophysites, who rejected the Definition of the Council of Chalcedon. At Chalcedon it was approved by the Pope's legates, probably as containing in the words "incarnate by the Holy Ghost and the Virgin Mary" a parallel to the teaching of R, on which Leo laid stress in his letter to Flavian. If the Stowe Missal represents the Roman Liturgy of the 5th century (Probst), the creed was introduced into that Liturgy much earlier than is usually supposed.

III. *The Athanasian Creed.*—A MS. has lately been found in the library of the Marist Fathers at Lyons, which was given by Bishop Leidrad (†814) to the Altar of St Stephen, with an autograph inscription. It contains this creed in a collection which he apparently used on his journey into Spain to confute the Adoptionists. This one MS. disproves the argument (Swainson, Lumby) that the creed in its present form was not known to theologians during the 8th century. Some eight other MSS. may be assigned to the 8th century. Behind these MSS. are early commentaries which quote the text, the earliest (Fortunatus) probably of the 6th century. The more important quotations from both parts of the creed by the Council of Toledo in 633, Cæsarius of Arles (†543), Avitus of Vienne (†523), enable us to trace it back in its present form to the 5th century. A new theory of growth from an unpolished sermon like that in the Trèves fragment (Loofs), is based on the doubtful supposition that it was unknown to Isidore, who presided over the Council of Toledo in 633, but assumes the original unity of the document. The authorship is unknown, but the names of Vincentius (Ommanney) and Honoratus, founder of the monastery of Lerins (Burn), have been suggested. Internal evidence shows that it was written as an Instruction on the Faith, probably before the condemnation of Nestorius in 431. It was not introduced into Psalters as a canticle till *c.* 800.

The history of later confessions of faith is not disputed.

**Crefeld,** a town of Prussia, in the Rhine province, 34 miles by rail north-north-west from Cologne and 4 miles west from the Rhine. It is the chief centre in Germany for the manufacture of velvets and silks; in addition to which there are dyeworks, stuff printing and stamping works, engineering and machine shops, chemical, sugar, and other factories, distilleries, tanneries, &c. The town-hall has been decorated with frescoes by P. Janssen, and the royal weaving school with mural paintings by A. Baur illustrating the development of the silk industry. The Emperor William Museum was opened in 1897. There are monuments to Moltke, Bismarck, K. Wilhelm (com-

poser of *Die Wacht am Rhein*), and the war of 1870–71. The places of worship include a Mennonite church and a synagogue. Population (1885), 90,236; (1900), 106,887.

**Creighton, Mandell** (1843–1901), English historian and Bishop of London, was born at Carlisle on 5th July 1843, being the eldest son of Robert Creighton, a merchant of that city. He was educated at Durham Grammar School and at Merton College, Oxford, where he was elected to a postmastership in 1862. He obtained a first class in classical moderations in 1864, followed by a first in *literæ humaniores* and a second in law and modern history in 1866. In the same year he was elected fellow of Merton, becoming tutor immediately afterwards. He was ordained deacon, on his fellowship, in 1870, and priest in 1873; in 1872 he had married Louise, daughter of Robert von Glehn, a London merchant (herself a writer of several successful books of history), the marriage being a very happy one. Meanwhile he had rapidly come to the fore in the university as a profound student of men and things, a brilliant teacher, and a wise and trustworthy friend; and before he left Oxford he had attained to a position and an influence which was "exceptional and even pre-eminent." He had already published several smaller historical works, but his crowded life left little room for writing; and in 1875, with rare wisdom and self-restraint, he left Oxford to become vicar of Embleton, a parish on the coast of Northumberland, near Dunstanburgh, and within reach of the fine library in Bamburgh Keep, with an ancient and beautiful church and a fortified parsonage house. Here he remained for nearly ten years, devoting himself to his parish and acquiring that intimate knowledge of parochial work which afterwards stood him in such good stead, taking private pupils, studying and writing, as well as taking an active part in diocesan business. Amongst his parishioners was Sir George Grey of Fallodon, Home Secretary at the time of the Chartist riots; he and Creighton became close friends, and on his death the vicar wrote a beautiful memoir of him which was privately printed. Here too he planned and wrote the first two volumes of his chief historical work, the *History of the Papacy*; and it was in part this which led to his being elected in 1884 to the newly founded Dixie Professorship of Ecclesiastical History at Cambridge. Creighton visited Cambridge in the Michaelmas term of 1884, but did not come into residence till early in 1885. He found in his new university, as he said, not a *noverca* but an *alma mater*, and one perhaps in some ways more congenial than Oxford. His influence at once made itself felt. To him more than to any other was due the reorganization of the historical school at Cambridge, which was at first far too narrowly political, on broader and more truly historical lines. His lectures and conversation classes were extraordinarily good, and no man could have been more generous in helping students, men and women, than he was. He was a born teacher, and unlike some other great teachers, he had the gift of imparting truth and kindling enthusiasm without in any way curbing the individuality of those who came under his influence. In 1886 he combined with other leading historians to found the *English Historical Review*, which during his five years of editorship acquired the high standard of excellence which it has since maintained. In 1886, too, he represented Emmanuel College at the centenary of its offshoot, Harvard College in Massachusetts. Meanwhile, the vacations were spent at Worcester, where he had been nominated a Canon Residentiary in 1885, and where his sermons and courses of historical lectures were greatly valued. In 1891 he was made Canon of Windsor; but he never went into residence, for in the same year, with great searchings of heart and after anxious consultation of friends, he accepted the see of Peterborough. He threw himself eagerly into his new work, visiting and preaching in every part of his diocese, lecturing in great towns and conferring with working men (he became an Oddfellow that he might be in fuller sympathy with them), using his influence with churchmen and dissenters alike, and in social work of all kinds. Nor did the diocese absorb his energies: he found time to preach and lecture elsewhere, and to deliver remarkable speeches at social functions; he worked hard with Archbishop Benson on the Parish Councils Bill (1894); he became the first president of the Church Historical Society (1894), and continued in that office till his death; he took part in the Laud Commemoration (1895); he represented the English Church at the coronation of the Tsar (1896). He even found time for academical work, delivering the Hulsean Lectures (1893–94) and the Rede Lecture (1894) at Cambridge, and the Romanes Lecture at Oxford (1896).

On the translation of Dr Temple to Canterbury, Bishop Creighton was, in accordance with general expectation, called to London; and his election was confirmed on January 15, 1897. In accepting the see he fully realized the immensity of a burden which circumstances had made exceptionally great. During Dr Temple's bishopric ritual divergencies of all kinds had grown up, which left a very difficult task to his successor. More especially was this the case in view of the public clamour on the subject, partly political and partly fanatical, which was just then arising. Of all this agitation Creighton naturally bore the brunt. He set himself to work without undue haste, investigating and experimenting, studying the facts and endeavouring to grasp their real significance, and meanwhile dealing with particular points as they arose. He knew how to suffer fools gladly: he knew how to enter into a point of view that was not his own. As was only natural, his studied fairness and moderation did not satisfy partisans on either side; and his efforts towards conciliation, marked by an unusual appreciation of the aims of both parties, laid him open to much misunderstanding. His administration has been subjected to hostile criticism from various and contradictory points of view; but it did much, in a period of almost unexampled difficulty, to preserve peace and foster the spirit of loyalty. He is credited with having suggested the reference to the Archbishops of the questions of Reservation and the use of Incense; and it was his express direction, when the hearing took place, that those who appeared on his behalf should do everything possible to elucidate the truth. He strained every nerve to induce his clergy to accept his ruling in accordance with the Archbishops' opinion; but when, during his last illness, a prosecutor brought proceedings against the clergy of five recalcitrant churches, the Bishop, on full consideration, and on the advice of his Archdeacons, interposed his veto. One other effort on behalf of peace may be mentioned. In accordance with a vote of the Diocesan Conference, the Bishop arranged a "Round Table Conference" between representative members of various parties, to be held at Fulham in October 1900, on "the doctrine of the Holy Eucharist and its expression in Ritual," and a report of its proceedings was published with a preface by him.

No mistake could be greater, however, than to regard things of this kind as the chief events of his episcopate. What concerned him most in them was not the fact of agitation against particular usages, but the fact that principles of true liberalism seemed to have prevailed so little, and that people were so anxious to withhold from others the very liberty which they claimed for themselves. The

true work of his episcopate was positive, not negative; and the gifts which made him a good historian made him also a great bishop. He knew how to rule, and he ruled in stately fashion, wearing cope and mitre on great occasions. All who came to consult him found him a tender-hearted and sympathetic counsellor, whose fatherly wisdom was only the more conspicuous for its unassuming simplicity and its sound common sense. His chairmanship turned the London Church Congress of 1899, which had been regarded as a doubtful experiment, into an unqualified success. He realized as few did the office and message of the English Church in Christendom, and its witness on behalf of something greater than either sectarianism or undenominationalism. He was never tired of reiterating the essential truths to which the English Church bears witness, of directing attention to the great principles which underlie details of practice. Here too his position lay open to obvious misunderstanding, as being a mere glorification of insular Anglicanism. But his discernment of the truths which the English Church aims at presenting never blinded him to the faults of the presentation, and no man was less insular than he. There was yet another side to his work which was wider still. His interests and his sympathies extended to every side of human life; and from the first he took a foremost part in almost every good work that went on in his diocese, social or educational, political or religious. To describe this in detail would be impossible; but it went on continuously, and through it his influence with thinking men and women increased steadily. No period could well have been fuller of fruitful work than the four years of his episcopate, and certainly nothing could have been fuller of promise for the future. But the promise was not destined to be fulfilled. By degrees the work, and especially the routine work, began to tell on him. He fell seriously ill in the late summer of 1900, and the illness developed into ulceration of the stomach. At length, on 14th January 1901, he passed away, and was buried in St Paul's Cathedral on January 17.

Bishop Creighton's publications are too numerous to be spoken of in detail; they range in size from an excellent little primer of Roman History to his *History of the Papacy*, a work of great and enduring value. He was a notable preacher: a Greek ecclesiastic who heard him frequently, knowing then little English, said that there were two words which recurred constantly in his sermons, *sympathy* and *character*; and the implied description is a true one. He was a man of striking presence, with a resonant voice, and clear-cut delicate features, recalling those of the great Englishmen of Tudor days. He was a man of such unusual brilliance (people used to call him "the Admirable Crichton") that many failed to see all that lay beneath it. His irrepressible and often daring humour, his frank distaste for much conventional religious phraseology, and his readiness to accept people at their own standard and make the best of them, caused him to be little appreciated by some good people. But beneath it all there was profound wisdom and piety, extraordinarily wide sympathy, and a holy love of truth. He grew visibly with each new call upon him, and few modern bishops have made so wide and so deep an impression on their age as he did. (W. E. CO.)

**Creil,** a town of France, arrondissement of Senlis, in the department of Oise, on the river Oise, 22 miles in direct line south-east of Beauvais, and an important junction on the railway from that place to Paris. The manufacture of machinery, heavy iron goods and nails, and copper and iron founding, are important industries; earthenware is also manufactured. The church is a mediæval structure, the earlier parts of which date from the 12th century, and there are ruins of a collegiate church of St Everemont on an island in the river, and some traces of a castle built by Charles V. The port traffic in 1899 amounted to 41,185 tons. Population (1881), 7099; (1901), 9123.

**Cremation.**—A brief but interesting summary of the ancient usages among different nations in relation to the disposal of the body after death, and particularly to that by cremation, is given in the ninth edition of this work; and a few particulars are added of its introduction into the United Kingdom at an early period. It is the design of the present writer to continue the narrative to the present date. As there stated, Sir Henry Thompson was the first to introduce the practice, and to perform it experimentally on animals; advocating the procedure in an article which appeared in the *Contemporary Review* of January 1874, which excited considerable notice at home and abroad. He had seen Brunetti's results at the Vienna Exhibition in 1873, and his own were obtained in the manner described. At a very early date steps were taken to form an English Society to promote the practice of cremation. A declaration of its objects was drawn up and signed on 13th January 1874 by the following persons:—Shirley Brooks, William Eassie, Ernest Hart, the Rev. H. R. Haweis, G. H. Hawkins, John Cordy Jeaffreson, F. Lehmann, C. F. Lord, W. Shaen, A. Strahan, Henry Thompson, Major Vaughan, Rev. C. Voysey, and T. Spencer Wells; and they frequently met to consider the necessary steps in order to attain their object. The laws and regulations having been thoroughly discussed, the membership of the Society was constituted by an annual contribution for expenses, and a subscription to the following declaration:—

> "We disapprove the present custom of burying the dead, and desire to substitute some mode which shall rapidly resolve the body into its component elements by a process which cannot offend the living, and shall render the remains absolutely innocuous. Until some better method is devised, we desire to adopt that usually known as cremation."

Finally, on 29th April a meeting was held, a Council was formed, Sir H. Thompson was elected President and Chairman, an office he still held in 1901. Mr Eassie was at the same time elected secretary.[1]

In 1875 the following were added:—Mrs Rose Crawshay, Mr Higford Burr, Rev. J. Long, Mr W. Robinson, and the Rev. Brooke Lambert. Subsequently, and in order of date of appointment, followed the Rt. Hon. Lord Bramwell; Sir Chas. Cameron, M.P.; Dr Farquharson, M.P.; Sir Douglas Galton; Rt. Hon. Lord Playfair; Mr Martin Ridley Smith; Mr James A. Budgett; Mr Edmund Yates; Mr J. S. Fletcher; Mr J. C. Swinburne-Hanham; His Grace the Duke of Westminster (on Lord Bramwell's death); and Sir Arthur Arnold, L.C.C.

On account of difficulties and prejudices which cannot be further referred to here,[2] the Council was unable to purchase a freehold until 1878, when an acre was obtained at Woking, not far distant from the Cemetery. At this time the furnace employed by Professor Gorini of Lodi, Italy, appeared to be the best for working with on a small scale; and he was invited to visit this country to superintend its erection. This was completed in 1879, and the body of a horse was cremated rapidly and completely without any smoke or effluvia from the chimney. No sooner was this successful step taken than the President

[1] This was the first society formed in Europe for the promotion of cremation.

[2] For a full account of these, see *Modern Cremation: Its History and Practice to the Present Date*. By Sir H. Thompson, Bart., F.R.C.S., &c. Fourth edition. Smith & Elder, Waterloo Place, 1901.

received a communication from the Home Office, which resulted in a personal interview with the Home Secretary; the issue of which was that if the Society desired to avoid direct hostile action, an assurance must be given that no cremation should be attempted without leave first obtained from the Minister. This of course was given, no further building took place, and the Society's labours were confined to employing means to diffuse information on the subject. Sir Spencer Wells brought it before the annual meeting of the British Medical Association in 1880, when a petition to the Home Secretary for permission to adopt cremation was largely signed by the leading men in town and country, but without any immediate result. The next important development was an application to the Council in 1882, by Captain Hanham in Dorsetshire, to undertake the cremation of two deceased relatives who had left express instructions to that effect. The Home Secretary was applied to, and refused. The bodies were preserved, and Captain Hanham erected a crematorium on his estate, and the cremation took place there. He himself, dying a year later, was cremated also; in both cases the result was attained under the supervision of Mr J. C. Swinburne-Hanham, who succeeded Mr Eassie in 1888 as Secretary to the Society. The Government took no notice. But in 1883 a cremation was performed in Wales by a man on the body of his child, and legal proceedings were taken against him. Mr Justice Stephen, in February 1884, delivered his well-known judgment at the Assizes there, declaring cremation to be a legal procedure, provided no nuisance were caused thereby to others. The Council of the Society at once declared themselves absolved from their promise to the Home Office, and publicly offered to perform cremation, laying down strict rules for careful inquiry into the cause of death in every case. They stated that they were fully aware that the chief practical objection to cremation was that it removed traces of poison or violence which might have caused death. Declining to trust the very imperfect statement generally made respecting the cause of death in the ordinary death certificate (unless a coroner's inquest had been held), they adopted a system of very stringent inquiry, the result of which in each case was to be submitted to the President, to be investigated and approved by him before cremation could take place, with the right to decline or order an inquest if he thought proper; and this course has been followed ever since the first cremation.

It was on 26th March 1885 that the first cremation took place, the subject being a lady.[1] In 1888 it became necessary, nearly 100 bodies having been by this date cremated, to build a large hall for religious service, as well as waiting-rooms, in connexion with the crematorium. The Dukes of Bedford and Westminster headed the appeal for funds, each with £105. The former especially took great interest in the progress of the Society, and offered to furnish further donations to any extent necessary. During the next two years he generously defrayed costs to the amount of £3500, and built a smaller crematorium adjacent for himself and family. The latter building was first used on 18th January 1891, a few days after the death of His Grace (the ninth duke of Bedford). The number of cremations slowly increased year by year, and the total at the end of 1900 was 1824. Many of these were persons of distinction—by rank, or by attainments in art, literature, and science, or in public life.

The Council next turned their attention to the need for a national system of death certification, to be enforced by law as an essential and much needed reform in connexion with cremation. On 6th January 1893 the Duke of Westminster introduced a deputation to the Secretary of State for the Home Department, Mr Asquith, and the President of the Cremation Society opened the case, showing that no less than 7 per cent. of the burials in England took place without any certificate, while in some districts it was far greater. In consequence of this the Home Secretary appointed a Select Committee of the House of Commons, which was presided over by Sir Walter Foster, of the Local Government Board, "to inquire into the sufficiency of the existing law as to the disposal of the dead . . . and especially for detecting the causes of death due to poison, violence, and criminal neglect." After a prolonged inquiry and careful consideration of the evidence, a full report and conclusions drawn therefrom were unanimously agreed to, and published as a blue-book in the autumn of 1893.[2]

The following conclusions are quoted from this volume :—Page iii. "So far as affording a record of the true cause of death and the detection of it in cases where death may have been due to violence, poison, or where criminal neglect is concerned, the class of certified deaths leaves much to be desired." Page iv. Certification is extremely important as a deterrent of crime, and numerous proofs are given at length in support of the statement. . . . "Contrast this class with that of uncertified deaths, when the result is such as to force upon your Committee the conviction that vastly more deaths occur annually from foul play and criminal neglect than the law recognizes." Page viii. Great uncertainty in resorting to the coroner's court, and want of system in connexion with the practice of it, are affirmed to exist. Page x. It is stated that the opportunity for perpetrating crime is great in the considerable class of uncertified cases . . . "in short, the existing procedure plays into the hands of the criminal classes." "Your Committee are much impressed with the serious possibilities implied in a system which permits death and burial to take place without the production of satisfactory medical evidence of the cause of death." Page xii. "Your Committee have arrived at the conclusion that the appointment of medical officials, who should investigate all cases of death which are not certified by a medical practitioner in attendance, is a proposal which deserves their support."

In considering cremation, the Committee reported as follows :—Page xxii. "Your Committee are of opinion that there is only one question in connexion with this method of disposing of a dead body to which it is necessary for them to refer. That question is the supposed danger to the community arising from the fact that with the destruction of the body the possibility of obtaining evidence of the cause of death by *post-mortem* examination also disappears." The mode of proceeding adopted by the Cremation Society of England having been described, "your Committee are of opinion that with the precautions adopted in connexion with cremation, as carried out by the Cremation Society, there is little probability that cases of crime would escape detection, but inasmuch as these precautions are purely voluntary, your Committee consider that in the interests of public safety such regulations should be enforced by law."

After this, it could only be a question of time before the admitted demands for official inquiry were enforced by law in every case of death; when that is done, the general employment of cremation may safely follow. In August 1894 the President of the Society laid the results of the Select Committee before the British Medical Association at Bristol, and a unanimous vote was obtained in favour of the suggestions made by it. In November a second deputation waited on Mr Asquith, in which the President of the Society begged him to carry out the system recommended. The Home Secretary replied that the business belonged to the Department of the Local Government Board, and that it was already dealing with the question and bringing it to a satisfactory solution. Soon afterwards, however, the Government changed, other questions became pressing, and further consideration of the subject was postponed.

It is most desirable to put in force by Act of Parliament the recommendations of the Select Committee before mentioned. The

[1] *Times*, 27th March 1885.

[2] *Reports on Death Certification*, 1893. Eyre & Spottiswoode, London (373, 472).

chief provisions have been carefully considered by the Council of the Society, and the regulations necessary for registration of death and the disposal of the dead may be outlined as follows:— 1. That no body should be buried, cremated, or otherwise disposed of without a medical certificate of death signed, after personal knowledge and observation, or by information obtained after investigation made by a qualified medical officer appointed for the purpose. 2. A qualified medical man should be appointed as official certifier in every parish, or district of neighbouring parishes, his duty being to inquire into all cases of death and report the cause in writing, together with such other details as may be deemed necessary. This would naturally fall within the duties of the medical officer of health for the district, and registration should be made at his office. 3. If the circumstances of death obviously demand a coroner's inquest, the case should be transferred to his court and the cause determined, with or without autopsy. If there appears to be no ground for holding an inquest, and autopsy be necessary to the furnishing of a certificate, the official certifier should make it, and state the result in his report. 4. No person or company should be henceforth permitted to construct or use an apparatus for cremating human bodies without licence from the Local Government Board or other authority. 5. No crematory should be so employed unless the site, construction, and system of management have been approved after survey by an officer appointed by Government for the purpose. But the licence to construct or use a crematory should not be withheld if guarantees are given that the conditions required are or will be complied with. All such crematories to be subject at all times to inspection by an officer appointed by the Government. 6. The burning of a human body, otherwise than in an officially recognized crematory, should be illegal, and punishable by penalty. 7. No human body should be cremated unless the official examiner added the words "Cremation permitted." This he should be bound to do if, after due inquiry, he can certify that the deceased has died from natural causes, and not from ill-treatment, poison, or violence.

Undoubtedly in populous communities and in crowded districts the burial of dead bodies is liable to be a source of danger to the living. As early as 1840 a Commission had been appointed, including some of the earliest authorities on sanitary science,—namely, Drs Southwood Smith, Chadwick, Milroy, Sutherland, Waller Lewis, and others,—to conduct a searching inquiry into the state of the burial-grounds of London and large provincial towns. By the report[1] the existence of such a danger was strikingly demonstrated, and intramural interments were in consequence made illegal. The advocates of burial then declared that interment in certain light soils would safely and efficiently decompose the putrefying elements which begin to be developed the moment death takes place, and which rapidly become dangerous to the living, still more so in the case of deaths from contagious disease. But these light dry soils and elevated spots are precisely those best adapted for human habitation; to say nothing of their value for food-production. Granted the efficiency of such burial, it only effects in the course of a few years what exposure to a high temperature accomplishes with absolute safety in an hour. In a densely populated country the struggle between the claims of the dead and the living to occupy the choicest sites becomes a serious matter. All decaying animal remains give off effluvia—gases—which are transferred through the medium of the atmosphere to become converted into vegetable growth of some kind—trees, crops, garden produce, grass, &c. Every plant absorbs these gases by its leaves, each one of which is provided with hundreds of stomata—open mouths—by which they fix or utilize the carbon to form woody fibre, and give off free oxygen to the atmosphere. Thus it is that the air we breathe is kept pure by the constant interaction between the animal and vegetable kingdoms. It may be taken as certain that the gaseous products arising from a cremated body—amounting, although invisible, to no less than 97 per cent. of its weight, 3 per cent. only remaining as solids, in the form of a pure white ash—become in the course of a few hours integral and active elements in some form of vegetable life. The result of this reasoning has been that, by slow degrees, crematoria have been constructed at many of the populous cities in Great Britain and abroad. In Manchester a large one was opened in 1892, in Glasgow in 1894, in Liverpool in 1896, in Hull in 1899. In Birmingham another is in progress of formation.

[1] *A Special Inquiry into the Practice of Interment in Towns*, by Edwin Chadwick (London, 1843), is replete with evidence, and should be read by those who desire to pursue the inquiry further.

The subject of employing cremation for the bodies of those who die of contagious disease is a most important one. Sir H. Thompson advocated this course in a paper read before the International Congress of Hygiene held in London in 1891; and a resolution strongly approving the practice was carried unanimously at a large meeting of experts and medical officers of health. Such diseases are small-pox, scarlet fever, diphtheria, consumption, malignant cholera, enteric, relapsing, and puerperal fevers, the annual number of deaths from which in the United Kingdom is upwards of 80,000. Complete disinfection takes place by means of the high temperature to which the body is exposed. Heated air suffices, and the chamber of a Siemens regenerative gas-furnace, where no flame enters, is the most perfect form for accomplishing the process. It will probably, at no distant period, supersede the furnaces now employed. At the present day it is compulsory to report any case in the foregoing list, whenever it occurs, to the medical officer of health for the district; and it is customary to disinfect the rooms themselves, as well as the clothes and furniture used by the patient if the case be fatal; but the body, which is the source and origin of the evil, and is itself loaded with the germs of a specific poison, is left to the chances which attach to its preservation in that condition, when buried in a fit or unfit soil or situation.

The process of preparing a body for cremation requires a brief notice. The plan generally adopted is to place it (in the usual shroud) in a light pine shell, discarding all heavy oak or other coffin, and to introduce it into the furnace in that manner. For the purpose of transit such a shell is convenient and appropriate; but it is best to discard the linen shroud—the combustion of which, together with the shell, produces a quantity of black charcoal, which has subsequently to be separated, not without some trouble, from the white ashes of the body—in favour of one of a stout woollen material; this, being an animal product, is destroyed and dissipated by cremation, and is so made that the body may be easily cremated without the shell. A sheet of flannel is provided, say 10 feet by 5 or 6 feet for an adult of average size, in which the body is placed; the sides of the sheet are then to be folded across the body, one overlapping the other, so as to cover it entirely. Thus the folded ends of the sheet will extend some 2 feet or so above and below the head and feet of the body respectively. Above each of these points a piece of stout wide strong tape or web should be firmly tied round the folded sheet, and in at least two places round the covered body also, so as to maintain the sheet *in situ*. These ends are then turned over when the body has been placed in the shell, before the lid is adjusted for removal. Immediately before the act of cremation commences, the shell should be opened, the body be carefully and reverently lifted out by a bearer at each end of the sheet, a third supporting the centre, and be placed on the frame which enters the crematorium.

The following statistics show the history of modern cremation and its progress at home and abroad to the present date:—

*Foreign Countries.*—The first experiment in Italy was made by Brunetti in 1869, his second and third in 1870. Gorini and Polli published their first cases in 1872. Brunetti exhibited his at Vienna in 1873. All were performed in the open air. The next in Europe was a single case at Breslau in 1874. Soon after, an English lady was cremated in a closed apparatus (Siemens) at Dresden. The next cremation in a closed receptacle took place at Milan in 1876. In the same year a Cremation Society was formed, a handsome building was erected, and two Gorini furnaces were at work in 1880. In 1899 the total number of cremations was 1355. Other crematoria were subsequently erected at Lodi, Cremona, Brescia, Bologna, Varese, Padua, and Venice. At Bologna the total

cremations numbered 155 up to December 31, 1900. At Venice the total cremations numbered 45 in May 1899. One crematorium began in Rome in 1883, and the cremations numbered 800 up to May 1899. At the present time 28 crematoria exist in Italy.

In Germany the first crematorium was erected at Gotha; it began in 1879, and the total cremations in December 31, 1900, numbered 2468. At Ohlsdorf, Hamburg, the crematorium began in November 1892, and the total cremations up to December 31, 1900, numbered 646. At Heidelburg the crematorium started in 1891, and the total cremations up to November 28, 1900, numbered 895. A crematorium started working at Offenbach on December 13, 1899, and at the end of its first year (December 13, 1900) had cremated 113 bodies. Throughout the German Empire there are forty societies for promoting cremation, numbering about 40,000 members.

Other societies now exist in Denmark, Holland, Belgium, Sweden, Norway, and Switzerland. At the crematorium recently constructed at Copenhagen 28 bodies were cremated in 1899, the same in 1900; the total being 56. The Stockholm crematorium began in October 1887, and the total cremations up to May 1899 numbered 495. The Gothenburg crematorium (also in Sweden) began in January 1890, and the total cremations up to May 1899 was 120.

In Paris a Cremation Society was founded in 1880, and in 1886–87 a large crematorium was constructed by the Municipal Council at Père Lachaise, containing three Gorini furnaces. It was first used in October 1887 for two men who died of small-pox. The demand became large; an improved furnace was soon devised, the unclaimed bodies at the hospitals and the remains at the dissecting rooms being cremated there, besides a large number of embryos. In 1890 the total number, including the last-named class, exceeded 3000; in 1895, 4000; numbering 4554 at the end of 1899; and the number for the year 1900 was rather larger. The total number of incinerations in private life exceeds the previous record, being, up to December 31, 1900, 197; but the employment of cremation for the purposes named has deterred a resort to it by many. Had a separate establishment been organized for the public, its success would have been greater; the error is now obvious and may be rectified soon, for a magnificent edifice is in course of construction by the municipality of Paris for the conservation of the ashes, &c., which will form a larger and more imposing columbarium than has yet been seen. Lastly, the construction of crematoria in all the great provincial centres of France—Lyons, Lille, Rheims, Nice, Marseilles, Toulouse, and Bordeaux—is being completed or is commencing. At Rouen it is already in operation with good results, the low damp soil there being unfit for burial.[1]

In Buenos Ayres, since 1844, the bodies of all persons dying of contagious disease are cremated, and there is also a separate establishment for the use of the public.

At Tokio in Japan no less than twenty-two crematoria exist, and about an equal number of cremations and burials in earth take place.

*United Kingdom.*—The following is the report from the crematorium at Woking for each year, commencing with the first in 1885 and concluding with that ending December 31, 1900.

*Cremations at Woking.*

| Year. | Number. | Year. | Number. |
|---|---|---|---|
| 1885 | 3 | 1894 | 125 |
| 1886 | 10 | 1895 | 150 |
| 1887 | 13 | 1896 | 137 |
| 1888 | 28 | 1897 | 173 |
| 1889 | 46 | 1898 | 240 |
| 1890 | 54 | 1899 | 240 |
| 1891 | 99 | 1900 | 301 |
| 1892 | 104 | | |
| 1893 | 101 | Total | 1824 |

The Manchester crematorium began in 1892, and the total cremations to December 31, 1900, numbered 475. The Glasgow crematorium began in 1895, and the total cremations up to December 31, 1900, numbered 75. The Liverpool crematorium began in 1896, and the total cremations up to December 31, 1900, numbered 102. The Hull crematorium was opened on January 2, 1901. It is the first crematorium erected in England under municipal authority. Seven cremations took place within a month of its opening. The Birmingham crematorium is not yet in operation. The capital is subscribed, but a proper site has not yet been met with.

[1] The writer is indebted for the history of cremation in France and its departments to the *Bulletin de la Soc pour la Propagation de l'Incinération*, Paris, by M. Georges Salomon, secretary from its foundation in 1880 up to the end of 1900; and also for the reports from South America and Japan. The present writer has visited Père Lachaise several times, and the above report is partly based on his personal observation.

The Cremation Society of England has been long endeavouring to obtain a site on which to establish a crematorium within convenient driving distance of Central London; and in December 1899 a company was formed for the purpose, its title being "The London Cremation Company Ltd."

The only crematorium at present available to the inhabitants of London is that at Woking, the property of, and managed by, the Cremation Society of England; but a freehold site, 12 acres in extent, has been purchased about 5 miles distant from the Marble Arch, surrounded by open country, and on one of the best main roads north of London, and here it is intended to erect crematoria on the newest and the most approved principle, with a chapel, waiting-rooms, and attendants' lodges, together with private and public columbaria for the reception of cinerary urns. The land not so occupied will be laid out as a garden, with lawns, trees, and shrubs, becoming a place of increasing interest and beauty from year to year: where ample space will be afforded for the erection of monuments, and provision made for the interment of ashes for those who prefer it.

*United States.*—There are twenty-five crematoria in the United States. At Fresh Pond, New York, the first crematorium was erected in 1885, and the total number of cremations to December 31, 1900, was 3903. At Buffalo, N.Y., the first cremation took place in 1885, and the total number up to December 31, 1900, was 484. At Troy (Earl Crematorium), N.Y., the first cremation took place in 1890, and the total number up to December 31, 1900, was 146. At Swinburne Island, N.Y., cremations commenced in 1890, total to 1898 being 106. At Waterville, N.Y., cremations commenced in 1893, total to December 31, 1900, being 38. At St Louis, Missouri, cremations commenced in 1888, total to December 31, 1900, being 1054. At Philadelphia, Penn., cremations commenced in 1888, total to December 31, 1900, being 914. At San Francisco, Cal. ("Odd Fellows"), commenced in 1895, total to December 31, 1900, being 1535. At San Francisco, Cal. ("Cypress Lawn"), commenced in 1893, total to December 31, 1900, being 632. At Los Angelos, Cal., commenced in 1888, total to 1898 being 352. At Boston, Mass., commenced in 1893, total to December 31, 1900, being 1057. At Cincinnati, Ohio, commenced in 1887, total to December 31, 1900, being 647. At Chicago, commenced in 1893, total to December 31, 1900, being 695. At Detroit, Michigan, commenced in 1887, total to December 31, 1900, being 371. At Pittsburg, Penn., commenced in 1886, total to December 31, 1900, being 216. At Baltimore, commenced in 1889, total to December 31, 1900, being 180. At Lancaster, Penn., commenced in 1884, total to December 31, 1900, being 95. At Davenport, Iowa, commenced in 1891, total to December 31, 1900, being 134. At Milwaukee, commenced in 1896, total to October 1900 being 170. At Washington, commenced in 1897, total to December 31, 1900, being 109. The Le Moyne (Washington) Crematory, the first in the United States, was erected by Dr F. Julius Le Moyne in 1876 for private use. The first cremation was that of the Baron de Palin of New York, December 6, 1876. Dr F. Julius Le Moyne died October 1879, and his remains were cremated in his own crematory. Total number cremations since, to February 1901, being 42. At Pasadena, Cal., commenced in 1895, total to end of 1898 being 55. At St Paul, Minn., commenced in 1897, total to December 31, 1900, being 55. At Fort Wayne, Ind., commenced in 1897, total to December 31, 1900, being 14. From the remaining crematorium at Middletown, Conn., statistics have not been received.

The sum total of the above incinerations at the twenty-five crematoria in America amounts to 13,004 up to December 31, 1900.

(H. TH.)

**Cremer, Jakobus Jan** (1837–1880), Dutch novelist, born at Arnhem, September 1837, started life as a painter, but soon exchanged the brush for the pen. The great success of his first novelettes (*Betuwsche Novellen* and *Overbetuwsche Novellen*), published about 1855—reprinted many times since, and translated into German and French—showed Cremer the wisdom of his new departure. These short stories of Dutch provincial life are written in the quaint dialect of the Betuwe, the large flat Gelderland island, formed by the Rhine, the name recalling the presumed earliest inhabitants, the Batavi. Cremer is strongest in his delineation of character. His picturesque humour, coming out, perhaps, most forcibly in his numerous readings of the Betuwe novelettes, soon procured him the name of the "Dutch Fritz Reuter." In his later novels Cremer abandons both the language and the slight love-stories of the Betuwe, depicting the Dutch life of other centres in the national tongue. The

principal are: *Anna Rooze* (1867), *Dokter Helmond en zijn Vrouw* (*Dr H. and his Wife*, 1870), *Hanna de Freule* (*The Honourable Miss Hannah*, 1873), *Daniel Sils*, &c. Cremer was less successful as a playwright, and his two comedies, *Peasant and Nobleman* and *Emma Bertholt*, did not enhance his fame; nor did a volume of poems, published in 1873. He died at The Hague in June 1880. His collected novels have appeared at Leyden. An English novel, founded by Albert Vandam upon *Anna Rooze*, considered by many his best work, was published in London (1877, 3 vols.) under the title of *An Everyday Heroine*. (H. TI.)

**Cremona**, a fortified town and episcopal see of Lombardy, Italy, capital of the province Cremona, on the left bank of the Po, 51 miles by rail south-east from Milan, an important railway junction in the middle of North Italy. Amongst the public buildings should be particularly mentioned the Renaissance churches of St Sigismund (begun in 1463) and St Peter (1549), the baptistery (*circa* 900, but rebuilt in 1167), the Palace of the Jurisconsults (1292), and the Ala-Ponzone Museum, containing works of the native school of painters, and archæological collections. There are also statues to Garibaldi, Victor Emmanuel, and the musician Ponchielli (1893). Cremona has two technical schools and a school of singing. Its manufactures embrace the rearing of silkworms and silk-throwing, with ironworks and foundries. Population (1881), 31,930; (1901), 37,661.

**Cremona, Luigi** (1830——), Italian mathematician, was born at Pavia 7th December 1830. In 1848, when Milan and Venice rose against Austria, Cremona, then only a lad of seventeen, joined the ranks of the Italian volunteers, and remained with them, fighting on behalf of his country's freedom, till, in 1849, the capitulation of Venice put an end to the hopeless campaign. He then returned to Pavia, where he pursued his studies at the university under the distinguished mathematician Brioschi, and determined to seek a career as teacher of mathematics. His first appointment was as elementary mathematical master at the Gymnasium and Lyceum of Cremona, and he afterwards obtained a similar post at Milan. In 1860 he was appointed to the professorship of Higher Geometry at the University of Bologna, and in 1866 to that of Higher Geometry and Graphical Statics at the Higher Technical College of Milan. In this same year he competed for the Steiner Prize of the Berlin Academy, with a treatise entitled "Memoria sulle superficie di terzo ordine," and shared the award with Professor Sturm. Two years later the same prize was conferred on him without competition. In 1873 he was called to Rome to organize the College of Engineering, and was also appointed Professor of Higher Mathematics at the university. Cremona's reputation had now become European, and in 1879 he was elected a corresponding member of the Royal Society. In the same year he was made a senator of the Kingdom of Italy. As early as 1856 Cremona had begun to contribute to the *Annali di Scienze matematiche e fisiche*, and to the *Annali di Matematica*, of which he became afterwards joint editor. Papers by him have appeared in the mathematical journals of Italy, France, Germany, and England, and he has published several important works, many of which have been translated into other languages. His manual on *Graphical Statics* and his *Elements of Projective Geometry* have been published in English by the Clarendon Press. His life has been devoted to the study of higher geometry and reforming the more advanced mathematical teaching of Italy. He is a follower of Steiner, preferring synthetic to analytic methods. In his *Introduction to a Geometrical Theory of Plane Curves* he develops by a uniform method many new results, and proves synthetically all important results hitherto reached by analysis. The theory of the transformation of curves, and of the correspondence of points on curves, was extended by him to three dimensions. He has devoted special attention to ruled surfaces, surfaces of the second order, space-curves of the third order, and the general theory of surfaces.

**Creston**, capital of Union county, Iowa, U.S.A., on the high prairie (whence its name), at an altitude of 1312 feet. It is at the intersection of two branches of the Chicago, Burlington, and Quincy Railways. Population (1880), 5081; (1900), 7752.

**Creswick**, a borough of Victoria, Australia, in the county of Talbot, on the Tullaroop Creek, 85½ miles by rail north-west of Melbourne, and 11 miles north of Ballarat. Much of the surrounding district is fertile and well timbered. The quartz and alluvial gold mines of the district are important, employing about 1300 persons. Population (1881), 3731; (1900), about 4700.

**Crete.**—During the past half-century the affairs of Crete have repeatedly occupied the attention of Europe. Owing to the existence of a strong Mussulman minority among its inhabitants, the warlike character of the natives, and the mountainous configuration of the country, which enabled a portion of the Christian population to maintain itself in a state of partial independence, the island has constantly been the scene of prolonged and sanguinary struggles in which the numerical superiority of the Christians was counterbalanced by the aid rendered to the Moslems by the Ottoman troops. This unhappy state of affairs was aggravated and perpetuated by the intrigues set on foot at Constantinople against successive governors of the island, the conflicts between the Palace and the Porte, the duplicity of the Turkish authorities, the dissensions of the representatives of the Great Powers, the machinations of Greek agitators, the rivalry of Cretan politicians, and prolonged financial mismanagement. A long series of insurrections—those of 1821, 1833, 1841, 1858, 1866-1868, 1878, 1889, and 1896 may be especially mentioned—culminated in the general rebellion of 1897, which led to the interference of Greece, the intervention of the Great Powers, the expulsion of the Turkish authorities, and the establishment of an autonomous Cretan government under the suzerainty of the sultan. According to the new autonomous constitution, the supreme power is vested in Prince George of Greece, acting as high commissioner of the protecting Powers. The authority thus conferred is confided exclusively to the present high commissioner, and is liable to modification by law in the case of his successor. The prince is irresponsible, but his decrees, except in certain specified cases, must be countersigned by a member of his Council. He convokes, prorogues, and dissolves the Chamber, sanctions laws, exercises the right of pardon in case of political offences, represents the island in its foreign relations, and is chief of its military forces. The Chamber (βουλή), which is elected in the proportion of one deputy to every 5000 inhabitants, meets for a session of two months every two years. Ten of its members are nominated by the prince. A new election is held before each session, and when the Chamber assembles a budget for a period of two years is submitted. The Chamber exercises a complete financial control, and no taxes can be imposed without its consent. The prince is aided in the administration by a Cabinet of five members, styled "councillors" (σύμβουλοι), who superintend respectively the departments of justice, finance, education, public security, and the interior. The councillors, who are nominated and dismissed by the prince, are

responsible to the Chamber, which may impeach them before a special tribunal for any illegal act or neglect of duty. Large exceptional legislative and administrative powers were accorded to the prince at the opening of his rule. In general the Cretan constitution is characterized by a conservative spirit, and contrasts with the ultra-democratic systems established in Greece and the Balkan States. A further point of difference is the more liberal payment of public functionaries in Crete. For administrative purposes the departmental divisions existing under the Turkish Government have been retained. There are 5 *nomoi* or prefectures (formerly *sanjaks*) each under a prefect (*νομάρχης*), and 23 eparchies (formerly kazas) each under a sub-prefect (*ἔπαρχος*). All these functionaries are nominated by the prince. The prefects are assisted by departmental councils. The system of municipal and communal government remains practically unchanged. The island is divided into 86 communes, each with a mayor, an assistant-mayor, and a communal council. The mayors and their assistants were formerly elected; they are now appointed by the high commissioner, who also for the present nominates the members of the communal councils. The councils assess within certain limits the communal taxes, maintain roads, bridges, &c., and generally superintend local affairs. Public order is maintained by a force of gendarmery (*χωροφυλακή*) organized and at present commanded by 110 Italian officers, who in course of time will be succeeded by natives. The proposed strength was 1400 men, but this number has been reduced to 1246. The expenditure for the maintenance of this force forms the heaviest item in the budget. The constitution authorizes the formation of a militia (*πολιτοφυλακή*) to be enrolled by conscription, but in existing circumstances the embodiment of this force seems unnecessary. The administration of justice is on the French model. A supreme court of appeal, which also discharges the functions of a court of cassation, sits at Canea. There are two assize courts at Canea and Candia respectively with jurisdiction in regard to serious offences (*κακουργήματα*). Minor offences (*πλημμελήματα*) and civil causes are tried by courts of first instance in each of the five departments. There are 26 justices of peace, to whose decision are referred slight contraventions of the law (*πταίσματα*) and civil causes in which the amount claimed is below 600 francs. These functionaries also hold monthly sessions in the various communes. The judges are chosen without regard to religious belief, and precautions have been taken to render them independent of political parties. They are appointed, promoted, transferred, or removed by order of the council of justice, a body composed of the five highest judicial dignitaries, sitting at Canea. An order for the removal of a judge must be based upon a conviction for some specified offence before a court of law. The jury system has not been introduced. The Greek penal code has been adopted with some modifications. The Ottoman civil code is maintained for the present, but it is proposed to establish a code recently drawn up by Greek jurists which is mainly based on Italian and Saxon law. The Mussulman cadis retain their jurisdiction in regard to religious affairs, marriage, divorce, the wardship of minors and inheritance.

*Finance.*—The budget estimates for the year 1900, the first which had been made up for a complete year under the new autonomous government, were as given below. In addition to the regular revenues inscribed in the budget, a sum estimated at 3,700,000 dr. approximately remained available, derived from the issue of a new coinage and other exceptional sources. The four protecting Powers further advanced 1,000,000 fr. each to defray the initial expenses of the High Commissioner's Government. It was proposed to expend considerable sums on roadmaking

and public works. The Cretans are at present more lightly taxed than any people in Europe. The tithe has been replaced by an export tax on agricultural produce levied at the custom-houses, and the smaller peasant proprietors and shepherds of the mountainous districts are practically exempt from any contribution to the State. The communal tax does not exceed on the average 2 fr. annually for each family. The poorer communes are aided by a State subvention. Notwithstanding the havoc wrought during repeated insurrections, the impoverishment of the peasants, the desolation of the districts formerly inhabited by the Moslem agricultural population, and the drain of gold resulting from the sale of Moslem lands and emigration of the former proprietors, the financial prospects of the island were favourable, and a rapid recovery of prosperity was anticipated.

*Production and Industries.*—Owing to the volcanic nature of its soil, Crete is probably rich in minerals. Recent experiments lead to the conclusion that iron, lead, manganese, lignite, and sulphur exist in considerable abundance. Copper and zinc have also been found. A large number of applications for mining concessions have been received since the establishment of the autonomous government. The principal wealth of the island is derived from its olive groves; notwithstanding the destruction of many thousands of trees during each successive insurrection, the production is apparently undiminished, and will probably increase very considerably owing to the planting of young trees and the improved methods of cultivation which the Government is endeavouring to promote. The orange and lemon groves have also suffered considerably, but new varieties of the orange tree are now being introduced, and an impulse will be given to the export trade in this fruit by the removal of the restriction on its importation into Greece. Agriculture is still in a primitive condition; notwithstanding the fertility of the arable land the supply of cereals is far below the requirements of the population. A great portion of the central plain of Monofatsi, the principal grain-producing district, is lying fallow owing to the exodus of the Moslem peasantry. The cultivation of silk cocoons, formerly a flourishing industry, has greatly declined in recent years, but efforts are now being made to revive it. There are few manufactures. Soap is produced at fifteen factories in the principal towns, and there are two distilleries of cognac at Candia.

*Commerce.*—The commerce of the island was expected to develop rapidly under the new system of government. The total value of the exports for the year 1899 was 8,040,912 drachmæ. The principal exports were olive oil, value 4,361,029 dr.; soap, value 320,806; and hides, value 208,170 dr. Oranges, lemons, almonds, and valonia are exported in considerable quantities. The countries which accept the largest share of Cretan produce are Turkey, England, Egypt, Austria, and Russia, in the order named. The total value of imports in 1899 was 15,842,743 dr. Imports from Turkey are valued at 5,865,350 dr., from Greece at 5,147,193 dr., from Austria at 2,030,826 dr., from Roumania at 1,051,145 dr., from Egypt at 655,548 dr., from Italy at 463,833 dr., from France at 180,397 dr., from England at 149,986 dr., from Bulgaria at 107,503 dr. Cereals are imported from the Black Sea and Danubian ports, ready-made clothing from Austria and Germany, articles of luxury from Austria and France, and cotton textiles from England. Imports are charged 8 per cent., exports 1 per cent. *ad valorem* duty. According to a law published in 1899, Turkish merchandise is subjected to the same rates as that of foreign nations.

*Population.*—According to the census taken in 1881, the complete publication of which was interdicted by the Turkish authorities, the population of the island was 279,165, or 35·78 to the square kilometre. Of this total, 141,602 were males, 137,563 females; 33,173 were literate, 242,114 illiterate; 205,010 were orthodox Christians, 73,234 Moslems, and 921 of other

religious persuasions. The Moslem element predominated in the principal towns, of which the population was—Candia, 21,368; Canea, 13,812; Retimo, 9274. According to the census taken in June 1900, the population of the island was 301,273, the Christians having increased to 267,266, while the Moslems had diminished to 33,281. The population of Candia was 22,501; of Canea, 20,972; of Retimo, 9311.

*Archæological research: early Cretan civilization.*

Lying midway between three continents, Crete became a natural stepping-stone for the passage of early culture from the east and south to the west and north. Under the myths of Minos and Dædalos the Greeks proclaimed their indebtedness to Cretan sources in the domains of law and art. Recent researches have illustrated the truth of these traditions in many interesting ways. The ancient remains which abound throughout the island show conclusively that the days of its greatest civilization lie behind the prehistoric period. Even the remotest nooks are studded with the ruins of Cyclopean strongholds and tower-houses, and here and there, as at Goulas in the east and Hyrtakina in the west, a complete acropolis is found. Goulas especially, rising in a succession of huge terraces, presents a mass of prehistoric masonry hardly paralleled elsewhere. The ancient stone vases and engraved seals found on these sites supply definite traces of a contact with Egypt going back to the period of the 12th dynasty, and dating from at least the latter half of the third millennium B.C. An intermediate period follows, characterized by the appearance of painted clay vases of an indigenous kind, first discovered in a votive cave at Kamáres, on the southern slopes of Mount Ida, and subsequently in greater abundance at Knossós. But the most brilliant period of prehistoric Cretan civilization corresponds with the great age of Mycenæ (the 14th and 15th centuries B.C.), and the contents of a palace of this epoch, recently excavated on the acropolis of Knossós by Mr A. J. Evans, show that in sculpture and fresco-painting the artists of Minoan Crete equalled, if they did not surpass, those of the contemporary Peloponnesos. Of all the evidences of this early civilization now brought to light the most remarkable is the discovery of an elaborate system of writing. A series of signs, both of the linear and more pictographic class, had already been observed on early seal-stones, and other objects. In the palace at Knossós, however, have been found a large number of clay tablets, analogous in many respects to the cuneiform tablets of Babylonia, but inscribed with the indigenous Cretan character. They are apparently palace archives and lists of horses, chariots, and stores in the royal stables and arsenal. To this brilliant Mycenæan age succeeds the period of the Dorian emigration, characterized by the "geometric" type of art. The decline of civilization is marked by a falling off in artistic production, but to a less extent than on the Greek mainland, a certain continuity of ancient traditions being maintained. By about the 8th century B.C. there is a manifest artistic revival, best illustrated by some of the reliefs on the bronze shields discovered in the great cave of Zeus on Mount Ida, in which the native Cretan handiwork more than holds its own beside imported Cypro-Phœnician examples. During the so-called archaic period of Greek art, Crete, the ancient home of letters, shows itself especially rich in epigraphic materials. The great inscription of Gortyna, discovered by Halbherr and Fabricius, is the most important monument of early law hitherto brought to light in any part of the Greek world. A very interesting inscription found at Præsos in eastern Crete shows that the language of the pre-Hellenic population, the Eteocretes of Homer, survived in that region till at least the beginning of the 5th century B.C. Of early Greek buildings in Crete, the most remarkable yet discovered is the Pythion at Gortyna. Exploration in progress at Axos, where important bronze reliefs have been found, and elsewhere, promises to add to our knowledge of classical art in Crete: meanwhile it is best represented by a very interesting series of coin-types, which show a certain marked originality and picturesqueness of design, but at the same time give evidence of repeated lapses into barbarism, resulting from the internecine feuds of the various cities and their isolation from the rest of the Greek world. (See also MYCENÆAN CIVILIZATION.)

*Recent History.*—Cretan constitutional history may be said to date from 1868, when, after the suppression of an insurrection which had extended over three years, the Turkish Government consented to grant a certain measure of autonomy to the island. The privileges now accorded were embodied in what is known as the Organic Statute, an instrument which eventually obtained a somewhat wider importance, being proposed by Article XXIII. of the Berlin Treaty as a basis of reforms to be introduced in other parts of the Ottoman empire. Various privileges already acquired by the Christian population were confirmed; a General Council, or representative body, was brought into existence, composed of deputies from every district in the island; mixed tribunals were introduced, together with a highly elaborate administrative system, under which all the more important functionaries, Christian and Mussulman, were provided with an assessor of the opposite creed. The new constitution, however, proved costly and unworkable, and failed to satisfy either section of the population. The Christians were ready for another outbreak, when, in 1878, the Greek Government, finding Hellenic aspirations ignored by the Treaty of San Stefano, gave the signal for agitation in the island. During the insurrection which followed the usual barbarities were committed on both sides; the Christians betook themselves to the mountains and the Mussulman peasants crowded into the fortified towns. Eventually the Cretan chiefs invoked the mediation of England, which Turkey, exhausted by her struggle with Russia, was ready to accept, and the convention known as the Pact of Halepa was drawn up in 1878 under the auspices of Mr Sandwith, the British Consul, and Adossides Pasha, both of whom enjoyed the confidence of the Cretan population.

*Pact of Halepa.*

The privileges conferred by the Organic Statute were confirmed; the cumbersome and extravagant judicial and administrative systems were maintained; the judges were declared independent of the executive, and an Assembly composed of forty-nine Christian and thirty-one Mussulman deputies took the place of the former General Council. A parliamentary regime was thus inaugurated, and party warfare for a time took the place of the old religious antagonism, the Moslems attaching themselves to one or other of the political factions which now made their appearance among the Christians. The material interests of the island were neglected in the scramble for place and power; the finances fell into disorder, and the party which came off worst in the struggle systematically intrigued against the Governor-General of the day and conspired with his enemies at Constantinople. A crisis came about in 1889, when the "Conservative" leaders, finding themselves in a minority in the Chamber, took up arms and withdrew to the mountains. Though the outbreak was unconnected with the religious feud, the latent fanaticism of both creeds was soon aroused, and the island once more became a scene of pillage and devastation. Unlike the two preceding movements, the insurrection of 1889 resulted unfavourably for the Christians. The Porte, having induced the

Greek Government to persuade the insurgents not to oppose the occupation of several strategic posts, despatched a military governor to the island, proclaimed martial law, and issued a firman abrogating many important provisions of the Halepa Pact. The mode of election to the Assembly was altered, the number of its members reduced, and the customs revenue, which had hitherto been shared with the island, was appropriated by the Turkish Treasury. The firman was undoubtedly illegal, as it violated a convention possessing a quasi-international sanction, but the Christians were unable to resist, and the Powers abstained from intervention. The elections held under the new system proved a failure, the Christains refusing to go to the polls, and for the next five years Crete was governed absolutely by a succession of Mahommedan Valis. The situation went from bad to worse, the deficit in the budget increased, the gendarmery, which received no pay, became insubordinate, and crime multiplied. In 1894 the Porte, at the instance of the Powers, nominated a Christian, Karatheodory Pasha, to the governorship, and the Christians, mollified by the concession, agreed to take part in the Assembly which soon afterwards was convoked; no steps, however, were taken to remedy the financial situation, which became the immediate cause of the disorders that followed. The refusal of the Porte to refund considerable sums which had been illegally diverted from the Cretan treasury or even to sanction a loan to meet immediate requirements caused no little exasperation in the island, which was increased by the recall of Karatheodory (March 1895). Before that event an Epitropé, or "Committee of Reform," had appeared in the mountains—the harbinger of the prolonged struggle which ended in the emancipation of Crete. The Epitropé was at first nothing more than a handful of discontented politicians who had failed to find places in the administration, but some slight reverses which it succeeded in inflicting on the Turkish troops brought thousands of armed Christians to its side, and in April 1896 it found itself strong enough to invest the important garrison town of Vamos. The Moslem peasantry now flocked to the fortified towns and civil war began. Serious disturbances broke out at Canea on 24th May, and were only quelled by the arrival of foreign warships. The foreign consuls intervened in the hope of bringing about a peaceful settlement, but the Sultan resolved on the employment of force, and an expedition despatched to Vamos effected the relief of that town with a loss of 200 men. The advance of a Turkish detachment through the western districts, where other garrisons were besieged, was marked by pillage and devastation, and 5000 Christian peasants took refuge on the desolate promontory of Spada, where they suffered extreme privations. These events, which produced much excitement in Greece, quickened the energies of the Powers. An international blockade of the island was proposed by Austria but rejected by England. The ambassadors at Constantinople urged peaceful counsels on the Porte, and the Sultan, alarmed at this juncture by an Armenian outbreak, began to display a conciliatory disposition. The Pact of Halepa was restored, the troops were withdrawn from the interior, financial aid was promised to the island, a Christian Governor-General was appointed, the Assembly was summoned, and an Imperial Commissioner was despatched to negotiate an arrangement. The Christian leaders prepared a moderate scheme of reforms, based on the Halepa Pact, which, with a few exceptions, were approved by the Powers and eventually sanctioned by the Sultan. On 4th September 1896 the Assembly formally accepted the new Constitution and declared its gratitude to the Powers for their intervention. The Moslem leaders acquiesced in the arrangement, which the Powers undertook to guarantee, and, notwithstanding some symptoms of discontent at Candia, there was every reason to hope that the island was now entering upon a period of tranquillity. It soon became evident, however, that the Porte was endeavouring to obstruct the execution of the new reforms. Several months passed without any step being taken in this direction; difficulties were raised with regard to the composition of the international commissions charged with the reorganization of the gendarmery and judicial system; intrigues were set on foot against the Christian Governor-General; and the presence of a special Imperial Commissioner, who had no place under the constitution, proved so injurious to the restoration of tranquillity that the Powers demanded his immediate recall. The indignation of the Christians increased, a state of insecurity prevailed, and the Moslem peasants refused to return to their homes. A new factor now became apparent in Cretan politics. Since the outbreak in May 1896 the Greek Government had loyally co-operated with the Powers in their efforts for the pacification of the island, but towards the close of the year a secret society known as the Ethniké Hetæria began to arrogate to itself the direction of Greek foreign policy. The aim of the society was a war with Turkey with a view to the acquisition of Macedonia, and it found a ready instrument for its designs in the growing discontent of the Cretan Christians. Emissaries of the society now appeared in Crete, large consignments of arms were landed, and at the beginning of 1897 the island was practically in a state of insurrection. On 21st January the Greek fleet was mobilized. Affairs were brought to a climax by a series of conflicts which took place at Canea on 4th February; the Turkish troops fired on the Christians, a conflagration broke out in the town, and many thousands of Christians took refuge on the foreign warships in the bay. The Greek Government now despatched an ironclad and a cruiser to Canea, which were followed a few days later by a torpedo flotilla commanded by Prince George. The prince soon retired to Melos, but on the night of 14th February a Greek expeditionary force under Colonel Vassos landed at Kolymbari, near Canea, and its commander issued a proclamation announcing the occupation of the island in the name of King George. On the same day Georgi Pasha, the Christian Governor-General, took refuge on board a Russian ironclad, and, on the next, naval detachments from the warships of the Powers occupied Canea. This step paralysed the movements of Colonel Vassos, who after a few slight engagements with the Turks remained practically inactive in the interior. The insurgents, however, continued to threaten the town, and their position was bombarded by the international fleet (21st February). The intervention of Greece caused immense excitement among the Christian population, and terrible massacres of Moslem peasants took place in the eastern and western districts. The forces of the Powers shortly afterwards occupied Candia and the other maritime towns, while the international fleet blockaded the Cretan coast. These measures were followed by the presentation of collective notes to the Greek and Turkish Governments (2nd March) announcing the decision of the Powers that (1) Crete could in no case in present circumstances be annexed to Greece; (2) in view of the delays caused by Turkey in the application of the reforms Crete should now be endowed with an effective autonomous administration, intended to secure to it a separate government, under the suzerainty of the Sultan. Greece was at the same time summoned to remove its army and fleet from the island, while the Turkish troops

*Insurrection of 1896-97.*

*Greek intervention.*

*Decision of the Powers.*

were to be concentrated in the fortresses and eventually withdrawn. The Cabinet of Athens, however, declined to recall the expeditionary force, which remained in the interior till 9th May, when, after the Greek reverses in Thessaly and Epirus, an order was given for its return. Meantime Cretan autonomy had been proclaimed (20th March). After the departure of the Greek troops the Cretan leaders, who had hitherto demanded annexation to Greece, readily acquiesced in the decision of the Powers, and the insurgent Assembly, under its president Dr Sphakianakis, a man of good sense and moderation, co-operated with the international commanders in the maintenance of order. The pacification of the island, however, was delayed by the presence of the Turkish troops and the inability of the Powers to agree in the choice of a new Governor-General. The prospect of a final settlement was improved by the withdrawal of Germany and Austria, which had favoured Turkish pretensions, from the European concert (April 1898); the remaining Powers divided the island into four departments which they severally undertook to adminster. An attack made by the Moslems of Candia on the British garrison of that town, with the connivance of the Turkish authorities, brought home to the Powers the necessity of removing the Ottoman troops, and the last Turkish soldiers quitted the island on 14th November 1898. On the 26th of that month the nomination of Prince George of Greece as high commissioner of the Powers in Crete for a period of three years (renewed in 1901) was formally announced, and on 21st December the prince landed at Suda and made his public entry into Canea amid enthusiastic demonstrations. After his arrival complete tranquillity has prevailed in the island. On 27th April 1899 the new autonomous constitution was voted by a constituent assembly, and in the following June the local administration was handed over to Cretan officials by the international authorities.

(J. D. B.)

**Cretinism.** See PATHOLOGY (metabolic diseases).

**Creuse,** a department in the central plateau of France, watered by the Creuse.

Area, 2164 square miles, distributed among 25 cantons and 266 communes. The population decreased from 284,942 in 1886 to 259,138 in 1901; births in 1899, 5176, of which 321 illegitimate; deaths, 4624; marriages, 2040. There were in 1896, 594 schools, with 43,000 pupils, and five per cent. of the population was illiterate. None of the towns has a large population. The returns for 1896 gave the total area under cultivation at 1,093,210 acres, of which 674,310 acres were plough-land and 316,160 acres grass land. In 1899 the wheat crop returned a value of £258,000, or less than half that of rye, £562,000. Potatoes yielded a crop valued at £490,000, and the natural pastures and grass lands £814,000. Hemp, which is largely cultivated, gave a return of the total value (in harl and in seed) of £400,000. Chestnut is also an important culture. The live stock of 1899 included 228,250 cattle, 645,690 sheep, 120,540 pigs, and 14,620 goats. 195,000 metric tons of coal were mined in 1898, but metallurgy is in a backward state.

**Creusot, Le,** or **Creuzot,** a town and railway centre of France, department of Saône-et-Loire, in the arrondissement of Autun, 34 miles in direct line north-west of Macon. The importance of its coal and iron mines, and vast engineering works of every description, has very much increased. The total number of persons employed in the coal mines exceeds 10,000, and about 9000 are engaged in the metallurgical departments. A network of railways with a total length of about 37 miles connects all branches of the works, which now occupy about 1000 acres. The output of the coal-field (Creusot and Blanzy) amounted in 1899 to 1,647,594 tons. Special attention is paid to the welfare of the workers, and excellent schools have been established. Population (1881), 15,740; (1896), 19,713, (comm.) 31,589; (1901), 30,175.

**Crevillente,** a town of Spain in the province of Alicante. Population in 1897, 9846. It is built on rising ground, its flat-roofed houses standing picturesquely amidst rock, nopals, cactus, dwarf palms, and orange trees. In its neighbourhood are two sources not far from each other, the waters of which differ 25° Fahr. in temperature, and are used for irrigation. The rugged territory around produces wine, olives, wheat, spart grass, and famed melons. The local industries are manufactures of warse stuffs, spart carpets, oils, and flour. There are a mediæval castle, two fine churches, and a town hall.

**Crewe,** a municipal borough (incorporated 1877, enlarged 1892) in the Crewe parliamentary division of Cheshire, England, 158 miles north-north-west of London, on the main line of the London and North-Western Railway. It is a railway junction where lines converge from Manchester, North Wales and Holyhead, Liverpool, North Stafford, and Hereford. It is inhabited principally by persons in the employment of the London and North-Western Railway Company. Crewe is not only one of the busiest railway stations in the world, but is the locomotive metropolis of the London and North-Western Railway Company, who have centred here enormous workshops for the manufacture of the material and plant used in their railways. In 1901 the 4000th locomotive was turned out of the works. Recently the station has been extended, both north and south, and a series of subterranean ways extending many miles have been constructed to enable merchandise traffic to pass through without interfering with passenger trains on the surface railways. The Railway Company have erected one of the finest electric stations in the world, and electrical apparatus for the working of train signals has been brought into operation. The station is fitted with an extensive suite of offices for the interchange of postal traffic, the chief mails to and from Ireland and Scotland being stopped here and arranged for various distributing centres. Its enormous railway facilities and its geographical situation as the junction of the great trunk lines running north and south, tapping also the Staffordshire potteries on the one side and the great mineral districts of Wales on the other, constitute it one of the most important links of railway and postal communication in the kingdom. The town owes its growth and importance to the London and North-Western Railway Company, who built its principal schools, provided it with a mechanics' institute, containing library, science and art classes, reading rooms, assembly rooms, &c., and also with baths. Victoria Park, also the gift of the Company, was opened in 1888. There are five Established churches, a Roman Catholic church, and many Nonconformist chapels. Two cattle-markets and a theatre have been erected. The corporation have just completed a technical institute and school of art. The area of the borough is 2193 acres. Population (1881), 24,385; (1891), 28,671; (1891) (on the area as afterwards extended), 32,783; (1901), 42,075.

# CRICKET.

THE era of the modern development of cricket may be definitely dated from the visit of the first Australian team to England in 1878. The previous twenty years had been devoted to the gradual improvement of the game throughout the country. But whilst the value of the work of the touring organizations had been enormous, interest in their encounters with local twenty-twos had steadily abated. The splendid prowess of the family of Grace set a new standard of ability, and the real value of county cricket began to be appreciated after the enactment that no cricketer could play for two counties in the same season. Many had previously played indiscriminately either for that of birth or residence, whilst one player, Southerton, represented four counties in the same season.

The development and modification of modern cricket have considerably altered the game. The improvement in the ground has caused the abolition of long-stop, once the most important place in the field, that position not having been filled in first-class cricket since 1877. Over-arm action in bowling is now universal, though occasionally lobs judiciously pitched and supported by unusually brilliant fielding have proved effective. The tendency of the modern attack is to bowl for catches rather than on the wicket; consequently the positions of the field have been much altered, three slips being quite common, and four having been at times required by very fast bowlers. Cover-point, whilst still an important post, is no longer so brilliant a situation as in the days when the Rev. V. K. Royle became famous; and leg hitting has so entirely departed—the last great exponent having been William Oscroft—that for some bowlers not a single man is placed on the on-side. At the same time the conviction must grow upon every careful observer that, whilst the increased precision of modern batting continually augments the disadvantages under which the bowler labours, this is not only due to the admirable condition of the turf, but also to a deterioration in fielding. Whether first-class cricketers participate in more matches than they are physically capable of playing at the top of their skill in all departments, or whether this additional handicap to the bowler is due to lack of unison between members of a side, the fact remains that the evil of giant scoring can be best remedied by improvement in fielding, which is largely a matter of personal effort, and without which the multiplication of matches is spoiling the perfection of the game.

The accessories of cricket are now very different from those in former days. Large pavilions with admirable accommodation for refreshment and dressing have replaced the old tents or "booths," whilst the general public now finds spacious covered stands and thousands of free seats on every county ground. The improved telegraph boards, giving the runs as scored and the numbers opposite the names of both batsmen and bowlers on the printed card, are even now inferior to those employed in Australia, where the entire score and bowling analysis is often displayed. The increasing amount of space devoted to the game in every daily paper, and the publication of the averages weekly during the season, indicate the enormous attention given by the press to the game, whilst signed articles by the most noted amateurs have become prominent in many popular journals, and the latest scores are a feature of each edition of the evening papers. The legislative power over the game is still vested in the Committee of Marylebone Cricket Club, consisting of sixteen members, four retiring annually. Their places are filled by general vote at the annual meeting of the club, when all the suggestions for legislation have to be ratified by a majority of those present. The new president of the club is annually nominated by the outgoing president at the dinner held on the same evening; but as this is badly patronized, it is now usual to mention the successor when responding to the customary vote of thanks at the meeting.

The line of demarcation between the professional and the *pseudo-amateur* has often given rise to much bitterness. It is of course the rule that any amateur, who desires it, may receive the money for which he is out of pocket in hotel and travelling expenses. But it has been asserted that a number of prominent amateurs derived large incomes under the guise of expenses. Until Dr W. G. Grace retired from Gloucestershire to take the direction of the London County Cricket Club at the Crystal Palace for five years at a salary of a thousand a year, the question of his expenses was continually cropping up. Lord Alverstone as chairman of the Surrey County Cricket Club, also stated, on the retirement of Mr. W. W. Read, that his case had been peculiar and would never become a precedent. Prowess at cricket has undoubtedly helped amateurs to get comfortable billets not only as schoolmasters, but in breweries, offices, and on the executive of county cricket clubs.

***Pay.***

A professional in first-class cricket obtains five pounds for each county match he plays, and his hotel bill and third-class railway fares in out-matches. It is the custom of many committees to give a sovereign to every professional who scores fifty runs, and money to those who perform the hat trick (*i.e.*, take three wickets with consecutive balls) or make a "century." Yorkshire, however, leaves the donation of "talent money" to the captain, whilst the M.C.C. give a bat to every amateur or professional who scores a century for them. Professionals have always received ten pounds when playing for Players *v.* Gentlemen at Lords, and a like sum was invariably paid in "test matches" (*i.e.*, between representative elevens of England and Australia) up to August 1896, when the five professionals selected demanded twenty pounds for their services. The affair created a great sensation, and eventually three of the five, having withdrawn their request, were included on the side. In all the test matches of 1899 twenty pounds was given to each professional employed. Every county professional of proved ability has the prospect of a benefit towards the end of his career, and the proceeds of the Whit Monday match at Lord's is annually devoted to the recompense of one of the professionals on the ground staff of the Marylebone Cricket Club. In December 1899, on Lord Hawke's instigation, it was resolved at a meeting of the county secretaries that "the counties should reserve direct control over the investment and disposal of all cricket moneys." The largest amounts have been recorded at Peel's benefit at Sheffield and Mold's at Manchester, when the subscription lists and the gate money in each case exceeded £2500. Many counties now give winter pay to their professionals at about fifty shillings a week, Yorkshire having been the first to set the example. Professionals in advanced years also derive benefit from the Cricketers' Fund, and obtain billets as coaches and groundmen. Umpires receive a pound a day, and each gets a cricket ball as a perquisite. The list of county umpires was first submitted by the counties to the Committee of M.C.C. in December 1882 to prevent any one standing when his own county was playing. Latterly the county captains have selected twenty umpires to act in the county matches of the following year.

The present rules differ in many respects from those in use in the middle of the last century. The trend of cricket legislation has been in three directions: (1) to put county qualification on a more equitable basis; (2) to enforce fair bowling; and (3) to increase the chances of bringing matches definitely to a conclusion.

*Laws.*

(1) The question of county qualification has been a matter of constant friction. The importations of Mr J. J. Ferris to Gloucestershire, and of Albert Trott and Roche to Middlesex, are examples of men qualifying from Australia. Mr F. R. Spofforth, of New South Wales, has played for Derbyshire, for which county the West Indian Mr C. A. Olivierre has qualified, whilst Mr G. C. B. Llewellyn and Mr C. O. H. Sewell, of the Cape, have played respectively for Hants and Gloucestershire. Some wealthy counties practically purchased skilled professionals born outside their boundaries, and county teams have been seen in which only two members on the side were actually qualified by birth. The rules had, however, stood unchanged since 1873, except for the addition in 1888 that a man can play for his old county during the two years that he is qualifying for another, until the new code came into operation in 1900. (2) Unfair bowling has been prevented so far as possible, but the umpires have often failed to agree in penalizing bowlers who were widely accused of throwing. The chief discussion arose over the delivery of Crossland, and after Lord Harris had openly made himself the spokesman of the malcontents an unfortunate difference arose between Notts and Lancashire. Just as the question of Crossland's action threatened to cause a serious schism, it was discovered that he had lost his residential qualification, so the matter terminated through a side issue, and Crossland was never no-balled by any umpire. There are six prominent instances of no-balling for throwing in first-class matches, the most sensational being those of Mr E. Jones in Australia, Mr C. B. Fry, Mold, and Tyler, the umpire in each case being James Phillips; in the two last-named cases even when the bowler was not at his end and he was standing at square-leg. Hopkins of Warwickshire was no-balled by Titchmarsh in 1898, and Captain Bradford of Hampshire by three umpires in 1899. The delivery of several great bowlers has been impeached, and Mr F. R. Spofforth in a letter to a sporting paper in January 1897 stigmatized both Mr T. R. M'Kibbin and Peel. The action of Mr M. A. Noble in the Australian team of 1899, of Mr W. C. Hedley, Mr W. F. Forbes, and Watson, all aroused marked difference of opinion. (3) The alteration of the follow-on rule and the legislation of the right of declaring an innings closed were made in consequence of two remarkable exhibitions in the university matches of 1893 and 1895, whilst in other cases batsmen had obviously knocked down their wickets. The result in minor matches has not been conducive to the popularity of the game, for instances have often been given of cricketers not getting an innings in several successive games; but in first-class fixtures Dr W. G. Grace is the only captain who has yet applied the closure and lost the game. The enormously increasing percentage of drawn games, now annually over 63 per cent., is attributed to the excellence of cricket pitches; and suggestions for heightening and broadening the wicket, reducing the size of the bat, deciding unfinished fixtures on the first innings, and giving the losers of the toss the option to bat first in the return match, have been widely discussed and thus far negatived. The Committee of M.C.C., in May 1900, tried the experiment of the abolition of boundaries by the erection of a netting round the ground. Several alterations were effected in the complicated system of scoring thus introduced, but the entire attempt was pronounced a complete failure and soon abandoned. The law of leg-before-wicket has also been much discussed, owing to the general objection to the growing habit of deliberately putting the body or legs in front of a breaking ball instead of playing it with the bat. To Gunn and Shrewsbury belongs the reputation of first regularly practising and perfecting a form of legitimate cricket absolutely at variance with the spirit of the game, and their example has been widely followed, to the detriment of the attractiveness of batting. In 1884 Lord Harris proposed that the side losing the toss in the first match should have the option of choice of innings in the return engagement; but this was never tried. In the previous year he had commented on the prevalence of illegal-sized bats, and in 1884 nearly all the prominent cricketers appeared with bats which had been shaven down to the proper width.

Lord Harris, 7th December 1886, proposed the establishment of a cricket council, which was organized 12th June 1887, a date practically coinciding with the centenary of the M.C.C. It was expressly stated that the new body should have no power over the laws of the game, but be competent to amend the rules of county cricket qualification, whilst at the meeting in December 1887 a discussion was raised on the leg-before-wicket question and on the reduction of scoring. In December 1889 Lord Cobham became chairman, on the appointment of Lord Harris to be governor of Bombay. On 11th August 1890, at the Oval, with Mr J. Shuter in the chair, the council received the report of the committee appointed to draw up a classification of counties. The scheme advocated that the shires should be divided into three sections, with the suggestion that the lowest county in the first and the highest in the second should, in the following season, play home-and-home matches, the winner to be qualified for inclusion in the premier body. On 25th October the representatives of the second-class counties held a meeting protesting against the proposed new legislation, Dr Russell Bencraft being in the chair. At the meeting of the cricket council on 8th December 1890, with Mr M. J. Ellison presiding, on the motion that the whole question of classification be discussed, Mr A. J. Webbe proposed as an amendment that the meeting be suspended *sine die*, which was carried by the chairman's casting vote, thus putting an abrupt and unexpected termination to the existence of this abortive assembly.

*Cricket council.*

The classification of counties was introduced by Mr Ellison at the meeting of the county secretaries December 1893, for the express purpose "of doing away with that very invidious distinction which had existed for some years and abolishing that hated word 'championship,' which the whole cricket world would be glad to get rid of." This opinion was proved to be erroneous. A special meeting was called for 1st May 1894, when an amendment was carried requesting the Committee of M.C.C. to consider and advise on the whole subject. The captains of the then first-class counties—Lord Hawke (Yorkshire), Dr W. G. Grace (Gloucestershire), Messrs J. Shuter (Surrey), S. M. J. Woods (Somersetshire), J. A. Dixon (Notts), F. Marchant (Kent), A. J. Webbe (Middlesex), W. L. Murdoch (Sussex), and A. N. Hornby (Lancashire)—sent in a resolution that the fixtures of Derbyshire, Essex, Leicestershire, and Warwickshire be regarded as first-class. This was ratified by the Committee of the M.C.C., who also included Hampshire in the following year. The consolidation of county cricket has since caused the line of demarcation to be very marked, but Worcestershire was elevated in 1899. The earliest mention of a county championship had been in 1870. For a long time con-

*County championship.*

servative folk and many prominent cricketers vigorously opposed what was to a great extent a creation of the sporting press. Popular opinion could not, however, be withstood, and it became presently evident that the interest of the public was most keenly aroused over the championship, although the notion of a trophy in commemoration of the annual achievement was universally scouted. Finally the recognition of the county championship was forced upon the Committee of the M.C.C., who laid down the rule that "one point shall be reckoned for each win; one deducted for each loss. Unfinished games shall not be reckoned. The county which, during the season, shall have, *in finished matches*, obtained the greatest proportionate number of points shall be reckoned the champion county." The old way, prior to this enactment, had been simply to regard the county which lost fewest matches as champions, taking no account of proportion. The actual result has been to concentrate not only popular attention but the best efforts of the foremost cricketers on county fixtures. Therefore, the interest in the first-class fixtures of the M.C.C. as well as other scratch teams has enormously diminished. Indeed, so important had county cricket become that it was thought necessary at the meeting of the secretaries in December 1895 to propose a motion pledging the first-class counties to give up any players required to represent England in the test matches.

The list of champion counties is :—

| | | Played. | Won. | Lost. | Drawn. |
|---|---|---|---|---|---|
| 1873 | Notts | 7 | 5 | 1 | 1 |
| | Gloucestershire | 6 | 4 | 0 | 2 |
| 1874 | Derbyshire | 4 | 3 | 0 | 1 |
| 1875 | Notts | 10 | 6 | 1 | 3 |
| 1876 | Gloucestershire | 8 | 5 | 0 | 3 |
| 1877 | Gloucestershire | 8 | 7 | 0 | 1 |
| 1878 | Middlesex | 6 | 3 | 0 | 3 |
| 1879 | Notts | 12 | 5 | 1 | 6 |
| | Lancashire | 10 | 5 | 1 | 4 |
| 1880 | Notts | 10 | 6 | 1 | 3 |
| 1881 | Notts | 13 | 10 | 0 | 3 |
| 1882 | Notts | 12 | 8 | 1 | 3 |
| | Lancashire | 14 | 10 | 1 | 3 |
| 1883 | Notts | 12 | 4 | 1 | 7 |
| 1884 | Notts | 10 | 9 | 0 | 1 |
| 1885 | Notts | 12 | 6 | 1 | 5 |
| 1886 | Notts | 14 | 7 | 0 | 7 |
| 1887 | Surrey | 16 | 12 | 2 | 2 |
| 1888 | Surrey | 14 | 12 | 1 | 1 |
| 1889 | Surrey | 14 | 10 | 3 | 1 |
| | Lancashire | 14 | 10 | 3 | 1 |
| | Notts | 14 | 9 | 2 | 3 |
| 1890 | Surrey | 14 | 9 | 3 | 2 |
| 1891 | Surrey | 16 | 12 | 2 | 2 |
| 1892 | Surrey | 16 | 13 | 2 | 1 |
| 1893 | Yorkshire | 16 | 12 | 3 | 1 |
| 1894 | Surrey | 16 | 13 | 2 | A tie |
| 1895 | Surrey | 26 | 17 | 4 | 5 |
| 1896 | Yorkshire | 26 | 16 | 3 | 7 |
| 1897 | Lancashire | 26 | 16 | 3 | 7 |
| 1898 | Yorkshire | 26 | 16 | 3 | 7 |
| 1899 | Surrey | 26 | 10 | 2 | 14 |
| 1900 | Yorkshire | 28 | 16 | 0 | 12 |
| 1901 | Yorkshire | 27 | 20 | 1 | 6 |

***County cricket.***

We now come to the performance of the counties. Notts has a great record. Daft and Oscroft with the bat, and Shaw and Morley, perhaps unrivalled as a pair of bowlers, left traditions well supported by Gunn and Shrewsbury, two exceptionally able batsmen. With them was associated Scotton, most patient of "stonewallers," whilst Barnes, Flowers, and Attewell did splendid service (the last-named being a remarkably steady bowler, keeping a good length, which gave him an abnormal number of "maidens"), and Sherwin was an excellent successor to Plumb and Wild at the wicket. Latterly Mr J. A. Dixon, for many years a vigilant captain, has seen a considerable decline in the fortunes of the county, the slow play of the home side alienating popular support at Trent Bridge until the advent of a dashing batsman in Mr A. O. Jones. With Shrewsbury, the latter scored 391 *v.* Gloucestershire in 1899, that being a "record" for first wicket. From 1873 to 1902 Notts won 155 matches, lost 90, and drew 109.

Gloucestershire, founded in 1871, and so long known as the county of the Graces, at the outset played an entirely amateur team. Apart from the prowess of the three famous brothers—E. M., W. G., and G. F. Grace—many fine cricketers have appeared on the side, such as in the earlier days Messrs F. Townsend, W. R. Gilbert, and J. A. Bush, a notable stumper; in the middle period, Midwinter, Mr J. Cranston, Mr O. G. Radcliffe, and Woof; more recently the colonial importations, Messrs J. J. Ferris and C. O. H. Sewell, and latterly that tremendous "slogger," Mr G. L. Jessop, and Mr C. L. Townsend, a remarkable left-handed batsman. From 1871 to 1902 Gloucestershire won 115 matches, lost 164, and drew 114. This county can boast the only cricketers who have scored 2000 runs and taken 100 wickets in the same season, namely, Dr W. G. Grace (1873), Mr C. L. Townsend (1899), and Mr G. L. Jessop (1900).

Lancashire, founded in 1864, has been directed by one of the hardest of hitters and best of captains, Mr A. N. Hornby. With his name will always be associated that of the patient Barlow. The bowling of Crossland, Nash, and Watson aroused discussion and evoked legislation on the nature of a fair delivery. The four brothers Steel did noble service when able to play, Mr A. G. Steel especially uniting marvellous skill with consummate theoretical knowledge. Briggs proved a clever left-handed bat, who gradually became one of the principal bowlers in England. Sugg, who migrated from Yorkshire and Derbyshire, was a very aggressive bat, and Pilling was the finest English wicket-keeper. A great professional bat of the defensive type is Albert Ward, and the present captain is the famous Harrovian, Mr A. C. MacLaren, who played in such magnificent form as to be chosen to occupy that post for England in the four last test matches with the Australians in 1899. He made the highest individual score in a first-class match, 424 against Somerset at Taunton in 1895. The success of Mold as a fast bowler, the excellent cricket of Cuttell, and the batting of Baker and Tyldesley, have alike proved invaluable. From 1873 to 1902 Lancashire won 228 matches, lost 106, and drew 105.

Yorkshire, whose county club was founded in 1861, was at one time a team of professionals, but of late years Lord Hawke has been the captain. Its team, always good, has played the best and most attractive cricket, culminating in the highest honours in 1900, when the side went through a programme of twenty-eight fixtures without sustaining a reverse. In the earlier period Ulyett, Hall, and Lockwood were the most notable bats, Bates and Emmett valuable all-round men, with Freeman and Hill as straight fast bowlers. As wicket-keeper, Pinder was succeeded in turn by the capable brothers Hunter. In recent cricket Brown and Tunnicliffe have become famous for their partnerships. In 1898 *v.* Derbyshire, at Chesterfield, their stand of 554 runs is a world record, whilst *v.* Surrey in 1897 they scored 328 for the first wicket. Tunnicliffe has also caught out more batsmen than any other fieldsman. Hirst and Wainwright have been efficient all-round men, of value to any side; Haigh is an excellent fast bowler, and Mr Ernest Smith a useful bat. Wilfrid Rhodes has also made a great name with the ball very early in his career, and in 1900, in county matches alone, he took 206 wickets for 12 runs apiece. The admirable all-round cricket of Mr F. S. Jackson has been of immense value, and Denton has done creditable work both with the bat and in the field. In earlier times Mr Sellars, Lee, and Preston were all successful, and Edmund Peate in his prime was never surpassed as a bowler. The county record to 1902 was 257 victories against 114 defeats and 131 draws.

Middlesex was founded in 1868 on the initiative of the renowned family of the Walkers, seven brothers, the record of whose prowess has been latterly written by Mr W. A. Bettesworth. The county team was subsequently controlled by Mr A. J. Webbe, a notable old Oxonian. Pre-eminent in a team relying much on amateur talent was Mr A. E. Stoddart, one of the grandest bats of any period and a shrewd judge of the game, whose retirement from county matches was universally lamented. Sir Timothy O'Brien in his prime was also very sound, and his performance with Mr G. F. Vernon against Yorkshire in 1895 will live in the annals of the game. The triumvirate of Studds—Messrs J. E. K., G. B., and C. T.—did fine work in the 'eighties, and a number of other university cricketers have assisted the metropolitan county: Messrs J. G. Walker, P. F. Warner, M. R. Jardine, E. A. Nepean, E. H. Buckland, F. J. N. Thesiger, B. J. T. Bosanquet, F. H. E. Cunliffe, F. G. J. Ford, W. J. Ford, A. F. J. Ford, J. Douglas, E. Lyttelton, R. N. Douglas, C. M. Wells, P. J. de Paravicini, P. J. T. Henery, C. I. Thornton, W. H. Hadow, and A. W. Ridley, may all be cited. Nor must the work of Messrs T. S. Pearson, S. W. Scott, E. M. Hadow, and J. Robertson be forgotten, and the lengthy services of Mr A. J. Webbe will be memorable in county annals. After the retirement of Mr Alfred Lyttelton, no stumper of ability could be found until the appearance of Mr Gregor MacGregor, the finest amateur wicket-keeper and a good captain. The attack—led by J. T. Hearne, most willing of good-length bowlers, and the spirited Australian, A. E. Trott, with such useful changes as Rawlin and Roche—is formidable. Trott both in 1899 and 1900 performed the hitherto unprecedented feat of scoring over

1000 runs and taking 200 wickets. From 1873 to 1902 Middlesex won 131 matches, losing 117, with 96 unfinished.

Surrey, one of the oldest counties, passed through vicissitudes when Jupp, Pooley, Southerton, and Humphrey grew old. Under the energetic direction of Mr J. Shuter they again came to the front, and for several years the excitement over the Bank Holiday match with Notts was intense, 63,763 people witnessing the game in 1892. So remarkable a cricketer as George Lohmann would alone have made a side famous, and he received admirable support from Beaumont and Bowley. In those days Mr W. W. Read was performing marvels with the bat, and Abel showed extraordinary ability, being the finest cricketer of his inches in the world. His biggest score was 357 not out *v.* Somerset in 1899. Maurice Read, a dashing hitter, Mr W. E. Roller, and the late Mr M. P. Bowden also did yeoman service. Mr K. J. Key then became captain; and Brockwell, a valuable and hard-working all-round player, sprang into prominence. With Abel he scored 379 *v.* Hants, 1897, the largest of many notable stands. Sharpe had a brief and sensational success with the ball, and Lockwood became almost as deadly as Lohmann. Yet more famous has been Tom Richardson, who from 1893 to 1898 was absolutely a terror to all Surrey's opponents, taking 1340 wickets for 20,000 runs. Hayward, nephew of the famous Cambridgeshire professional, gained fame as a wonderfully judicious bat; and his superb play in the test matches of 1899, when he averaged 65, may be considered the highest standard attained by any salaried cricketer. Mr D. L. A. Jephson, advancing on his university reputation, developed dogged defence combined with great punishing power, and became the only modern lob bowler of calibre. Surrey up to 1902 had won 212 victories against 138 defeats and 109 drawn games.

Sussex has always been hampered by lack of effective bowling and by the run-getting capability of the county ground at Brighton. In the 'eighties the performances were of the feeblest, but better days came when the Australian, Mr W. L. Murdoch, qualified. Of more value was the inclusion of Kumar Shri Ranjitsinhji, the Indian cricketer, whose dexterity and grace as a batsman have never been surpassed. He actually scored 2780 runs in 1896, averaging 57, while in county matches in 1899 he amassed 2555, averaging 75, and in 1900 his average of 83 was obtained for an aggregate of 2563 runs. Mr C. B. Fry is a brilliant bat; Mr P. H. Latham has scored largely; and Mr W. Newham, with Mr G. Brann, bore the brunt of the batting for fifteen years. The bowling, in spite of the brothers Hide, has always been weak, though the lobs of Walter Humphreys were sometimes puzzling, and Alfred Shaw emerged successfully from his retirement in 1894. Sussex from 1873 to 1902 could claim only 80 victories against 195 defeats, with 104 undecided fixtures.

Kent (the modern county club, dating from 1870) has varied considerably, and has played more cricketers in its team in the past twenty-five years than any other county. The incalculable value of Lord Harris as batsman and captain was terminated by his appointment as governor of Madras. In the earlier period Messrs Frank Penn and Ivo Bligh were the greatest batters, with Mr E. F. S. Tylecote as wicket-keeper. Then came Mr W. H. Patterson, a remarkably sound bat, and Rev. W. Rashleigh, with Mr M. C. Kemp behind the stumps, Mr Stanley Christopherson as bowler, and that hard hitter Mr F. Marchant. In 1898 the latter handed over the reins of office to the Wykehamist, Mr J. R. Mason, an admirable all-round cricketer, who has been assisted by the fast bowler Mr W. M. Bradley and by Mr C. J. Burnup, an obstinate bat difficult to dislodge. The family of the Hearnes have done admirable service for Kent, and the bowling of Martin and Wright has proved effective, whilst Blythe is useful with left-handed deliveries. From 1873 to 1902 Kent won 119 matches, lost 165, and drew 95.

Derbyshire, founded in 1870, fared so poorly after the decline of their two fast bowlers, Hay and Mycroft, that conspicuous failures in 1886 and 1887 caused the county to be dropped from first-class fixtures until 1895. The re-inclusion was due to the excellent all-round play of Davidson, the steady batting of Chatterton, and the fine cricket of Storer, a great wicket-keeper, who could bat and on occasion bowl. Hulme bowled well when health permitted. The achievements of the county, whilst reckoned first-class, up to 1902 were only 36 successes against 123 defeats, with 53 unfinished fixtures.

Somersetshire only came into the first rank in 1891, and has since played an attractive though not always a successful game. The retirement of the captain, Mr H. T. Hewett, a brilliant left-handed hitter, was an incalculable loss, though his successor, Mr S. M. J. Woods, has worked with untiring courage and ability. Mr L. C. H. Palairet, the best bat in the county, with Mr H. T. Hewett, scored 346 in partnership *v.* Yorkshire 1892. Messrs R. C. N. Palairet, V. T. Hill, and W. N. Roe, have been valued batsmen, Rev. A. P. Wickham and Mr A. E. Newton excellent stumpers, and Tyler a successful slow bowler. Up to 1902, 36 victories were scored against 89 defeats, with 39 unconcluded games.

Essex, a comparatively new county, owes its elevation in 1895 originally to the exertions of Mr C. E. Green. The eleven possesses a quartette of bowlers with notably diversified styles: Messrs C. J. Kortright, F. G. Bull, Mead, and Young. The batting of Messrs P. Perrin, C. M'Gahey, and A. J. Turner, with Carpenter, has been wonderfully good. No small part of the success is due to the presence of that fine player, Mr A. P. Lucas, who took part in the first test match in 1880, and twenty years later still averaged over 27. To 1902 the county had 41 gains to 36 losses and 50 undecided fixtures.

Warwickshire has played steady but unattractive cricket. Mr H. W. Bainbridge has proved valuable as captain and bat, the brothers Quaife have scored heavily though slowly, Diver has often made long innings, and Lilley has been pre-eminently the modern English wicket-keeper. The achievement from 1895 to 1902 was 28 victories against 35 defeats and 62 draws.

Leicestershire has been least successful of all. Apart from Pougher, Mr C. E. de Trafford has had no player of rank under his captaincy, though Woodcock is a straight fast bowler. From 1895 to 1902 only 16 wins, 67 losses, and 36 draws make a poor chronicle, and the batting collapses have been frequent.

Worcestershire, only promoted in 1899, owes its advance mainly to the capital cricket of the Foster family.

Largely relying on military assistance the form of Hampshire has been uncertain. The batting of Major Poore in 1899 has never been approached. In two months he scored 1399, with an average of 116. Grand batting capacity has also been displayed by Captain Wynyard. These two scored 411 *v.* Somerset in 1899 before they were separated. From 1895 to 1902, 24 wins, 62 losses, and 39 drawn games form the record of what is the oldest cricket county in England.

In December 1894 Mr P. H. Foley announced that the majority of the eighteen counties outside the important shires had agreed to the institution of a championship among the second-class counties. This met with complete success, though it was unfortunate at the outset that Cheshire, who had not lost a game in 1894, could not enter the competition. In 1895 Worcestershire was bracketed champion with Norfolk and Durham, though third according to the ruling of M.C.C. In 1896 Worcestershire came out easily first, with only one defeat inflicted by Northamptonshire, whilst in 1897 and 1898 they possessed an unbeaten record, which caused their elevation to the front rank. In 1899 Northamptonshire and Bucks obtained the highest percentage of points, though the record of Glamorganshire, who only lost one game to the Surrey Second Eleven, was infinitely superior. In 1900 Glamorganshire and Northamptonshire alike came through their list of fixtures without sustaining any defeat. It must be pointed out that the level of play in minor county cricket is of a standard distinctly lower than that of even the less successful first-class counties. In 1899 and 1900 the following minor counties played eight games apiece:—Northamptonshire (Mr T. Horton, captain), Bucks (Mr P. J. de Paravicini), Glamorganshire (Mr J. H. Brain), Norfolk (Mr L. C. V. Bathurst), Hertfordshire, Durham (Mr J. F. Whitwell), Northumberland (Mr F. G. Clayton), Wiltshire (Mr A. M. Miller), Berkshire (Mr A. C. M. Croome), and Cambridgeshire. Oxfordshire (Mr C. C. Bradford), Bedfordshire (Mr L. C. R. Thring), Devonshire, Cornwall, Monmouthshire, Rutlandshire, Cumberland, and Lincolnshire have also put elevens of varying ability in the field within the last few seasons. The popularity of cricket does not seem to progress much in either Scotland or Ireland, though the Dublin University crack, Mr Lucius Gwynne, twice played for Gentlemen *v.* Players, and proved himself a steady left-handed bat.

***Non-county cricket.***

The Marylebone Cricket Club has always remained the dominating authority on the game. Apart from its legislative powers, it has played an unparalleled number of matches. Between 1878 and 1899 no less than 3151 fixtures have taken place, of which the premier club won 1730, losing 607, with two ties and the remainder drawn. First-class fixtures between 1878 and 1902 numbered 289, of which 135 were successful, 105 ended in defeat, and 50 were unfinished. With increased interest in county fixtures, the engagements of M.C.C. with counties have latterly deteriorated into trial matches for promising colts, the best amateurs of the county often declining to encounter the weak and unsatisfactory elevens put into the field by the club even at headquarters. As an example of the increase in county fixtures, it may be mentioned that the match-list for the following season was first published in Lillywhite's *Annual* for 1882, and occupied two pages, whilst in the issue for 1899 the forthcoming matches filled nine pages. Mr Henry Perkins, as secretary to M.C.C., was in 1898 succeeded by Mr F. E. Lacey, who used to play for Hants, and represented Cambridge in 1882. The M.C.C. celebrated its centenary in 1887 by a banquet at which the president for the year, Mr E. Chandos Leigh, took the chair, the matches for the commemorative week being England *v.* M.C.C., and Ground and Gentlemen of M.C.C. *v.* Eighteen Veterans. In 1895 I Zingari celebrated their jubilee by playing the Gentlemen of England at Lord's. The historic wandering club is still paramount at the Canterbury Week, though county fixtures are now

the rule. Scarborough and Hastings also have important cricket festivals at the conclusion of each season.

The University match yearly sustains its importance and interest. Up to 1901, 66 matches had been played, of which Cambridge have won 32, Oxford 30, and 5 have been left drawn; 503 by Oxford in 1900, 388 by Cambridge in 1872 and 1892, and 365 by Oxford in 1892 are the highest totals. Mr R. E. Foster's 171 in 1900, Mr K. J. Key's 143 in 1886, and Mr M. R. Jardine's 140 in 1892, are the largest individual scores, whilst Mr K. J. Key and Mr C. E. M. Wilson have the best batting averages for the match. Eton has played Harrow 75 times, losing 32 and winning 28. The chief scores are Mr E. Bayley's 152 in 1841, and Mr T. G. O. Cole's 142 in 1897, the highest total being Harrow's 388 in 1900. Cricket is enthusiastically played at all the public schools.

Gentlemen *v.* Players at Lord's always forms the crowning tussle of the year. In addition to the companion but less representative fixture at the Oval, matches under this title have been played at Prince's, Scarborough, Brighton, and Hastings. Dr W. G. Grace has made fifteen three-figure innings—217 at Brighton, 215 at Oval, 174 at Scarborough, 169 at Lord's—all these being at the time records in the match on the ground. At Hastings he has scored 131, and at Prince's 110; but Gunn scored 169 at Hastings, and G. F. Grace 134 at Prince's. Abel made 247 at the Oval, whilst Mr R. E. Foster made 102 not out, and 136 in the same match at Lord's, Barnes 130, Brown 163. Altogether there have been 144 encounters, of which the amateurs have secured 51, and the professionals 70 matches, 22 being unfinished and 1 resulting in a tie. In 14 of these the aggregate exceeded 1000; in 1899, 1258 was scored at the Oval for 30 wickets, and in 1900, 1274 for 38 wickets, the Players going in to make 508 on fourth hands and winning by 2 wickets. North *v.* South has lapsed from its former position of importance, and M.C.C. *v.* England and Over Thirty *v.* Under Thirty have been dropped. Gentlemen no longer play I Zingari at Scarborough, nor does East oppose West. Smokers *v.* Non-Smokers proved interesting at Lord's in 1884, Notts played England in 1886, Surrey opposed England in 1895 (the testimonial match to Mr W. W. Read), Surrey and Sussex confronted England in 1898 and 1900, and the Home Counties played the Rest of England in 1899. Lord Sheffield's team, Daft's team, and both Mr A. E. Stoddart's teams played the Rest of England on their return from Australian tours, the last two defeating formidable opponents.

The visits of the Australian teams to England have aroused unparalleled interest and acted as an immense incentive to the game. The greatest sensation was caused when the first team on 27th May 1878 defeated a powerful M.C.C. eleven in a single day, disposing of them for 33 and 19, Mr Spofforth taking 6 wickets for 4 runs, and Mr Boyle 5 for 3, whilst the Australians fielded superbly. Their prowess was well maintained when, in September 1880, Australia for the first time met the whole strength of England, for though the Old Country won by 5 wickets the honours were fairly divided, especially as Mr Spofforth could not play. Dr W. G. Grace with a magnificent score of 152 headed the total of 420, but even finer was Mr W. L. Murdoch's imperturbable display, when he carried his bat for a superb 153. From 1882 onwards the Colonials, with two exceptions, at Blackpool and Skegness, only played eleven-a-side matches. Such bowlers as Messrs Spofforth, Boyle, Palmer, Garrett, and Giffen became household names. Nor was the batting less admirable, for Mr Murdoch was supported by Messrs Massie, M'Donnell, Bannerman, Horan, Bonnor, and Jones, whilst the wicket-keeper was the unrivalled Mr M'Carthy Blackham. This visiting side in 1882 was the greatest team of all; 23 matches were won, only 4 lost, and England was defeated at the Oval by 7 runs. In 1884 English cricket had improved, and the visiting record was hardly so good. The stupendous match against England at the Oval will never be forgotten. The Colonials scored 551 (Mr Murdoch 211, Mr M'Donnell 103, Mr Scott 102), and England responded with 346, Scotton and Mr W. W. Read adding 151 for the ninth wicket. Mr Scott's team in 1886 proved less successful, for all three test matches were lost, and eight defeats had to be set against nine victories, but Giffen covered himself with distinction. This was the first tour under the auspices of the Melbourne Club. M'Donnell's team in 1888 was rendered remarkable by the appearance of Messrs Turner and Ferris. The former took 314 wickets for 11 runs each, and the latter 220 for 14 apiece. To all appearance they redeemed a poor tour, 19 matches being won and 14 lost. The 1890 tour, though Mr Murdoch reappeared, proved disappointing, both the test matches being lost and defeats for the first time exceeding victories, though the two bowlers again performed marvellously well. After an interval of three years, Mr Blackham captained the seventh team, which was moderately fortunate. Messrs Graham and Gregory batted admirably, and the magnificent 149 of Mr J. J. Lyons, *v.* M.C.C., electrified spectators, and was perhaps the finest display of punishing cricket ever recorded. In 1896, though they did not win the rubber of test matches, the Colonials were most successful, 19 matches being victories and only 6 lost. Messrs Gregory, Darling, Iredale, Giffen, Hill, and G. H. S. Trott were the best bats, and the last-named made an admirable skipper. Mr H. Trumble kept an excellent length, and whilst the wickets lasted Mr E. Jones was deadly. Finally, the Australian representatives in 1899 demonstrated that they were the best since 1882, 16 successes and only 3 defeats (*v.* Essex, Surrey, and Kent) being emphasized by a victory over England at Lord's by the handsome margin of 10 wickets, the only one of the five test matches brought to a conclusion. The steady batting proved untiring, Messrs Noble and Trumper, both new-comers, being superb. The latter, *v.* Sussex, made 300, the largest individual score ever made by an Australian in England, the previous best having been 286 by Mr Murdoch in the corresponding match in 1882. Mr H. Trumble scored 1183 runs and took 142 wickets for 18 runs apiece, and Mr Darling not only made a judicious captain, but scored the biggest aggregate, 1941, ever obtained by any batsman touring with a Colonial eleven in England. On the home side, Hayward did sound service as a batter, and his stand with Mr F. S. Jackson in the fifth test match yielded 185 runs for the first wicket. In England the ten Australian teams have played 320 eleven-a-side matches, winning 149, losing 74, and leaving 97 unfinished. Their highest innings was 843 *v.* Past and Present of Oxford and Cambridge at Portsmouth 1893, and the highest against them 576 for England at Oval 1899. Their lowest was 18, *v.* M.C.C. in 1896, when Pougher took 5 wickets in 15 balls for no runs, and the lowest against them 19 by M.C.C. in 1878. Of the 24 test matches England has won 12 and the Australians 8.

***Australian matches.***

The first team to visit Australia was organized in 1862. George Parr took out the next in 1864, Dr E. M. Grace being the only amateur. In 1873 the Melbourne Club invited Dr W. G. Grace to take out an eleven, and three years later James Lillywhite conducted a band of professionals. On this tour for the first time Colonials contended on equal terms, one match *v.* Australia being won by 4 wickets and the other lost by 45 runs. Lord Harris in the autumn of 1878 took a team of amateurs assisted by Ulyett and Emmett, winning 2 and losing 3 eleven-a-side encounters, Emmett's 137 wickets averaging 8 runs each. Shaw, Shrewsbury, and Lillywhite jointly organized the expedition of 1881, when Australia won the second test match by 5 wickets. Mr Ivo Bligh in 1882 took a fine team, which was crippled owing to the injury sustained by Morley that eventually proved fatal. Four victories could be set against three defeats; Australia winning the only test match, owing to the batting of Mr Blackham. Shaw's second tour in 1884 showed Barnes heading both batting and bowling averages, while six victories counterbalanced two defeats. In the third tour Shrewsbury became captain, but the English for the first time encountered the bowling of Mr C. T. B. Turner, who took 27 wickets for 113 runs in two matches. Australia was twice defeated, the English captain batting in fine form. On this tour was played the Smokers *v.* Non-Smokers, when the latter scored 803 for 9 wickets (Shrewsbury 236, Mr W. Bruce 131, Gunn 150), against the bowling of Briggs, Boyle, Lohmann, Mr Palmer, and Flowers. The winter of 1887 saw two English teams in Australia, one under Lord Hawke and Mr G. F. Vernon, the other under Shrewsbury and Lillywhite. Both teams played well, the batting being headed by Mr W. W. Read with an average of 65, and Shrewsbury with 58. The ill-success of Lord Sheffield's team in two out of three test matches did not disprove the great merits of his eleven. Dr W. G. Grace headed the averages with 44, and received the best support from Abel and Mr A. E. Stoddart, whilst Attewell, Briggs, and Lohmann all possessed fine bowling figures. Mr A. E. Stoddart's first team (in 1894) achieved immense success and was the best of all. In the first test match they went in against 586 runs and ultimately won by 10 runs, Ward making 75 and 117. Mr Stoddart himself averaged 51, scoring 173 in the second test match, and Mr A. C. MacLaren, who made 228 *v.* Victoria, Brown, and Ward all averaged over 40. The last tour conducted by Mr A. E. Stoddart proved less satisfactory, four of the five test matches being lost, and some friction being caused by various incidents. K. S. Ranjitsinhji, who averaged 60 and made 175 in a test match and 189 *v.* South Australia, and Mr A. C. MacLaren, who scored five hundreds and averaged 54, were prominent, Hayward also doing good work; but the bowling broke down badly. Altogether, in Australia, the English teams have played 87 eleven-a-side matches, winning 52 and losing 27. Of the 26 test matches, 12 have been won and 13 lost.

***Other foreign visits.***

With regard to cricket in other parts of the world, many pleasant tours have been organized. The Philadelphians visited England in 1884, 1889, and 1897, when they won 2 and lost 9 games. Messrs G. S. Patterson, F. H. Bohlen, J. A. Lester, J. B. King, and R. S. Newhall have been the best amateurs. Teams of Canadian Gentlemen came in 1880 and 1887, whilst Haverford College enjoyed an instructive tour in 1897. Parsees arrived in 1884 and 1888, and one member of the side, M. E. Pavri, once played for Middlesex. Gentlemen of Holland made a modest pilgrimage in 1894. The

Cape team of 1894 won 12 matches and lost 7, Mr C. O. H. Sewell, who subsequently played for Gloucestershire, heading the batting, and Mr Rowe proving an excellent bowler, who captured 136 wickets for 12 runs apiece. A representative side from the West Indies were comparatively unsuccessful in 1900, though two coloured bowlers, Woods and Mignon, had fair averages, and Mr Olivierre, who headed the batting, remained to qualify for Derbyshire. Many visits have been paid to the United States. Irish amateurs toured in 1878 and 1892; and English teams were taken by Mr E. J. Sanders in 1885 and 1886, Lord Hawke in 1891 and 1895, Mr F. Mitchell in 1896, Mr P. F. Warner in 1897 and 1898, and K. S. Ranjitsinhji in 1899. Mr R. S. Lucas took a team to the West Indies in 1896, and both Lord Hawke and Mr A. Priestley had elevens touring in the islands in 1898. Mr A. E. Stoddart scored 1079, with an average of 53, making six hundreds, and capturing 104 wickets for 7 runs each. Mr P. F. Warner scored 984, with an average of 51, making four centuries. In April 1898 an English eleven visited Oporto under Mr Westray. India was visited by Mr G. F. Vernon's team in 1889 and by Lord Hawke's in 1892. All the above were strictly amateur combinations. Four tours have been made in South Africa—under Mr C. A. Smith in 1888, Mr W. W. Read in 1891 (when Mr Ferris took 235 wickets for 5 runs each), under Lord Hawke in 1896 (when Lohmann captured 157 wickets for 6 runs apiece), and in 1899 (when Haigh took 107 for 8 runs, and Trott 168 for 9 runs each). A very large proportion of the engagements of all these sides resulted in English victories, and the lavish hospitality left the pleasantest memories.

*Records* other than those already cited may be added for reference:—A schoolboy named A. E. J. Collins, at Clifton College, 1899, excited some interest by scoring 628 not out in a boys' match, being about seven hours at the wicket. Mr A. E. Stoddart made 485 for Hampstead *v.* Stoics in 1886. Melbourne University scored 1094 against Essendon in March 1898, this being the highest authenticated total on record. M.C.C. and Ground made 735 *v.* Wiltshire in 1888, the highest total at Lord's. In the match between Mr A. E. Stoddart's team and New South Wales at Sydney 1898, 1739 runs were scored, an aggregate unparalleled in first-class cricket. The lowest total in a first-class match is 12 by Oxford University *v.* M.C.C. and Ground at Oxford in 1877. The record for first wicket is 472 by Messrs S. Colman and P. Coles at Eastbourne in 1892. The longest partnership is 623 by Captain Oates and Fitzgerald at the Curragh in 1895. The best stand for the last wicket in a first-class match is 230 by Mr R. W. Nicholls and Roche for Middlesex *v.* Kent at Lord's in 1899.

The best *averages* for both batting and bowling in different seasons are appended:—

| Dr W. G. Grace . | 27,745 | 10,680 | 48,201 | 2653 | 18·447 |

No exhaustive summary on cricket could be complete without a tribute to the grand cricket of the Graces. Dr E. M. Grace has altogether taken 10,006 wickets, scored 72,482 runs and been the most daring field at point ever seen. Far greater has been the record of Dr W. G. Grace, who has made over a hundred centuries in first-class matches and has in four seasons scored three successive centuries. In 1871 his aggregate was 2739, and in 1895 he reached his thousand runs in May; he has always been a very crafty bowler, whose leg ball has dismissed scores of unwary colts. K. S. Ranjitsinhji, who in 1899 scored 3159 runs, and in 1900, 3065 runs, has even surpassed Dr W. G. Grace's performances with the bat. The feat of three consecutive hundreds has been scored, in addition to these two great batsmen, by Messrs C. B. Fry (who in 1901 made six in succession, besides scoring over 3000 runs altogether), E. G. Wynyard, A. C. MacLaren, W. L. Foster, R. E. Foster, Major Poore, Tyldesley, Abel, Hayward, Hirst, and Storer. But it must always be remembered that the batsmen of recent years have a great advantage in the improved grounds, as compared with Dr W. G. Grace's achievements twenty years before. To ensure some estimate of the comparative ability of the finest cricketers, an eminent judge selected, for the present article, the following as forming the three best modern elevens, it being calculated that each man is chosen on his form when in the prime of his career:—First World Eleven: Dr W. G. Grace, Dr E. M. Grace, K. S. Ranjitsinhji, Messrs A. E. Stoddart, A. G. Steel, J. M'C. Blackham, C. T. B. Turner, F. R. Spofforth, with Shrewsbury, Lohmann, and Peate. Second World Eleven: Messrs W. W. Read, G. Giffen, W. L. Murdoch, with Abel, Hayward, Gunn, Shaw, Peel, Pilling, Richardson, and A. E. Trott. Third World Eleven: Messrs P. S. M'Donnell, H. F. Boyle, F. S. Jackson, A. C. MacLaren, C. B. Fry, with Barnes, Briggs, Rhodes, Ulyett, Lockwood and Lilley or Mr G. E. M'Gregor. Messrs S. M. J. Woods, G. E. Palmer, C. T. Studd, and J. T. Hearne would be the reserves. (H. S. C. M. G.)

**Crieff,** a police burgh of Perthshire, Scotland, 18 miles west of Perth by rail. New Established and Free churches were erected in 1881, and a new United Presbyterian church in 1891. The academy was remodelled in 1878. The town grows in favour as a summer resort. Population of the police burgh (1881), 4469; (1891), 4902; (1901), 5706.

**Crimea.** See TAURIDA.

# CRIMINAL LAW.

THE article on Criminal Law in the ninth edition of the *Encyclopædia Britannica* deals with general principles, and it is not necessary to reproduce them save in the briefest fashion. A crime is an act which, by violating the law, affects injuriously not only the civil rights belonging to an individual but also the public rights and duties due to the whole community. The sovereign is taken to be the person injured by the crime, as he represents the whole community, and he is nominally the prosecutor of crime. Criminal law includes the rules as to the prevention of crime, the investigation of crime, the prosecution of crime, the punishment of crime. It lays down what constitutes a criminal offence, what proof is necessary to establish the fact of a criminal offence and the culpability of the offender, what excuse or justification for the act can be legally admitted, what procedure should be followed in a criminal court, what degrees and kinds of punishment should be imposed on the various offences which come up for trial. Finally, it regulates the constitution of the tribunals established for the trial of offences according to the gravity of the infraction of law, and deals with the organization of the police and the proper management of prisons, and maintenance of prison discipline. (See EVIDENCE, PRISON DISCIPLINE, and POLICE.)

***Definition of crime.***

Criminal and civil law, however, overlap, and in all offences where an individual has suffered loss, he can claim damages in a civil court from the wrong-doer. Again, there are many minor offences established by statute which cannot be said to have a strictly criminal character, although the case is tried by a magistrate with criminal powers, and the result of the case is in a sense penal because it consists solely in a fine or penalty, or sometimes a short term of imprisonment is also imposed. Any statutory nuisance, such as improper emission of smoke from a chimney, or the failure to repair a highway, or the carrying on of certain trades in close proximity to inhabited houses, are all tried as criminal offences, although they cannot be described as crimes. Crimes—the word is here intended to include all breaches of the criminal law—may be divided into (*a*) crimes which affect public order, abuses and obstructions of public authority, offences which are injurious to the public at large; (*b*) offences against the person, offences against parental and conjugal rights; (*c*) offences against property, by way either of force or fraud.

There are three classes of crimes—treason, felony, and misdemeanour—in addition to a large number of petty infractions of law known as summary offences. The distinction between felony and misdemeanour, though still maintained in the English system, has no longer any logical basis. Formerly all felonies, including treason, involved forfeiture of goods and property, whilst misdemeanours were not treated as felonies and did not involve forfeiture. Forfeiture is no longer a legal punishment, and whenever English criminal law is codified the distinction will no doubt disappear and a new classification be introduced.

***Treason, felony, and misdemeanour.***

*Treason* in England is a crime of a special character. The offence of treason is the attempt by overt acts either to upset the Government of the country or to kill or personally injure the sovereign or his family. The offence at common law was never concisely defined, and depended too much on the discretion of the king and his judges. It was limited by legislation so long ago as 1352 by what is called the Statute of Treason. The punishment for treason was beheading, with other brutal accompaniments. The barbarous features of the punishment were abolished in 1799. The severity of the punishment, *i.e.*, death, led in 1848 to the constitution of Treason Felonies, which are, like treason proper, of a special character, but are now tried as ordinary felonies. Whilst the compassing of the death of the sovereign or his deposition, or levying war upon him, remain punishable with death, lesser treasonable acts are punishable with penal servitude. The procedure for treason was formerly of a very oppressive character, and was made more reasonable in 1695. The offence is now tried on indictment and by a jury at the Court of Assize in the same manner as ordinary felonies. Persons indicted for treason (1) can have a copy of indictment five days before trial; (2) can have counsel; (3) can produce witnesses, who will be heard on oath. On charges of treason, bail may not be granted except by order of the Secretary of State or of the High Court.

The distinctions between felonies, misdemeanours, and summary offences are of considerable importance. Thus a person guilty of felony can be arrested by any person without a warrant; a person guilty of misdemeanour cannot, unless by a constable in special circumstances, be arrested without a warrant. Further, a person charged with a misdemeanour or summary offence is entitled to be released on bail, *i.e.*, on the obtaining of sureties, who are bound under the penalty of paying a sum of money to produce the prisoner charged for his trial on the day and at a place named. The sureties must be sufficient in the opinion of the court, and as a rule only householders are accepted. Bail is obligatory in all misdemeanours, with the exception of misdemeanours where the costs of the prosecution are payable out of the county or borough rate or fund. It is obligatory in all summary cases. But a person charged with felony is not entitled as of right to be released on bail, but may be so released at the discretion

of the judge or justice dealing with the case. In the procedure for the trial of felonies and misdemeanours there are several differences as regards: (*a*) the right of challenge, that is to say, the right of either party to challenge jurors, which is equivalent to an exception for one or more of the jurors, who have appeared individually, and who in consequence of the challenge are set aside. In the case of felonies the defendant may challenge peremptorily twenty jurymen; in the case of misdemeanour he has no right to peremptory challenge, but has to show justification for his challenge.

(*b*) The withdrawal of the jury from communicating with the outside world during the pendency of the case.

(*c*) The obligatory presence of the person charged. In the case of misdemeanour the court may permit his absence. Formerly, on conviction of the offence of felony, forfeiture of lands and goods ensued. But forfeiture resulting on a conviction of felony was abolished in 1870, and the distinction of felony and misdemeanour with regard to forfeiture, as already stated, now only exists in the unusual case of outlawry.

Whether a crime is a felony, misdemeanour, or a summary offence depends chiefly on the heinousness of the offence. But a few misdemeanours, created by statutes of Victoria's reign for punishing frauds of modern origin, are punishable more severely than some felonies. However, as a rule all the more serious offences are felonies, and the most trivial offences are summary offences, whilst misdemeanours come between the two categories. Many summary offences are what some writers call *mala prohibita*, as distinguished from *mala in se*; that is to say, they do not involve any breach of ordinary morality, except such breach as is involved in any violation of positive law.

The chief common law *felonies* are: homicide, rape, larceny, *i.e.*, in ordinary language, theft, robbery, *i.e.*, theft with violence, burglary, and kindred offences; counterfeiting the coin has been made a felony instead of being treason; and forgery of most documents has been made felony instead of being, as it was at common law, a misdemeanour.

Among the chief *misdemeanours* the following may be mentioned:—

1. Assaults on the Sovereign.
2. Unlawful assemblies.
3. Riots and seditious offences.
4. Forcible entries.
5. Perjury.
6. Blasphemy.
7. Extortion.
8. Bribery.
9. Minor bodily injuries.
10. Assaults.
11. Common nuisances.
12. Libel.
13. Conspiracy to defraud, &c.

Perjury was, until the year 1563, punished solely by the ecclesiastical courts, but since that year it has been punished, like any other misdemeanour, by a civil court.

Examples of *summary offences* are as follows:—

1. Offences by children (under twelve years).
2. Offences by young persons (twelve to sixteen years).
3. Offences by adults (above sixteen years), in cases of larceny and embezzlement.
4. Common assaults.
5. Certain larcenies not indictate.
6. Small wilful injuries to property.
7. Offences relating to game.

**Trial of a peer.**

The criminal law applies in England to all persons alike, with the sole exception of a peer or peeress charged with felony, who has the right to be tried by the House of Lords. An Earl Marshal is appointed. He presides over the House of Lords to try the indictment. When the trial is over, the staff, which is the sign of his office, is broken, and the Earl Marshal ceases to exist as the president of this special court.

**Special tribunals.**

There are in England no courts of a special character, such as exist in some foreign countries, for the determination of disputes between the governing classes themselves or with the governed classes, whether of a civil or criminal character. Special tribunals do indeed exist for trying naval or military offences committed by members of the navy and army, but those members are not exempt from being tried by the ordinary tribunals for civil offences, as though they were civilians.

**Benefit of clergy.**

The *punishment* for crimes by English law was formerly most brutal, but this brutality was tempered partly by the law of Benefit of Clergy, partly by the rigid adherence to singular technicalities, as, for instance, acquitting a criminal because the person whom he was charged with killing had two Christian names, whereas one only was mentioned in the indictment, or because the name of the person killed was wrongly spelt in the indictment. Benefit of clergy began with the claim of the ecclesiastical authorities that they alone should punish a clerk. The term clerk always included a large number of persons in what were called minor orders, and after a time the test of being a clerk was ability to read, and thus everybody who could read obtained exemption from punishment for his crime, as the ecclesiastical authorities practically enacted no punishment. This practice led to Parliament declaring certain offences to be felonies without benefit of clergy, in order to ensure punishment in all cases of offence against life or property.

Bentham pointed out at the beginning of the 19th century that certainty of punishment was more effective than severity, that severe punishments induced juries to acquit criminals, and thus the certainty of punishment was diminished. But his arguments and the eloquence of Sir Samuel Romilly produced no effect until after the reform of Parliament in 1832, shortly after which Acts were passed abolishing the death sentence for all felonies where benefit of clergy existed. Benefit of clergy was finally abolished in 1827 (7 & 8 Geo. IV. c. 28). At present no offences are capital except treason, murder, piracy accompanied by violence, setting fire to the royal dockyards, and inciting to mutiny. The severity of the capital sentences had already been modified by the pardoning power of the Crown, which directed the convict to be transported to convict settlements in the Colonies instead of being hanged. For some years this was only done by the consent of the convict, who agreed to be transported if his death sentence was remitted, but in 1824, when a convict refused to give this consent, Parliament authorized the Crown to substitute transportation for a death sentence.

**Punishment.**

About the middle of the 19th century the Colonies objected to receive any more convicts. Transportation was prohibited in 1857, and penal servitude within the United Kingdom was substituted for transportation; whilst for many felonies imprisonment with hard labour for a term not exceeding two years may now be substituted for penal servitude. By the Penal Servitude Act, 1864, the shortest period of penal servitude for an offence committed after the passing of the Act is five years, and where any previous Act had fixed a maximum of less than five years, the period of five years is to be substituted for such shorter term. The distinction between penal servitude and imprisonment with hard labour is rather one of prison management and discipline than one of any principle. The punishment for misdemeanour at common law has always been fine or imprisonment, or both, at the discretion of the court before which the prisoner was convicted. To this simple imprisonment hard labour has been added by statute for various offences, but the term for imprisonment with hard

labour is limited to two years. The punishment for summary offences is imprisonment with or without hard labour, or a fine, or both, subject to limitations which as a rule do not allow imprisonment exceeding six months. When the punishment may exceed three months' imprisonment, the accused has a right to demand that the offence shall be tried by a jury as a misdemeanour and not summarily.

In the case of treason and murder the court has no discretion as to the punishment awarded, and in most other cases some limitation is imposed by statute on the length of penal servitude or imprisonment with hard labour which may be imposed. But the maximum in every case is so high that, save in treason and murder, the court has a very large discretion as to the punishment to be imposed, and is not as a general rule limited, outside the offences of treason and murder, in its discretion as regards the minimum of punishment which it can award. Together with the mitigation of punishment since 1832, laws have been passed for getting rid of the technicalities which formerly led to the improper acquittal of criminals. Indeed the looseness of pleading in criminal cases is carried almost too far; for while there is no danger in such looseness when times are quiet and when law is administered by the judges of the High Court in England. Yet when crimes of a certain character are committed in times of great political excitement and the law is administered by an inferior judiciary, there may be some danger of injustice if the strictness of pleading and procedure is too much relaxed.

The punishments which may be imposed summarily are as follows:—

(a) In the case of adults pleading guilty to offences involving property worth over 40s., imprisonment not exceeding 6 months, without the option of a fine.

(b) In the case of adults where the offence affects property not worth over 40s., imprisonment not over 3 months, or fine not exceeding £20.

(c) In the case of young persons, imprisonment not over 3 months, or fine not exceeding £10.

(d) In the case of children, imprisonment not over 1 month, or fine not exceeding 40s.

If the offence is trifling, the accused may be discharged without punishment, and under the First Offenders Act (1887) the justices have a discretionary power to forego punishment. The justices have also the power, under the Reformatory Schools Act and the Industrial Schools Act, to commit youthful offenders to one or other of these institutions,—in the case of a previous conviction, the Industrial School; in the case of a first offence, the Reformatory (see INDUSTRIAL SCHOOLS).

Crime is in England treated locally; the responsibility for the suppression of it is local. Formerly each township was responsible for the suppression of crime within its own boundaries. The "view of frank pledge" which gave effect to this has long since disappeared, but the system of each township having a headborough or constable still survives in a few places. In each county the sheriff was, and in law still is, responsible for the peace of the county, and he had control of the county jail, in which he lodged the prisoners he arrested as suspected of crime. In ancient times the freeholders of the county sat, with the sheriff presiding, to inquire into and punish the crime in the county. The Sheriff's Criminal Court, being superseded by the Assizes and Quarter Sessions, was long ago abolished, but the tribunal at the Assizes for the trial of crimes is still furnished by the freeholders of the county, acting as jurymen under the direction of the judge. The jury must come from the vicinage or neighbourhood. The judges, who used to be

*"View of frank pledge."*

sent on a commission of jail delivery and "*oyer* and *terminer*" from Westminster, are now from the Royal Courts of Justice, and not from Westminster. In olden days, and even now in theory, the Grand Jury inquire of their own knowledge, by the oath of good and lawful men of the neighbourhood, into the crime of the county, but in practice the charges against the accused persons are always submitted to an officer known as the Clerk of the Crown. The Grand Jury is first instructed as to their inquisition by a charge from the judge, as regards the indictment concerning which they are called upon to examine, whether there is a *primâ facie* case to send for trial to the ordinary jury. The Grand Jury must consist of not less than twelve, not more than twenty-three, good and lawful men of the county. But any person who prefers an indictment is entitled to put it forward, provided he submits to be bound over to prosecute and to be liable to costs in case his prosecution fails. Such cases are very rare. As a rule, in the big towns a solicitor is specially appointed to direct criminal prosecutions; in the rural districts it may be the person injured, it may be the magistrates' clerk, it may be a policeman who is bound over to prosecute.

*The Grand Jury.*

The Clerk of the Crown puts the charges into proper shape, and lays them before the Grand Jury. The charges are then called Bills, and if the Grand Jury considers that there is no *primâ facie* case, the foreman endorses the Bill with the words "no true case," and then presents it to the judge. The jury are then said to have ignored the Bill, and if the person charged is in custody he is released, yet liable to be tried on better evidence.

When an indictment is found by the Grand Jury (twelve at least must concur), the person charged is brought before the court, the indictment is read to him, he is asked whether he is guilty or not guilty; if he pleads guilty, he is then sentenced by the court; if he pleads not guilty, a petty jury of twelve is formed out of the number of jurors who have been summoned by the sheriff to attend the court. He is tried by these jurors in open court; he can, if he choose, have counsel to defend him, by cross-examining the witnesses, by calling witnesses of his own, and by addressing the jury. The judge then sums up the case to the jury, and they acquit or convict him. If he is acquitted, he is discharged from custody; if convicted, the judge awards the sentence. From such acquittal or conviction, properly speaking there is no appeal in criminal trials. The verdict of the jury is final. Any considerable defect or informality in the procedure may be taken before the King's Bench by Writ of Error, but such cases are not now of frequent occurrence. And if any question of law arises at the trial, the judge may reserve it for the opinion of the court for the consideration of Crown Cases Reserved, by whom the conviction may be either quashed or confirmed.

*Procedure before petty jury.*

The question of criminal appeal has been, and still is, a matter of great controversy. On the Continent of Europe, and even in India, appeal is allowed in criminal cases on the facts as well as on the law of the case. In England an appeal on questions of law arising at the trial is allowed, as stated above, but the procedure is intricate and technical, whilst no provision whatever is made for questioning the decision of the jury on matters of fact. The verdict of a jury, however unsatisfactory, cannot be reversed, and the only remedy is founded on the prerogative of pardon inherent in the Crown, which is exercised, as a matter of fact, by the Home Secretary. Various proposals have been made, the most practical being that a new trial shall be granted (1) when the verdict is obviously against the evidence, (2) when new

*Criminal appeal.*

facts have arisen after the trial, proving the verdict conclusively wrong. The exercise of the power of pardon in the prerogative of the Crown does not satisfy the justice of the case—it only accords mercy where there may be no criminal guilt. Moreover, as it is given on the advice of the Secretary of State, and his inquiry must necessarily be informal and without publicity, cases might arise where a pardon would not satisfy public opinion. At the same time, celerity of punishment is absolutely necessary for the repression of crime, and so far no system of criminal appeal has duly satisfied that requirement. The Court of Crown Cases Reserved consists of a number of judges of the High Court—not less than five—and from their decision there is no appeal.

The indictment must say that it is found by a jury of a particular county, and the offence charged must appear to have been committed in that county; this is known as the *venue*, and in former days, at any rate, was a great protection against the oppression of the subject on the part of the Crown. It prevented the Crown in the days of its great power from removing a person whom it wished to get rid of from among his neighbours, and placing him on trial in a strange place where the influence of the Crown was greater. This is still true to a certain extent, as great injustice may be caused to a man by removing him from his neighbours and trying him at a distance from his friends and from the witnesses whom he might call for his defence. In Ireland, for instance, the greatest injustice might be done by removing an Orangeman from Belfast and trying him in a Roman Catholic county. But it has its evils where the area from which the jurors are drawn is a small one, such as a town of a few thousand inhabitants. In that case a man charged, say, with fraud, may be protected by his friends from being properly punished for that fraud. In 1856 power was given for the first time to remove a prisoner for trial from any part of England to the Central Criminal Court. This was originally done in favour of a prisoner against whom there was great local animosity, but so long as the law is administered in quiet times by judges of the High Court there is no danger of injustice to any accused person.

***The venue.***

It has been mentioned above that in theory an indictment is the spontaneous act of the Grand Jury, but that in practice a Bill for that indictment is always presented by some individual to the Grand Jury. In theory the prosecution is on the part of the Crown; and this is so far true in fact that the Attorney-General, on behalf of the Crown, can in any case intervene, and either take the conduct of the prosecution out of the hands of the private person or enter what is called a *nolle prosequi*, which has the effect of stopping any further prosecution; but in practice such a course is never taken.

It is obviously necessary that criminals should be arrested as soon as possible after the crime is committed, and that the arrest should not wait until an indictment has been found. Hence a practice has grown up, which has been largely extended of recent years, of having a preliminary inquiry of the crime before justices, the effect being that if there is no *primâ facie* case a man is at once discharged, instead of being kept in custody until the Assizes are held, and the Grand Jury can inquire into the case. This procedure before justices was regulated by an Act of 1848, known as Jarvis's Act, and is now almost universal. This procedure before justices is entirely different from the procedure for summary offences. It may be, though usually it is not, held in private; it is an inquiry and not a trial; the justices have to consider not whether the man is guilty, but whether there is such a *primâ facie* case against him that he ought to be tried. If they think that there is, they commit him to prison to wait his trial, or require him to give security, with sureties, to the amount named by them for appearing to take his trial.

***Preliminary inquiry.***

If a coroner's jury, on inquiring into any sudden death, finds that murder or manslaughter has been committed, that finding has the same effect as an indictment by a grand jury, and the man charged may be tried by the petty jury accordingly. The law and procedure of the Coroner's Courts are now regulated by the Coroners Act, 1887 (50 & 51 Vict. c. 71). When there is a dead body of a person lying within the area of his jurisdiction, and there is reasonable cause to suspect that such person died a violent or unnatural death, or a sudden death of which the cause is unknown, or has died in prison, the coroner's decision to hold an inquisition cannot be challenged. The verdict of guilty is followed by trial in the ordinary manner.

***Coroner's courts.***

For many years the costs of the prosecution of felonies, and also of many misdemeanours, were paid out of the public funds, raised in each county. After 1852 an annual sum was voted by Parliament for the reimbursement of half, and then of all, these costs to the counties, or rather localities, which paid them, and thus the cost of these prosecutions fell upon the Imperial Exchequer. In 1888 the proceeds of certain taxes were handed over to the local authorities, and they again became liable to pay these costs.

With the organization of the police forces, which began about the year 1827 in London, and in 1834 in the United Kingdom generally, the police became the prosecutors in many cases. In 1879 an Act was passed (42 & 43 Vict. c. 22, amended by 47 & 48 Vict. c. 58) providing for the payment of a director of public prosecutions, who was to act under the Attorney-General in such cases and under such conditions as might be settled by rules laid before Parliament, and in 1884 a further Act developed the system of the Act of 1884. The office of director is now held by the officer who, for the time being, is solicitor to the Treasury. He is subject to the direction of the Attorney-General; and in the cases provided for by the rules, which may be roughly taken to be the cases of the most serious crimes, or of crimes which require long and careful investigation, undertakes, always with the approbation of the Attorney-General, the prosecution in place of the private individual.

***Director of public prosecutions.***

The Attorney-General has always represented the Crown in criminal matters, and in State prosecutions appears in person on behalf of the Crown, and when he so appears has certain privileges as respects the reply to the prisoner's defence and the mode of trial. The Attorney-General has a right on behalf of the Crown to institute in the High Court, by information, a prosecution for any misdemeanour, but he cannot so institute a prosecution for felony; any such information is tried by a jury in like manner as if it were an indictment. Preliminary jurisdiction in criminal cases is possessed by the Justices of the Peace, who may also under special Acts convict in a summary manner for offences of minor importance. The procedure for punishing summary offences is before two justices, or in the case of a stipendiary magistrate, one justice. This proceeding must not be confused with the preliminary procedure already mentioned before justices for an indictable offence, nor with the procedure before justices in relation to civil matters, such as the recovery of small sums of money. The proceeding begins either by the issue of a warrant for the arrest of the person charged, in which case a sworn information must be filed, or by a summons directing the person charged to appear on a certain day to answer the complaint made by the prosecutor. The jus-

tices hear the case in open court; the person charged can make his defence either in person or by his solicitor or counsel, he can cross-examine the witnesses, for the prosecution, call his own witnesses, and address the justices in his defence. The justices, after hearing the case, either acquit or convict him, and in case of conviction award the sentence. If the sentence is a fine and the fine is not paid, the person convicted is liable to be imprisoned for the term fixed by the justices, not exceeding a scale fixed by an Act of 1879, the maximum of which is one month. The imprisonment may be with or without hard labour.

*Procedure for summary offences.*

Of late years this summary jurisdiction of the justices has received very large extensions, and many offences which were formerly prosecuted as serious offences by an indictment before the Court of Assize or Quarter Sessions have, where the offence was a trivial one, been made punishable, on summary proceedings before justices, by a small fine or a short term of imprisonment.

The extension of the jurisdiction of the justices is open to the observation that it deprives a person charged of the protection of a jury, and also that it throws upon him, if convicted, and upon the prosecution if there is no conviction, the cost of the proceedings. The former objection is much mitigated by the enactment made in 1879, that a person if liable on conviction to be sentenced to imprisonment for more than three months, or to a fine exceeding £100, can claim to be tried by a jury. But the objection as to the costs remains, and the payment of costs is often a very serious addition to the trivial fine; and it is anomalous that a person convicted of a trifling offence should bear the cost of the prosecution, while if he is convicted before a superior tribunal of the most serious offence he does not pay the cost.

The Criminal Evidence Act, 1898, is explained in the article on EVIDENCE; but as it goes to the root of the English system of criminal trials, this article requires a brief reference to it. Bentham wrote that amongst the singularities of the English common law the most remarkable is the rule that does not allow any questions to be put to the accused which might lead to the proof of his guilt. Sir James Stephen rather defended the rule, because it stimulated independent inquiry. Other writers maintained that any interrogation of the prisoner would be contrary to the principle "nemo tenetur se ipsum accusare." On the Continent of Europe the prisoner can be interrogated; and the Criminal Evidence Act, 1898, now enables every person, and the wife or husband of such person, to be a competent but not compellable witness for the defence at every stage of the procedure. No comment is allowed by the prosecution on the abstention of the accused or the accused's wife or husband from giving evidence. Cross-examination is allowed, but previous convictions and bad antecedents are not allowed to influence the court, which is bound to judge according to the facts presented to it. The Indian procedure does not go so far as this English reform. The court is empowered to ask the accused questions generally on the case after the witnesses for the prosecution have been examined and before he is called for his defence. His answers are taken into consideration, and the court and the jury may draw such inference from the answers as appears just. The accused does not render himself liable to punishment by refusing to answer or by giving false answers. Theoretical objections often do not stand the test of practice, and the Criminal Evidence Act, 1898, has given satisfaction. In England, as already pointed out, although the prosecution is in the name of the Crown, and although a public prosecutor has been appointed, still criminal charges are conducted, with few exceptions, by the person injured, with the assistance of the police. In the Prosecution of Offences Acts of 1879 and 1884 there is to be found the nucleus of the system of the public action such as obtains in other countries in case of crime. Under these Acts the Solicitor to the Treasury acts as Director of Public Prosecutions under the Attorney-General. But both these high officials have many other duties, and the outcome of the present system, worked as it is now, is small. The annual average of cases by jury on indictment for the five years ending 1897 was 11,633; if the indictable cases disposed of summarily were included, the annual average would be 55,174. Yet in 1897 only 414 cases were prosecuted by the Public Prosecutor. In Ireland the system is nominally the same as in England, but in practice almost all prosecutions are instituted and conducted under the direction of the Attorney-General for Ireland, who is a member of the Government of the day, and so responsible to Parliament, as in the case of the Lord Advocate. In Ireland, owing to the police being a centralized force, under the management of Commissioners residing in Dublin, any prosecution which in England might be conducted by the local police, would in Ireland be conducted under the direction of the chief of the police in Dublin, who is neccessarily in close communication with the Attorney-General.

*Evidence.*

In *Ireland* the law relating to crimes is nearly the same as in England, but in *Scotland* hardly any crimes are constituted by statute law, the common law being to the effect that if a judge will direct any act to be a crime, and a jury will convict, that act is a crime. This great elasticity of the common law to include every sort of new crime which may arise is obviously one very dangerous to political liberty, as it greatly enlarges the power of the Crown to oppress political opponents, but in modern days it has its convenience in facilitating the punishment of persons committing crimes for the punishment of which in England a new Act of Parliament may be necessary. The localization in England of crime, and the procedure for punishing it, differ largely from the view taken in France and most European countries. The French theory is that a Frenchman owes allegiance to the French State, and commits a breach of that allegiance whenever he commits a crime against French law, even although he is not at the time within French territory. And in modern days this theory has been extended so as to allow the French courts to punish Frenchmen for crimes committed in foreign countries.

The principle of the French law, though not expressly recognized in England, must be invoked to justify two departures from the English principle (1) as regards offences on the high seas, and (2) as regards certain limited offences committed outside the United Kingdom. In early days offences committed by Englishmen on the high seas were punished by the Lord High Admiral, and he encroached so much on the ordinary courts as to render it necessary to pass an Act in Richard II.'s reign (15 Rich. II. st. 2, c. 3) to restrain him.

*Offences on the high seas.*

In the time of Henry VIII. (28 Hen. VIII. c. 15) an Act was passed stating that as the admiral tried persons according to the course of the civil law, they could not be convicted unless either they confessed or they or the witnesses were submitted to torture, and that therefore it was expedient to try the offences according to the course of the common law. Under that Act a special commission of Oyer and Terminer was issued to try these offences at the Old Bailey, and English law was satisfied by permitting the indictment to state that the offence was committed on board a ship on the high seas, to wit in the county of Middlesex. Since 1861 these special commissions have

been rendered unnecessary by the provision that all offences committed on the high seas may be tried as if they had been committed in England. As regards offences on land, it was found necessary as early as the reign of Henry VIII. to provide for the trial in England of treasons and murders committed on land outside England; this was largely due to the constant presence in France of the king and many of his nobles and knights. The latest legislation on the subject was in 1861 (24 & 25 Vict. c. 100, s. 9), and any murder or manslaughter committed on land out of the United Kingdom, whether within the King's dominions or without, and whether the person killed were a subject of His Majesty or not, may be dealt with in all respects as if it were committed in England. The jurisdiction has been extended to a few other cases such as slave trade, bigamy, perjury committed with reference to an English court, and offences connected with explosives. But these offences must be committed on land and not on board a foreign ship, because if a man takes service on board a foreign ship he is treated for the time as being a member of the foreign State to which that ship belongs. The principle has been also extended to misdemeanours (but not felonies) committed by public officers in colonies and elsewhere, whether within or without the British dominions. Thus a Governor or an Inferior Officer of a colony, if appointed by the British Government, may be prosecuted for any misdemeanour committed by him by virtue of his office in the colony; and cases have happened where governors have been so prosecuted, such, for instance, as the case of General Picton at the beginning of the 19th century, and of Governor Eyre of Jamaica in 1865.

**Offences committed on land outside England.**

**Misdemeanours committed by public officers in colonies.**

There are a few exceptional courts with criminal jurisdiction. The Court of Chivalry, which used to punish offences committed within military lines outside the kingdom, has long disappeared. The Military Courts for trying members of the navy and army for offences committed against naval and military law have been already referred to. The naval courts can only try members in actual service on board a ship. The military courts can only try persons who are actually members of the army at the time, and their authority is annually renewed by Parliament, in consequence of the jealousy still felt against the trial of any man except by the ordinary courts of law. These courts can try in any part of the world, and whenever the forces are in active service can try followers of the camp as if they were actual members of the forces. (See articles on MILITARY LAW and MARTIAL LAW.)

**Ecclesiastical Courts.**

The Ecclesiastical Courts, which were formerly very powerful in England, and punished persons for various offences, such as perjury, swearing, and sexual offences, have now almost fallen into desuetude. Their authority over Protestant dissenters from the Established Church was taken away by statute; their authority over lay members of the Church of England has disappeared by disuse. Occasionally suits are instituted in them against the clergy for offences either against morality or against doctrine or ritual. In these cases their sentences are enforced by penalties, such as suspended deprivation of their benefice, or by imprisonment, which has replaced the old punishment of excommunication.

Reference has been made in various places to the criminal law which prevails on the Continent. The English system prevails in most of the States which form the United States of America. It prevails also, with a few exceptions, in the Colonies of the British Empire; but the manner in which it has been adapted to the requirements of a backward country is best exemplified in the system of law which obtains in India, the greatest dependency of the Empire. In the first place both the substantive and the adjective criminal law have been codified. The Indian Penal Code came into force in 1860, and the Indian Code of Criminal Procedure, enacted in 1882, has been somewhat modified by an amending Act of 1898. As regards all criminal law as administered throughout British India, they have taken the place of an older criminal system, which was based partly on Mahommedan law, partly on usage and custom, partly on principles imported from England. Great delays and considerable injustice were formerly caused by the want of unity in judicial organization. Now, one set of courts has been established throughout the country, composed of well-paid, well-educated judges, most of the higher judicial appointments being held by Englishmen; all those who hold subordinate judicial posts at the same time are subjected to a combined system of appeal and revision. The arrangement of the Indian Penal Code is natural as well as logical; its basis is the law of England freed from technicalities, whilst certain modifications are introduced to meet the exigencies of a country such as British India. It opens with a chapter of general explanations, and interpretations of the terms used throughout the Code. It then describes the various punishments to which offenders are liable; follows with a list of the exceptions regarding criminal responsibility under which a person who otherwise would be liable to punishment is exempted from the penal consequences of his act, such as offences committed by children, by accident or misfortune without any criminal intention, offences committed by lunatics, offences committed in the exercise of the right of private defence. It may be worth while to add, as an innovation on English law, that an act which results in harm so slight that no person of ordinary sense and temper would complain of such harm is not considered an offence under the Code. Then follows a chapter on Abetment, in other words, the instigation of a person to do a wrongful act. The next chapters deal with offences against the public, including the State, the army and navy, public tranquillity, public servants, contempts of the lawful authority of public servants, perjury; offences relating to coin and Government stamps, to weights and measures; offences affecting the public health, safety, convenience, decency, and morals; offences relating to religion; and offences relating to the human body, from murder down to the infliction of any hurt. The Code then passes on to offences against property; offences relating to forgery, including trade marks, criminal breach of contracts for service; offences relating to marriage, defamation, criminal intimidation, insult, and annoyance. Under this last head is included an attempt to cause a person to do anything which that person is not legally bound to do, by inducing him to believe that he would otherwise become subject to Divine displeasure. The last chapter deals with attempts to commit offences punishable by the Code with transportation or imprisonment, and the punishment is limited to one-half of the longest term provided for the offence had it been carried out.

**Indian Penal Code.**

One peculiarity of the Penal Code which has proved eminently successful and been imitated by other Codes, lies in the system of illustration of the offence declared in every section by a brief statement of some concrete case. For instance, as illustration of the offence of an attempt to commit an offence the following examples are given:—

I. "A. makes an attempt to steal some jewels by breaking open a box, and finds on opening the box there is no jewel in it. He has done an act towards the commission of theft, and therefore is guilty under this section.

II. "A. makes an attempt to pick the pocket of Z. by thrusting his hand into Z.'s pocket. A. fails in the attempt in consequence

of Z. having nothing in his pocket. A. is guilty under this section."

Passing on to the system of criminal procedure which is set forth in detail in the Code of Criminal Procedure as amended in 1898, it is no doubt modelled on the English system, but with considerable modifications. The principal steps are—(1) arrest by the police and inquiries by the police; (2) the issue of summons or warrant by the magistrate; (3) the mode of procedure before the magistrate, who may either try the accused himself or commit him to the Sessions or the High Court, according to the importance of the case; (4) procedure before the Court of Session; (5) appeals, reference and revision by the High Court.

***Indian Code of Criminal Procedure.***

Elaborate provision is made for the prevention of offences, as regards security for keeping the peace and for good behaviour, the dispersion of unlawful assemblies, the suppression of nuisances, disputes as to immovable property, which in all Oriental countries constitute one of the most frequent causes of a breach of the peace.

Ample provision is thus made for the prevention of offences, and the Code next deals with the mode of prosecution of offences actually committed.

As a general rule, every offence is inquired into and tried by the court within the local limits of whose jurisdiction it was committed. Differing from the practice of Continental countries, all offences, even attempts, may be prosecuted after any lapse of time. As in England, there is no statutory limitation to a criminal offence.

A simple procedure is provided for what are called summons cases, as distinguished from warrant cases—the first being offences for which a police officer may arrest without warrant, the second being offences where he must have a warrant, or, in other words, minor offences and important offences. In summons cases no formal charge need be framed. The magistrate tells the accused the particulars of the offence charged: if he admits his guilt, he is convicted; if he does not, evidence is taken, and a finding is given in accordance with the facts as proved. When the complaint is frivolous or vexatious, the magistrate has the power to fine the complainant. The Code gives power of criminal appeal which goes much farther than the system in England.

In cases tried by a jury, no appeal lies as to matters of fact, but it is allowed as to matters of law; in other cases, criminal appeal is admitted on matters of law and fact.

In addition to the system of appeal, the superior courts are entrusted with a power of revision, which is maintained automatically by the periodical transmission to the High Courts of calendars and statements of all cases tried by the inferior courts; and at the same time, whenever the High Court thinks fit, it can call for the record of any trial and pass such orders as it deems right. All sentences of death must be confirmed by the High Court. No appeal lies against an acquittal in any criminal case. This system of appeal, superintendence, and revision would be totally inapplicable to England, but it has proved eminently successful as applied to the present social condition of the inhabitants of India. The appeals keep the judges up to their work, revision corrects all grave mistakes, superintendence is necessary as a kind of discipline over the conduct of judges, who are not subjected, as in England, to the criticism of enlightened public opinion.

The French Penal Code and Code of Criminal Procedure are still substantially the model of all systems of Continental criminal law. They were promulgated in 1811 by Napoleon I., and although he called in the aid of the greatest French jurists, he guided, and occasionally even revised, their labours. The French Codes have been amended by later Continental Codes, and more especially the Italian Penal Codes. All Codes have an opening chapter where the general principles of criminal law in its practical application are enunciated, such as, for instance, the rules that—(1) no person is liable to punishment for any act not expressly declared to be an offence; (2) no person can be punished for an act which by virtue of a subsequent law is declared not to be an offence; (3) whoever commits an offence within the kingdom is tried and punished according to the criminal law of the kingdom, and by the tribunals created for the administration of justice, to the exclusion of special tribunals created for temporary purposes. This rule really lays down that no citizen can be deprived of his own judges when he is accused of a criminal offence. (4) A citizen, although he may have been tried in a foreign country for an offence committed within the kingdom, can be retried according to the law of the kingdom; (5) extradition only applies to foreigners, not to citizens. The preliminary chapter is followed by the classification of offences according to the importance of the punishments the law assigns to them. The lowest degree of offence is denominated "contravention." It applies mainly to the pettiest offences, or to infractions of police regulations, and can be punished by fine or by imprisonment under a week, or by both fine and imprisonment, limited to a week. Next comes the "*délit*," which includes all offences punished by imprisonment over a week and under five years. Then, finally, we arrive at the "crime," the highest form of offence in French Criminal Law. It includes all offences subject to a more severe sentence than the punishment assigned to a *délit*. All cases are held to be crimes where death, life-imprisonment with or without hard labour, deportation out of the kingdom, detention or seclusion in a fortress or other expressly assigned place, are the punishments mentioned by the law. A certain number of explanatory definitions follow, of which the most important concern *attempts* to commit offences, and in "crimes" they are punishable if the execution of the attempt was only prevented by circumstances beyond the will of the offender, whilst in "*délits*" an attempt is not punishable as an offence unless the law specially provides that it should be punished. As regards "contraventions," attempts not carried out are not held to be offences at all. Accomplices are generally subject to the same punishment as the principal. Old offenders (*récidivistes*) are subject to severer punishments. The usual exceptions as regards responsibility for crime, such as madness and extreme youth and *force majeure*, are to be found in all Codes. The excuse of youth extends to all offenders under the age of sixteen, when the tribunal decides whether the offender has acted without "discernment," and acquits where the discernment is not found, whilst one-half of the usual punishment is inflicted where discernment is found. Foreign Codes differ from the English law in allowing the injured party to claim damages in the criminal suit, appearing as *partie civile*. On another question there is a wide divergence on the Continent from English law. According to the law of England there is no prescription in criminal law. An offender is always liable to punishment whatever time may have elapsed since the committal of the offence. On the Continent the limitation of a judgment and sentence for a crime is twenty years; five years for a *délit*, and for a contravention two years. No proceedings can be taken as regards a crime after a lapse of ten years, whilst as regards a *délit* the limit is three years, and two years for a contravention. There are three main differences between English criminal procedure and Continental criminal procedure.

***Non-British criminal procedure.***

1. A criminal prosecution directed on Continental

criminal procedure at once passes into the hands of the State as an infringement of law which must be repressed, on the ground that the whole community bases its security on obedience to law. In England the repression of all minor crime is left to the injured party.

2. In England every criminal proceeding from beginning to end is, and has always been, public, whilst on the Continent, with rare exceptions, all preliminary proceedings in a criminal charge are secret. The public system is called accusatory, the secret system is called inquisitorial.

Outside English-speaking countries this secret investigation continues more or less. But of the two systems, accusatory or inquisitorial—the first meaning the right of the accused to defend himself, the second meaning the right of the State to examine any legal offence in private in order to ensure the safety of society,—the accusatory is gaining ground in every country. In English-speaking countries it is an established law that an accused person should have the right of publicity of the proceedings and the right to defend himself by counsel and by witnesses. On the Continent the inquisitorial system is gradually being abandoned. Perhaps the best Code of Criminal Procedure in Europe is that promulgated in Austria in 1873. It followed a fundamental law of the Empire which laid down *inter alia* that all legal proceedings, civil or criminal, should be oral and public, and that the accusatory system in criminal cases should be adopted. Germany followed this example. Italy, Holland, Switzerland, and Spain have followed Austria and Germany as regards the preliminary investigation; Italy and Belgium have surrounded the accused with guarantees against arbitrary confinement before trial; Holland has conferred upon the accused the right of seeing the adverse testimony and of being confronted with the witnesses, and, further, has formally insisted that no insidious questions, such as questions assuming a fact as true which is not known to be true, should be allowed. Other countries still remain on the old lines. But everywhere, whether reform has actually been accomplished or not, there is a demand for even-handed justice, and a growing conviction that the accused should have all his rights, now that society is no longer in danger from undiscovered criminals and unpunished crime. Even in France, the champion of the inquisitorial system, a change is rapidly being made. Up to 1897 secrecy was imposed invariably in the preliminary investigation of crime, and was held necessary for the discovery and punishment of the offender. The "Loi de l'Instruction Contradictoire," December 8, 1897, however, was a long step towards complete justice in the treatment of the accused in the preliminary inquiry. The main reform is that the accused, after he had once appeared before the judge and a formal charge has been made against him, is entitled to the assistance of counsel, either chosen by himself or assigned to him if he is poor. If he is in prison, he is allowed to communicate freely with his counsel, who is entitled to see all the proceedings, and in every appearance before the judge his counsel accompanies him. There are, however, certain limitations. The counsel cannot address the judge without leave, which may be refused, nor can he insist on any proceeding he thinks necessary in his client's interest. He can only solicit. He has no right to be present at the examination of witnesses, who continue to be interrogated by the judge alone and not in the presence of the accused; but he must receive twenty-four hours' notice of every appearance of the accused, and he is entitled to be present whenever his client, after the first formal appearance, comes before the judge. In England, as already pointed out, although the prosecution is in the name of the Crown, and although a public prosecutor has been appointed, still as a rule it is conducted by the person injured as the person injured, or by the police.

3. In England the single-judge system is universal, save in appeal; on the Continent plurality of judges is insisted upon, save in the most trivial cases, where the punishment is insignificant. The Public Prosecutor's Department is yet in embryo in England, whilst in most countries of the Continent the whole machinery for the prevention, investigation, and punishment of crime, is conducted by what is called the *Parquet*, which represents society as a collective unit and not the individual injured. The head of the whole Parquet in France is the *Procureur-Général*, who holds equal rank with the members of the Supreme Court. Under him there are Procureurs-Généraux attached to each of the Courts of Appeal, of which in France there are twenty-six, and under each of these subordinate Procureurs there are Procureurs (prosecutors) of a lesser degree. The next stage to the Parquet is the Juge d'Instruction, who corresponds to the English magistrate, and is the most formidable personage in the whole system of French criminal law. He can detain and accuse a person in prison, can send for him at any time and ask him such questions as he pleases.

After the first examination the prisoner is entitled, in most Continental countries, to the assistance of counsel, but the powers of counsel are so limited that the Juge d'Instruction has a complete discretionary power regarding the investigation of the case. The natural consequence of this procedure is that the preliminary investigation really decides the ultimate result, and the final trial becomes more or less a solemn form.

The single-judge system, applied to important matters, prevails only in English-speaking countries, or where English influence is dominant. On the Continent a plurality of judges is deemed essential to the administration of sound justice. This rule was probably made at a time when judges could never be allowed to sit alone for fear of the influence of the rich and powerful, the possibility of corruption, and the danger that a judge sitting alone would decide questions sometimes according to his convenience. Experience has shown in England and in all Greater Britain that the concentration of responsibility, which is the basis of the single-judge system, is preferable to a multiplicity of judges, none of whom feel the same duty to the case before them. Financial considerations also come into the question. It is of paramount importance that a judge should be sufficiently well paid to ensure his absolute independence from every point of view. The following comparative tables of judicial salaries in England and France speak for themselves:—

*England*—

| | | |
|---|---|---|
| | Lord Chancellor | £10,000 |
| | Lord Chief Justice of England | 8,000 |
| (4) | Lords of Appeal, each | 6,000 |
| | Master of the Rolls | 6,000 |
| (5) | Lord Justices, each | 5,000 |
| (23) | Judges of the High Court, each | 5,000 |
| | Recorder of London | 4,000 |
| | Common Serjeant | 3,000 |
| | Assistant Judges, each | 1,500 |
| | Judge (City of London Court) | 2,400 |
| (56) | County Court Judges, each | 1,500 |
| (11) | Metropolitan County Court Judges, each | 1,500 |
| | Other Metropolitan Police Magistrates, each | 1,500 |
| | Bow Street Police Magistrate | 1,800 |

*France*—

| | | |
|---|---|---|
| | President of the Court of Cassation | 1,200 |
| (3) | Presidents of Chambers of the Court of Cassation, each | 1,000 |

| | |
|---|---|
| (45) Judges of the Court of Cassation, each | £720 |
| (1) President (at Paris) of the Court of Appeal | 1,000 |
| (25) Presidents of other Courts of Appeal, each | 720 |
| (59) Presidents of Chambers of Courts of Appeal— | |
| (9) at Paris, each | 550 |
| (50) in Provinces, each | 400 |
| (359) Presidents of Tribunals of 1st Instance— | |
| (1) at Paris | 800 |
| (15) 1st Class, each | 400 |
| (76) 2nd Class " | 280 |
| (267) 3rd Class " | 200 |
| (633) Judges— | |
| (48) Paris, each | 320 |
| (77) 1st Class, each | 240 |
| (175) 2nd Class " | 160 |
| (335) 3rd Class " | 120 |

*Tribunals of the Juge de Paix.*

| | |
|---|---|
| Judges number 2872— | |
| 20 receive, each | 320 |
| 43 " " | 200 |
| 754 " " salaries varying from | 140 to 84 |
| 2055 " " | 72 |

*Ministère Publique* (*Public Prosecutor's Department*).

| | |
|---|---|
| Chief Public Prosecutor | 1,200 |
| His Advocate-General in Cour de Cassation | 720 |
| (26) Public Prosecutors in Court of Appeal— | |
| (1) Paris | 1,000 |
| (25) In Provinces, each | 720 |

**Crimmitschau,** a town of Germany, on the Pleisse, 8 miles north-north-west of the town and in the circle of Zwickau, kingdom of Saxony; on the Leipzig-Hof Railway. There are *real*, commercial, and technical schools, and over 100 spinning mills and woollen cloth factories, employing between 5000 and 6000 workmen. Population (1890), 23,068; (1900), 22,840.

**Cripple Creek,** a mining city of El Paso county, Colorado, U.S.A., situated near the centre of the state, in 38° 45′ N. lat. and 105° 11′ W. long., in the mountains west of Pike's Peak, at an altitude of 9500 feet. It has two railways, the Florence and Cripple Creek, making connexion with Pueblo, and the Midland Terminal, a branch of the Colorado Midland, connecting with Colorado Springs. It is the richest gold mining camp in the United States. Gold was first discovered in 1891, and in 1897 the production exceeded $10,000,000. The sources of the gold are placers, veins, and the country rock. The ores consist of free gold, not only in placers but in veins and country rock, and tellurides and auriferous iron pyrites. They differ greatly in value, ranging from $20 up to several thousand dollars per ton. Population (1900), 10,147.

**Crispi, Francesco** (1819–1901), Italian statesman, was born at Ribéra in Sicily, October 4, 1819. In 1846 he established himself as advocate at Naples. On the outbreak of the Sicilian Revolution at Palermo (January 12, 1848) he hastened to the island and took an active part in guiding the insurrection. Upon the restoration of the Bourbon Government (May 15, 1849) he was excluded from the amnesty and compelled to flee to Piedmont. Here he unsuccessfully applied for a situation as communal secretary of Verolengo, and eked out a penurious existence by journalism. Implicated in the Mazzinian conspiracy at Milan (February 6, 1853), he was expelled from Piedmont, and obliged to take refuge at Malta, whence he fled to Paris. Expelled from France, he joined Mazzini in London, and continued to conspire for the redemption of Italy. On June 15, 1859, he returned to Italy after publishing a letter repudiating the aggrandizement of Piedmont, and proclaiming himself a Republican and a partisan of national unity. Twice in that year he went the round of the Sicilian cities in disguise, and prepared the insurrectionary movement of 1860. Upon his return to Genoa he organized, with Bertani, Bixio, Medici, and Garibaldi, the expedition of the Thousand, and overcoming by a stratagem the hesitation of Garibaldi, secured the departure of the expedition on May 5, 1860. Disembarking at Marsala on the 11th, Crispi on the 13th, at Salemi, drew up the proclamation whereby Garibaldi assumed the Dictatorship of Sicily, with the programme: "Italy and Victor Emmanuel." After the fall of Palermo, Crispi was appointed Minister of the Interior and of Finance in the Sicilian provisional government, but was shortly afterwards obliged to resign on account of the struggle between Garibaldi and the emissaries of Cavour with regard to the question of immediate annexation. Appointed secretary to Garibaldi, Crispi secured the resignation of Depretis, whom Garibaldi had appointed Pro-Dictator, and would have continued his fierce opposition to Cavour at Naples, where he had been placed by Garibaldi in the Foreign Office, had not the advent of the Italian regular troops and the annexation of the Two Sicilies to Italy brought about Garibaldi's withdrawal to Caprera, and Crispi's own resignation. Entering Parliament in 1861 as deputy of the Extreme Left for Castelvetrano, Crispi acquired the reputation of being the most aggressive and most impetuous member of the Republican party. In 1864, however, he made at the Chamber a Monarchical profession of faith, in the famous phrase afterwards repeated in his letter to Mazzini: "The Monarchy unites us; the Republic would divide us." In 1866 he refused to enter the Ricasoli Cabinet; in 1867 he worked to impede the Garibaldian invasion of the Papal States, foreseeing the French occupation of Rome and the disaster of Mentana. By methods of the same character as those subsequently employed against himself by Cavallotti, he carried on the violent agitation known as the Lobbia affair, in which sundry Conservative deputies were, on insufficient grounds, accused of corruption. On the outbreak of the Franco-German War he worked energetically to impede the projected alliance with France, and to drive the Lanza Cabinet to Rome. The death of Ratazzi in 1873 induced Crispi's friends to put forward his candidature to the leadership of the Left; but Crispi, anxious to reassure the Crown, secured the election of Depretis. After the advent of the Left he was elected (November 1876) President of the Chamber. During the autumn of 1877 he went to London, Paris, and Berlin on a confidential mission, establishing cordial personal relationships with Gladstone, Granville, and other English statesmen, and with Bismarck.

In December 1877 he replaced Nicotera as Minister of the Interior in the Depretis Cabinet, his short term of office (70 days) being signalized by a series of important events. On January 9, 1878, the death of Victor Emmanuel and the accession of King Humbert enabled Crispi to secure the formal establishment of a unitary Monarchy, the new monarch taking the title of Humbert I., instead of Humbert IV. of Savoy. The remains of Victor Emmanuel were interred in the Pantheon, instead of being transported to the Savoy Mausoleum at Superga. On February 9, 1879, the death of Pius IX. necessitated the first Conclave held after the unification of Italy. Crispi, helped by Mancini

and Cardinal Pecci (afterwards Leo XIII.), persuaded the Sacred College to hold the Conclave in Rome, and prorogued the Chamber lest any untoward manifestation should mar the solemnity of the event. The statesmanlike qualities displayed on this occasion were unavailing to avert the storm of indignation conjured up by Crispi's opponents in connexion with a charge of bigamy incapable of legal proof. Crispi was compelled to resign office, although the judicial authorities upheld the invalidity of his early marriage, contracted at Malta in 1853, and ratified his subsequent union with Signora Barbagallo. For nine years Crispi remained politically under a cloud, but in 1887 returned to office as Minister of the Interior in the Depretis Cabinet, succeeding to the Premiership upon the death of Depretis (July 29, 1887).

One of his first acts as Premier was a visit to Bismarck, whom he desired to consult upon the working of the Triple Alliance. Basing his foreign policy upon the alliance, as supplemented by the naval *entente* with Great Britain negotiated by his predecessor, Count Robilant, Crispi assumed a resolute attitude towards France, breaking off the prolonged and unfruitful negotiations for a new Franco-Italian commercial treaty, and refusing the French invitation to organize an Italian section at the Paris Exhibition of 1889. At home Crispi secured the adoption of the Sanitary and Commercial Codes, and reformed the administration of justice. Forsaken by his Radical friends, Crispi governed with the help of the Right, until, on January 31, 1891, an intemperate allusion to the former policy of the Conservative party led to his overthrow. In December 1893 the impotence of the Giolitti Cabinet to restore public order, then menaced by disturbances in Sicily and in Lunigiana, gave rise to a general demand that Crispi should return to power. Upon resuming office he vigorously suppressed the disorders, and lent sturdy support to the energetic remedies adopted by Sonnino, Minister of Finance, to save Italian credit, which had been severely shaken by the bank and financial crises of 1892–1893. Crispi's uncompromising suppression of disorder, and his refusal to abandon either the Triple Alliance or the Eritrean Colony, or to forsake his colleague Sonnino, caused a breach between him and the Radical leader Cavallotti. Cavallotti then began against him a pitiless campaign of defamation. An unsuccessful attempt upon Crispi's life by the anarchist Lega brought a momentary truce, but Cavallotti's attacks were soon renewed more fiercely than ever. They produced so little effect that the general election of 1895 gave Crispi a huge majority, but, a year later, the defeat of the Italian army at Adowa in Abyssinia brought about his resignation. The ensuing Rudini Cabinet lent itself to Cavallotti's campaign, and at the end of 1897 the judicial authorities applied to the Chamber for permission to prosecute Crispi for embezzlement. A parliamentary Commission, appointed to inquire into the charges against him, discovered only that Crispi, on assuming office in 1893, had found the Secret Service coffers empty, and had borrowed from a State bank the sum of £12,000 for Secret Service, repaying it with the monthly instalments granted in regular course by the Treasury. The Commission, considering this proceeding irregular, proposed, and the Chamber adopted, a vote of censure, but refused to authorize a prosecution. Crispi resigned his seat in Parliament, but was re-elected by an overwhelming majority in April 1898 by his Palermo constituents. For some time he took little part in active politics, chiefly on account of his growing blindness. A successful operation for cataract restored his eyesight in June 1900, and notwithstanding his 81 years he resumed to some extent his former political activity. Soon afterwards, however, his health began to give way permanently, and he died at Naples on the 12th of August 1901.

FRANCESCO CRISPI.
*(From a Photograph by Giacomo Brogi, Florence.)*

The importance of Crispi in Italian public life depended less upon the many reforms accomplished under his administrations than upon his intense patriotism, remarkable fibre, and capacity for administering to his fellow-countrymen the political tonic of which they stood in constant need. In regard to foreign politics he greatly contributed to raise Italian prestige and to dispel the reputation for untrustworthiness and vacillation acquired by many of his predecessors. (H. W. S.)

**Croatia - Slavonia** (Horvát - Szlavonország), an autonomous province (Borderland) of Hungary. Area, 16,417 square miles, with 2,416,304 inhabitants in 1900. At the head of the Government stands the Banus, appointed by the king, with counter-signature of the Hungarian Prime Minister. The provincial Diet (Croatia-Slavonian-Dalmatian National Assembly) consists (*a*) of elected deputies, (*b*) of personal. voters, whose number, however, cannot exceed half of that of the elected deputies. The National Assembly delegates out of its midst 40 deputies to the House of Commons and 3 deputies to the House of Magnates of the Hungarian Parliament, who participate in the discussion of the affairs which are common to Hungary and Croatia-Slavonia. The Croatian Minister, without portfolio, is a member of the Hungarian Government, who countersigns every act of importance of the provincial Government of Croatia-Slavonia. In the eastern part of the land, especially on the plain extending between the Danube, Dráva, and Száva, agriculture is largely carried on. The chief products of 1900 were 3·0 millions metric centners of wheat, 3·6 mill. metr. cent. of potatoes, and 4·7 mill. metr. cent. of maize. The mountainous portion of the country is wooded, and on the plains are extensive forests. Above one-third (1,511,779 hectares = 35·74 per cent.) of the cultivable territory is covered by forests, whereof the public treasury possesses 300·280 hectares, of a value of 58·9 million crowns. Of the grain produced, wheat, potatoes, and maize are

the most important. Excepting Zágráb (Agram), the rapidly rising capital of Croatia-Slavonia, and its surroundings, the greatest traffic is in the regions near the Danube and the frontier passes towards Bosnia.

**Croix,** or **Croix Wasequehal,** a town of France, in the department of Nord, arrondissement of Lille, 5 miles north-east of Lille and 2 miles south-west of Roubaix, with station on railway to Courtrai. The town is situated near the Marcq, an affluent of the Deule, and is practically a suburb of Roubaix. Port traffic (1899), 71,145 tons. Population (1881), 3260; (1896), 13,895; (1901), 15,933.

**Croll, James** (1821–1890), Scottish man of science, was born of a peasant family at Little Whitefield, in Perthshire, 2nd January 1821. He was regarded as an unpromising boy, but a trifling circumstance aroused a passion for reading, and he made great progress in self-education. Debarred by ill-health from manual labour, he became successively a shopkeeper and an insurance agent, and in 1859 was made keeper of the Andersonian Museum at Glasgow, a humble appointment, which, however, gave him what he most required. In 1857, being deeply impressed by the metaphysics of Jonathan Edwards, he had published an anonymous volume entitled *The Philosophy of Theism*; but his connexion with the Museum induced him to take up physical science, and in 1864 he wrote his celebrated essay "On the Physical Causes of the Changes of Climate during the Glacial Epoch." This led to his receiving an appointment on the Scottish Geological Survey in 1867. In 1875 he summed up his researches upon the ancient condition of the earth in his *Climate and Time*, in which he contends that terrestrial revolutions are due in a measure to cosmical causes. This theory excited warm controversy. Croll's replies to his opponents are collected in his *Climate and Cosmology* (1885). He had been compelled by ill-health to withdraw from the public service in 1881; yet, working under the greatest difficulties, and harassed by the miserable inadequacy of his retiring pension, he managed to produce *Stellar Evolution*, discussing, among other things, the age of the sun, in 1889; and *The Philosophical Basis of Evolution*, partly a critique of Herbert Spencer's philosophy, in 1890. He died on 15th December 1890. The soundness of Croll's theories remains a subject of controversy, but his character as a scientific worker under the greatest discouragements was nothing less than heroic. His life, prefaced by an unfinished autobiography, was written by Mr J. C. Irons in 1896. (R. G.)

**Cromarty.** See Ross.

**Cromer**, a parish and fashionable watering-place in the northern parliamentary division of Norfolk, England, 22 miles north of Norwich by rail. Standing on cliffs of considerable elevation, the town has repeatedly suffered from ravages of the sea. In 1894 a wall and esplanade were built at the bottom of the East Cliffs, and these are being extended to the west. A pier, 183 yards long, is to be constructed at a cost of £11,000. A water reservoir to hold 600,000 gallons was finished in 1896. There are a town-hall, a cottage hospital, and a lecture hall. On a site of three acres stands the Convalescent Home of the Norfolk and Norwich Hospital. There is an excellent golf course. There are herring, cod, lobster, and crab fisheries. Area of urban district, 938 acres. Population (1881), 1597; (1901), 3776.

**Cromer, Evelyn Baring,** 1st Earl (1841——), British statesman and diplomatist, was born on the 26th February 1841, the ninth son of Henry Baring, M.P., by Cecilia Anne, eldest daughter of Admiral Windham of Felbrigge Hall, Norfolk. Having joined the Royal Artillery in 1858, he was appointed in 1861 A.D.C. to Sir Henry Storks, High Commissioner of the Ionian Islands, and acted as secretary to the same chief during the inquiry into the Jamaica outbreak in 1865. Gazetted captain in 1870, he went in 1872 as private secretary to his cousin Lord Northbrook, Viceroy of India, where he remained until 1876, when he became major, received the C.S.I., and was appointed British Commissioner of the Egyptian Public Debt Office. Up to this period Major Baring had given no unusual signs of promise, and the appointment of a comparatively untried major of artillery as the British representative on a Financial Board composed of representatives of all the Great Powers was considered a bold one. Within a very short time it was recognized that the Englishman, though keeping himself carefully in the background, was unmistakably the predominant factor on the Board. He was mainly responsible for the searching report of the Commission of Inquiry that had been instituted into the financial methods of the Khedive Ismail; and when that able and unscrupulous Oriental had to submit to an enforced abdication, it was Major Baring who became the British Controller-General and practical director of the Dual Control. Had he remained in Egypt, the whole course of Egyptian history might have been altered, but his services were deemed more necessary in India, and under Lord Ripon he became Financial Member of Council in June 1880. He remained there till 1883, leaving an unmistakable mark on the Indian financial system, and then, having been rewarded by the K.C.S.I., he was appointed British Agent and Consul-General in Egypt and a Minister Plenipotentiary in the Diplomatic Service.

Sir Evelyn Baring was at that time only a man of forty-two, who had gained a reputation for considerable financial ability, combined with an abruptness of manner and a certain autocracy of demeanour which, it was feared, would impede his success in a position which required considerable tact and diplomacy. It was a friendly colleague who wrote—

> The virtues of Patience are known,
> But I think that, when put to the touch,
> The people of Egypt will own, with a groan,
> There's an Evil in Baring too much.

When he arrived in Cairo in 1883 he found the administration of the country almost non-existent. Ismail had ruled with all the vices, but also with all the advantages, of autocracy. Disorder in the finances, brutality towards the people, had been combined with public tranquillity and the outer semblance of civilization. Order, at least, reigned from the Equator to the Mediterranean, and such trivial military disturbances as had occurred had been of Ismail's own devising and for his own purposes. Tewfik, who had succeeded him, had neither the inclination nor character to be a despot. Within three years his government had been all but overthrown, and he was only Khedive by the grace of British bayonets. Government by bayonets was not in accord with the views of the House of Commons, yet Ismail's government by the kourbash could not be restored. The British Government, under Mr Gladstone, desired to establish in Egypt a sort of Constitutional Government; and as there existed no single element of a constitution, they had sent out Lord Dufferin to frame one. That gifted nobleman, in the delightful lucidity of his picturesque report, left nothing to be desired except the material necessary to convert the flowing periods into political entities. In the absence of that, the constitution was still-born, and Sir Evelyn Baring arrived to find, not indeed a clean slate, but a worn-out papyrus, disfigured by the efforts of centuries to describe in hieroglyph a method of rule for a docile people.

From that date the history of Sir Evelyn Baring, who became Baron Cromer in 1892, G.C.B. in 1895, Viscount in 1897, and Earl in 1901, is the history of Egypt, and requires the barest mention of its salient points here. From the outset he realized that the task he had to perform could only be effected piecemeal and in detail, and his very first measure was one which, though severely criticized at the time, has been justified by events, and which in any case showed that he shirked no responsibility and was capable of adopting heroic methods. He temporarily abandoned that portion of the territory over which Egypt held only a nominal sway, already challenged by the Mahdi, and set himself to work to reorganize the remainder. That portion, too, he attacked in detail. The very first essential was to regulate the financial situation; and in Egypt, where the entire revenue is based on the production of the soil, irrigation was of the first importance. With the assistance of Sir Colin Scott Moncrieff, in the Public Works Department, and Sir Edgar Vincent, as Financial Adviser, these two great departments were practically put in order before he gave more than superficial attention to the rest. The Ministry of Justice was the next department seriously taken in hand, with the assistance of Sir John Scott, while the army had been reformed under Sir Evelyn Wood, who was succeeded by Sir Francis Grenfell. Education, the Ministry of the Interior, and gradually every other department, came to be reorganized, or, more correctly speaking, formed, under Lord Cromer's carefully persistent direction, until it may be said to-day that the Egyptian administration can safely challenge comparison with that of any other state. In the meantime the rule of the Mahdi and his successor, Abdulla Khalifa, in the temporarily abandoned provinces of the Sudan, had been weakened by internal dissensions; the Italians from Massawa, the Belgians from the Congo State, and the French from their West African possessions, had gradually approached nearer to the valley of the Nile; and the moment had arrived at which Egypt must decide either to recover her position at Khartum or allow that important centre to fall into hands hostile to Great Britain and her position in Egypt. Lord Cromer was as quick to recognize the moment for action and to act as he had fifteen years earlier been prompt to recognize the necessity of abstention. In March–September 1896 the first advance was made to Dongola under the Sirdar, Sir H. (now Lord) Kitchener; between July 1897 and April 1898 the advance was pushed forward to the Atbara; and on September 2, 1898, the battle of Omdurman finally crushed the power of the Khalifa and restored the Sudan to the rule of Egypt and Great Britain. To have effected this in the face of the greatest difficulties,—political, national, and international,—and at the same time to have raised the credit of the country from a condition of bankruptcy to an equality with that of the first European Powers, entitles Lord Cromer to a very high place among the greatest administrators that the British Empire has produced. Lord Cromer married in 1876 Ethel Stanley, daughter of Sir Rowland Stanley Errington, eleventh baronet, but was left a widower with two sons in 1898; and in 1901 he married Lady Katherine Thynne, daughter of the fourth Marquess of Bath.

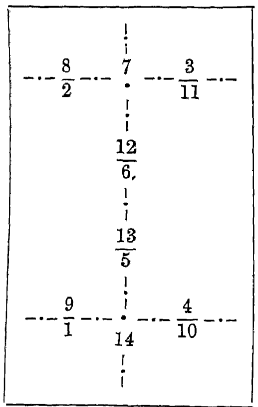
**Crompton,** a township in the Prestwich division of Lancashire, England, $2\frac{1}{2}$ miles north of Oldham. Since 1894 it has been governed by an urban district council. At Shaw, a large village included within it, is a station on the Lancashire and Yorkshire Railway. Population (1891), 12,901; (1901), 13,427.

**Crookes, Sir William,** (1832——), English chemist and physicist, was born in London on 17th June 1832, and studied chemistry under Hofmann at the Royal College of Chemistry. In 1861, while conducting a spectroscopic examination of the residue left in the manufacture of sulphuric acid, he observed a bright green line which had not been noticed previously, and by following up the indication thus given he succeeded in isolating a new metal, thallium, a specimen of which was shown in public for the first time at the Exhibition of 1861. During the next eight years he carried out a minute investigation of this substance and its properties. While determining its atomic weight, he thought it desirable, for the sake of accuracy, to weigh it in a vacuum, and even in these circumstances he found that the balance behaved in an anomalous manner, the metal appearing to be heavier when cold than when hot. This phenomenon he explained as a "repulsion from radiation," and he expressed his discovery in the statement that in a vessel exhausted of air a body tends to move away from another body hotter than itself. Utilizing this principle he constructed the radiometer (see *Ency. Brit.* vol. xix. p. 249 and *Supp.* RADIOMETER), which he was at first disposed to regard as a machine that directly transformed light into motion, but which was afterwards perceived to depend on thermal action. Thence he was led to his famous researches on the discharge of electricity through highly rarefied gases and on radiant matter, and to the development of his theory of a "fourth state of matter." In 1883 he began an inquiry into the nature and constitution of the rare earths. By repeated chemical fractionations he was able to divide yttrium into distinct portions which gave different spectra when exposed in a high vacuum to the spark from an induction coil. This result he considered to be due, not to any removal of impurities, but to an actual splitting-up of the yttrium molecule into its constituents, and he ventured to draw the provisional conclusion that the so-called simple bodies are in reality compound molecules, at the same time suggesting that all the elements have been produced by a process of evolution from one primordial stuff or "protyle." A later result of this method of investigation was the discovery of a new member of the rare earths, monium or victorium, the spectrum of which is characterized by an isolated group of lines, only to be detected photographically, high up in the ultra-violet end; the existence of this body was announced in his presidential address to the British Association at Bristol in 1898. In the same address he called attention to the conditions of the world's food supply, urging that with the low yield at present realized per acre wheat cannot long retain its position among the food-stuffs by which mankind is nourished, and that since nitrogenous manures are essential for an increase in the yield, the hope of averting starvation depends on the ability of the chemist to find an artificial method for fixing the nitrogen of the air. In addition to many other researches besides those here mentioned, Sir William Crookes has edited various books on chemistry and chemical technology, and has also given up a certain amount of time to the investigation of psychic phenomena, endeavouring to effect some measure of correlation between them and ordinary physical laws. He was knighted in 1897, and has received the Royal and Davy medals of the Royal Society, besides having filled the offices of President of the Chemical Society and of the Institution of Electrical Engineers.

**Crookston,** capital of Polk county, Minnesota, U.S.A., on the Red Lake River in the edge of Red River valley, on the Great Northern and the Northern Pacific Railways lines. Population (1890), 3457; (1900), 5359.

**Croos River.** See NIGERIA.

**Croquet.**—The line of demarcation between the old game and "New Croquet," as it is called, is not very difficult to draw, for croquet has had an experience quite unexampled in the history of games. The pastime eulogized by Lord Beaconsfield and illustrated by John Leech spread very rapidly. In some half dozen years after the appearance of the game, a croquet ground in a country house was deemed as important an adjunct as a conservatory. And then, almost in a night, the game disappeared. More than one reason has been assigned for this. It was pushed forward too quickly by experts and made too difficult; and then the croquet grounds were found admirably adapted for lawn tennis which in its early development could be played by man, woman, and child. The dimensions of the croquet ground have been altered since the days when Mr Henry Jones wrote his article in the ninth edition of the *Encyclopædia Britannica* (vol. vi.). A ground for match play must measure 35 yards in length by 28 yards in width, and the boundary must be marked with a white line. A little flag must be placed in each corner, and a spot of white near the flag, this spot being 3 feet from each boundary. Six hoops are used in the game, and two pegs. The hoop must be made of half-inch iron, and must stand up 12 inches above the ground. The hoop now used at all tournaments is the "Davidson," which develops into an inverted cone some 4 or 5 inches long under the soil, the broadest part at the top being a little broader than the iron above the surface. These hoops are very rigid, and if they get loose a tap with the mallet makes them tight again. The hoop must measure 4 inches across, inner measurement, and be square at the top. The pegs are of wood. They must be $1\frac{1}{2}$ inch in diameter and stand 2 feet out of the ground. One peg, the winning peg, is painted with four rings of colour, namely, blue, red, black, and yellow; the other peg is painted white. This distinction was made to indicate the top end and the bottom end of the ground, which was confusing sometimes at tournaments. Little cross bars should be on the top of the pegs to hold the clips. The balls are of boxwood, and weigh between $14\frac{1}{2}$ and $15\frac{1}{2}$ ozs. They are $3\frac{5}{8}$ inches in diameter. There must be a blue ball, a red ball, a black ball, and a yellow ball, and this sequence of the colours must be preserved. Thus if a player having the choice of balls and lead elects to play with yellow, blue must follow. Clips of the colour of the balls must be used. The clip indicates the next point in order of the player. The laws about mallets have changed since the old days of croquet when there was "no restriction as to the number, weight, size, shape, or material of the mallets." If you have indiarubber at one striking end you must not use it. Also your mallet must have the two striking ends perfectly vertical. The accompanying plan will show why a multiple of 5 and 4 has been selected for the dimensions of the ground. Up the central line the hoops are 7 yards apart, each peg 7 yards from the nearest outer hoop, 7 yards from each side hoop, 7 yards from the boundary. This is the setting, and the game consists in driving both balls through these hoops, in the order indicated by the numbers, up to the turning peg, and then returning to the winning peg, in a similar manner. At starting each player places his ball one foot away from hoop No. 1, placing it not slantingly, but in the exact centre. If he runs the hoop he plays again, and his turn can be prolonged by the following incidents:—1. Making a fresh point (hoop or peg) in order. 2. Hitting a ball that he has not hit since making a point. This hit is called a roquet, and after a roquet a player is compelled to *take croquet*. To take croquet you must place your ball in undeniable contact with the ball you have hit, and you may in your stroke glance away 20 yards (or other distance) after moving it half an inch, or you may roll it along with your own ball all that distance, or you may effect what is called a stop shot, and drive the croqueted ball a considerable distance while arresting the progress of your own ball almost completely. The *croquet* is an important stroke, and you must get from it all the advantage you can. But it is checked by certain minute regulations:—1. If the balls are not quite touching when you take croquet the adversary may have them put back and make you play the stroke over again. 2. If you fail to move both balls your turn ceases, and the adversary once more can have the balls put back. 3. If the croqueted ball reaches the boundary of the ground your turn ceases. 4. If your own ball reaches the boundary of the ground, unless intermediately it makes a roquet, your turn ceases. This, called the dead boundary law, was in existence when Mr Henry Jones wrote, but it has since been modified.



—·— indicates 7 yds.

The laws of croquet may here be briefly sketched. There are thirteen strokes called "foul." No point can be scored off any of them, the turn is lost, and the adversary, if he likes, can have the ball replaced after the stroke:—1. To strike the ball twice distinctly in playing it. 2. To push a ball without an audible knock. 3. To strike another ball besides one's own in playing, or taking aim. 4. To touch a rolling ball. 5. To allow a ball to rebound on the player's person or mallet. 6. To press a ball round a wire. 7. To play a ball after a roquet without taking croquet. 8. To fail to move the croqueted ball in the croquet stroke. 9. To take croquet from a ball without having first roqueted it. 10. To knock a hoop out of the ground with the mallet when making a stroke. 11. To use any part of the mallet, except the striking ends of the head, to propel a ball. 12. To use an indiarubber-tipped mallet. 13. To touch a ball improperly with hand, foot, or mallet. Besides these "foul strokes" there are six minor offences; it is a blemish in the laws that no defined penalties are attached to them, and players are advised to settle beforehand that the stroke must be played again if the adversary wishes it:—1. To play a stroke with a second mallet without having damaged the first. 2. To take croquet off a ball which you have sent not off but nearer than 3 feet to the boundary, without bringing it in three full feet before you play. 3. To lay down a mark to help your aim. 4. To play the first stroke at less than a foot from the first hoop, and not from a central spot. 5. To play with the wrong ball at starting. 6. To move a ball at rest accidentally. There are a few other laws. Only a rover can peg out a rover. A hoop is considered run when it cannot be touched with a straight edge from the playing side. On the other hand, a ball driven partly through a hoop from the non-playing side cannot run the hoop next stroke if it can be touched by a straight edge from the non-playing side. If the player play with a wrong ball, blue and black must be placed in one corner and red and yellow in the other corner, behind hoops 1 and 10, and the adversary may go on with either ball of his side.

A considerable advance has been made in the use of the mallet since 1877. Players are now divided into two groups, those who use *side-play* and those who use *front-play*. The distinction can be best understood if we imagine a player shooting at an object due north. The side player will face due east and strike with his mallet across the

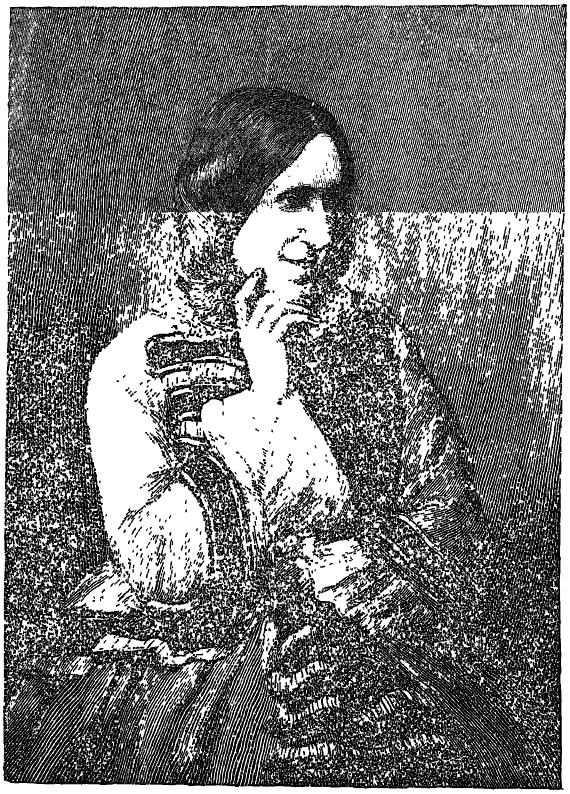
body, the front-player will face due north and look along the head of his mallet in taking aim. When Mr Henry Jones wrote his article side-play was the only play. Indeed a law in the code called "The Field" Laws absolutely forbids the use of front-play at all. The side-player usually stoops down and slopes his mallet, and delivers a stroke rather like a hockey stroke; he drives the ball, often very accurately, by a pure and unadulterated blow. But this stroke is uncertain. It depends entirely on eye and hand, and one bad stroke in a game may lose a match. The advantages of front-play are twofold. It allows the player to "look along the barrel," to use a phrase which fairly conveys the right idea. This is a great advantage, especially in strokes that require much accuracy, as with a hoop played at from a slanting direction. The second advantage of front-play is that the pendulum stroke can be used The player must have his mallet perfectly upright, his eye, his two hands, the line along the mallet head, the line through the centre of his ball, and the line through the centre of the ball aimed at must all be in the same vertical plane. His left hand will act as a pivot, the centre of the curve described by the mallet head in the stroke. The right hand will guide this mallet head, and it is essential to accuracy that it should be drawn up rather than back to preserve as much as possible the pendulum's curve. Much depends on the left hand, which clutches the mallet handle and acts as a pivot. The great difficulty of all is keeping this pivot during the stroke rigidly in the same vertical plane as the moving head.

The tactics of croquet have undergone a change since the days of Mr Henry Jones. The hoops for match play then were very difficult. They were of $\frac{1}{2}$-inch steel, and $3\frac{5}{8}$-inch span, and were fixed in a block of solid oak under the soil. This block was about the size and shape of a volume of the *Encyclopædia Britannica*. The diameter of a ball was only $\frac{1}{8}$th of an inch less than the span of the hoop, and when the ball touched the steel upright it was at once arrested. From this resulted very timid and cautious play. A tricky stroke was invented to put on what billiard players call "follow" in running a hoop. A player was afraid to attempt such a feat if any but a friendly ball was near. There was a great deal of what is called *finesse*, which means shooting into a corner to prevent your ball from helping the antagonist. Games were excessively long. Moderate players, and experts, who were not able to practise with the socketed hoops, soon gave up the game altogether. New croquet, by reverting to the 4-inch hoop and encouraging large handicaps, is giving to the scientific game a rapid and vast extension quite out of all precedent in the past. Excellent players are springing up everywhere, and with them a stronger and bolder game. A brief statement will show all that this means. Croquet is a unique game. If it is to be compared to any other it may be said that from the point of view of accurate striking and nice judgment of strength it approaches billiards, and from the intellectual side it approaches whist. Four balls, blue, red, black, and yellow, roll along the ground, and each of these balls affects the others at every stage of the game as much as the units of the little armies of spades and diamonds in whist. Red, we will say, hits blue. From that moment red dominates not only his own balls but those of his adversary, often for a considerable time. This is at once the weakness of croquet, and also its exceptional fascination. This command of the balls is called the *attack*, and the crucial strategy of the game is centred on two problems, namely, how to win when you have the attack, and how to get it when it is in the hands of the adversary. The object of the game being to pass both balls through the prescribed circuit of hoops, the player who possesses the attack will try to do this as fast as he can, passing not one hoop alone, but several, if practicable, in a turn. This sequence of hoops is called a *break*, and if it is effected with the aid of all the balls it is called a four-ball break, but if only three are available it is a three-ball break. The four-ball break is naturally the easiest. The principle of all breaks is to arrange to have a ball at your hoop the next in order as you come up to it, and another ball always at your next hoop but one in order. Thus if you are going up to hoop 5 (see plan) you should have a ball there to help you, and another at hoop 6. Let us say that with the aid of the first you run hoop 5; at once you send the ball that has assisted you on the turning peg itself, and you stop your ball in the croquet stroke close to the ball at hoop 6. The difficult feature of the setting is the four corner hoops, but these are run by the aid of what is called a centre ball, *i.e.*, you leave one of the balls in the centre of the ground as you run up to the stick. As you do so, you split the ball that has helped you to run hoop 6 away to hoop 8 and make the peg with the ball sent there to help you. Now comes in the work of the centre ball. You drive the ball that has helped you at the stick to the distant corner, hoop 9, and stop by the centre ball. You then hit it and take off to the ball left at hoop 8. In this way the centre ball will help you to do the four corner hoops 8, 9, 10, 11. Plainly the main object of the adversary must be to keep this fourth ball from you. His chief chance is coming in with a long shot, but he must send this as much as possible out of your game. (A. LI.)

**Cross, Mary Ann** (or, as she usually signed herself, Marian) (1819–1880), the famous English writer who is more generally known as **George Eliot,** was born at Arbury Farm, in Warwickshire, on 22nd November 1819. Her father, Robert Evans, was the agent of Mr Francis Newdigate, and the first twenty-one years of the great novelist's life were spent on the Arbury estate. She received an ordinary education at respectable schools till the age of seventeen, when her mother's death, and the marriage of her elder sister, called her home in the character of housekeeper. This, though it must have sharpened her sense, already too acute, of responsibility, was an immense advantage to her mind, and, later, to her career, for, delivered from the tiresome routine of lessons and class-work, she was able to work without pedantic interruptions at German, Italian, and music, and to follow her unusually good taste in reading. The life, inasmuch as she was a girl still in her teens, was no doubt monotonous, even unhappy. Just as Cardinal Newman felt, with such different results, the sadness and chain of evangelical influences from his boyhood till the end of his days, so Marian Evans was subdued all through her youth by a severe religious training which, while it pinched her mind and crushed her spirit, attracted her idealism by the very hardness of its perfect counsels. It is not surprising to find, therefore, that when Mr Evans moved to Coventry in 1841, and so enlarged the circle of their acquaintance, she became much interested in some new friends, Mr and Mrs Charles Bray and Mr Charles Hennell. Mr Bray had literary taste and wrote works on the *Education of the Feelings*, the *Philosophy of Necessity*, and the like. Mr Hennell had published *An Enquiry concerning the Origin of Christianity*. Miss Evans, then twenty-two, absorbed immediately these unexpected, and, at that time, daring habits of thought. So compelling was the atmosphere that it led to a complete change in her opinions. Kind in her affection, she was relentless in argument. She refused to go to church (for some time, at least), wrote painful letters to a former governess,—the pious Miss Lewis,—and barely avoided an irremediable quarrel with her father, a churchman of the old school. Here was rebellion indeed. But rebels come, for the most part, from the provinces where petty tyranny, exercised by small souls, show the scheme of the universe on the meanest possible scale. George Eliot was never orthodox again: she abandoned, with fierce determination, every creed, and although she passed, later, through various phases, she remained incessantly a rationalist in matters of faith and in all other matters. It is nevertheless true that she wrote admirably about religion and religious persons. She had learnt the evangelical point of view: she knew—none better—the strength of religious motives: vulgar doubts of this fact were as distasteful to her as they were to another eminent writer, to whom she refers in one of her letters (dated 1853) as "a Mr Huxley, who was the centre of interest" at some "agreeable evening." Her books abound in tributes to Christian virtue, and one of her own favourite characters was Dinah, the Quakeress, in *Adam Bede*.

She undertook, about the beginning of 1844, the translation of Strauss's *Leben Jesu*. This work, published in

1846, was considered scholarly, but it met, in the nature of things, with no popular success. On the death of Mr Evans in 1849, she went abroad for some time, and we hear of no more literary ventures till 1851, when she accepted the assistant-editorship of the *Westminster Review.* For a while she had lodgings at the offices of that publication in the Strand, London. She wrote several notable papers, and became acquainted with many distinguished authors of that period—among them Herbert Spencer, Carlyle, Harriet Martineau, Francis Newman, and George Henry Lewes. Her friendship with the last named led to a closer relationship, which she regarded as a marriage. Among the many criticisms passed upon this step (in view of the fact, among other considerations, that Lewes had a wife living at the time), no one has denied her courage in defying the law, or questioned the quality of her tact in a singularly false position. That she felt the deepest affection for Mr Lewes is evident; that we owe the development of her genius to his influence and constant sympathy is all but certain. Yet it is also sure that what she gained from his intimate companionship was heavily paid for in the unceasing consciousness that most people thought her guilty of a grave mistake, and found her written words, with their endorsement of traditional morality, wholly at variance with the circumstances of her private life. Doubts of her suffering in this respect will be at once dismissed after a study of her journal and letters. Stilted and unnatural as these are to a tragic degree, one can read well enough between the lines, and also in the elaborate dedication of each manuscript to "my husband" (in terms of the strongest love), that self-represssion, coupled with audacity, does not make for peace. Her sensitiveness to criticism was extreme: a flippant paragraph or an illiterate review with regard to her work actually affected her for days. The whole history of her union with Lewes is a complete illustration of the force of sheer will—in that case partly her own and not inconsiderably his—over a nature essentially unfitted for a bold stand against attacks. At first she and the man whom she had described "as a sort of miniature Mirabeau in appearance," went abroad, but they returned to England the same year and settled, after several moves, in lodgings at East Sheen.



GEORGE ELIOT.
*(From a Photo by the London Stereoscopic Co.)*

In 1854 she published *The Essence of Christianity*, a translation from Feuerbach, a philosopher to whom she had been introduced by Mr Bray. During 1855 she translated Spinoza's *Ethics*, wrote articles for the *Leader*, the *Westminster Review*, and the *Saturday Review*—then a new thing. It was not until the following year that she attempted the writing of fiction, and produced *The Sad Fortunes of the Reverend Amos Barton*—the first of the *Scenes of Clerical Life.* These, published in *Blackwood's Magazine*, were issued in two volumes in 1858. The Press in general extended a languid welcome to this work, and although the author received much encouragement from private sources, the few real critics were mostly noncommittal, and it was not until the publication of *Adam Bede* in 1859 that enthusiasm was attracted to the quality of the earlier production. *Adam Bede*, in many judgments George Eliot's masterpiece, met with a success (to use her own words) "triumphantly beyond anything she had dreamed of." In 1860 appeared *The Mill on the Floss.* After the sensational good fortune of *Adam Bede*, the criticism applied to the new novel seems to have been disappointing. We find Miss Evans telling her publisher that "she does not wish to see any newspaper articles." But the book made its way, and prepared an ever-growing army of readers for *Silas Marner* (1861), *Romola* (1862–63), and *Felix Holt* (1866). *The Spanish Gypsy* (1868), a drama in blank verse, received more public response than most compositions of the kind executed by those connected with the drama or with poetry only; and she published in 1874 another volume of verses, *The Legend of Jubal and other Poems.*

Any depression which the author may have felt with regard to the faults found with some of the last named books was completely cured by the praise bestowed on *Middlemarch* (1873). This profound study of certain types of English character was supreme at the time of its writing, and it remains supreme, of its school, in European literature. Thackeray is brilliant; Tolstoi is vivid to a point where life, not art, seems the question at issue; Balzac created a whole world; George Eliot did not create, but her exposition of the upper and middle class minds of her day is a masterpiece of scientific psychology. *Daniel Deronda* (1876), a production on the same lines, was less satisfactory. It exhibited the same human insight, the passionate earnestness, the insinuated special pleading for hard cases, the same intellectual strength, but the subject was unwieldy, almost forbidding, and, as a result, the novel, in spite of its distinction, has never been thoroughly liked. The death of Mr Lewes in 1878 was also the deathblow to her artistic vitality. She corrected the proofs of *Theophrastus Such* (a collection of essays), but she wrote no more. About two years later, however, she married Mr J. W. Cross, a gentleman whose friendship was especially congenial to a temperament so abnormally dependent on affectionate understanding as George Eliot's. But she never really recovered from her shock at the loss of George Lewes, and died at 4 Cheyne Walk, Chelsea, on the 22nd of December 1880.

No right estimate of her, whether as a woman, an artist, or a philosopher, can be formed without a steady recollection of her infinite capacity for mental suffering, and her need of human support. The statement that there is no sex in genius is, on the face of it, absurd. George Sand, certainly the most independent and dazzling of all women authors, neither felt, nor wrote, nor thought as a man. Saint Teresa, another great writer on a totally different

plane, was pre-eminently feminine in every word and idea. George Eliot, less reckless, less romantic than the Frenchwoman, less spiritual than the Spanish saint, was more masculine in style than either, but her outlook was not, for a moment, the man's outlook; her sincerity, with its odd reserves, was not quite the same as a man's sincerity, nor was her humour that genial, broad, unequivocal humour which is peculiarly virile. Hers approximated, curiously enough, to the satire of Jane Austen, both for its irony and its application to little everyday affairs. Men's humour, under all its headings, is on the heroic rather than the average scale. It is for the uncommon situations, not the daily tea-table. Again, George Eliot was a little scornful to those of both sexes who had neither special missions nor the consciousness of this deprivation. Men are seldom in favour of missions in any field. She demanded, too strenuously from the very beginning, an aim, more or less altruistic, from every individual, and as she advanced in life this claim became the more imperative, till at last it overpowered her art, and transformed a great delineator of humanity into an eloquent observer with far too many personal prejudices. But she was altogether free from cynicism, bitterness, or the least tendency to pride of intellect. She suffered from bodily weakness the greater part of her life, and but for an extraordinary mental health—inherited from the fine yeoman stock from which she sprang—it is impossible that she could have retained, at all times, so sane a view of human conduct, or been the least sentimental among women writers of the first rank—the one wholly without morbidity in any disguise. The accumulation of mere book knowledge, as opposed to the friction of a life spent among all sorts and conditions of men, drove George Eliot at last to write as a specialist for specialists: joy was lost in the consuming desire for strict accuracy: her genius became more and more speculative, less and less emotional. The highly trained brain suppressed the impulsive heart,—the heart described with such candour and pathos as Maggie Tulliver's in *The Mill on the Floss.* For this reason—chiefly because philosophy is popularly associated with inactive depression, whereas human nature is held to be eternally exhilarating — her later works have not received so much praise as her earlier productions. But one has only to compare *Romola* or *Daniel Deronda* with the compositions of any author except herself to realize the greatness of her designs, and the astonishing gifts brought to their final accomplishment.

*Life of George Eliot.* Edited by J. W. CROSS. 3 vols. 1885–87. (P. M. T. C.)

**Crossen,** a town of Prussia, at the influx of the Bober into the Oder, 31 miles south-east of Frankfurt by rail, capital of the circle of Crossen, Government district of Frankfurt. It has two Protestant and one Catholic church, a *real*, a mechanics', a horticultural, and other schools, and a brisk shipping trade. Population (1890), 6657; (1895), 7911; (1900), 7369.

**Crowe, Sir Joseph Archer** (1828–1896), English consular official and art critic, was born in London on 25th October 1828. At an early age he showed considerable aptitude for painting, and entered the studio of Paul Delaroche in Paris, where his father then resided as correspondent of the *Morning Chronicle*, but he never achieved any great distinction with the brush. During the Crimean War he was the correspondent of the *Illustrated London News*, and during the Austro-Italian War represented the *Times* in Vienna. He was British consul-general in Leipzig from 1860 to 1872, and in Düsseldorf from 1872 to 1880, when he was appointed commercial attaché in Berlin, being transferred in a like capacity to Paris in 1882. In 1883 he was secretary to the Danube Conference in London; in 1889 plenipotentiary at the Samoa Conference in Berlin; and in 1890 British envoy at the Telegraph Congress in Paris, in which year he was made K.C.M.G. During a sojourn in Italy, 1846–1847, he cemented a lifelong friendship with the Italian painter Cavalcaselle, and the two friends engaged in works of artistic research. Notable among these are *Early Flemish Painters* (London, 1857); *A New History of Painting in Italy from the Second to the Sixteenth Century* (London, 1864–66, 3 vols.). The latest work from his own pen was *Reminiscences of Thirty-Five Years of My Life.* He died at Schloss Gamburg in Bavaria on 6th September 1896.

**Crowther, Samuel Adjai** (18? –1891), African missionary-bishop, was born in Yoruba, and was sold into slavery in 1821. Next year he was rescued, with many other captives, by H.M. ship *Myrmidon*, and was landed at Sierra Leone. Educated there in one of the Church Missionary Society's schools, he was baptized on 11th December 1825. In the course of time he became a teacher at Fousah Bay, and afterwards an energetic missionary on the Niger. Summoned to England in 1842, he entered the Church Missionary College at Islington. On 11th June in the following year he was ordained by Bishop Blomfield. Returning to his native land, he laboured with great success amongst his own people, and afterwards at Abeokuta. Here he devoted himself to the preparation of school-books, and the translation of the Bible and Prayer-Book into Yoruba and other dialects. He also established a trade in cotton, and improved the native agriculture. In 1857 he commenced the third expedition up the Niger, and after labouring with varied success, and encountering great danger from a powerful native chieftain, returned to England and was consecrated, on St Peter's Day 1864, first Bishop of the Niger Territories, and was warmly welcomed in his native land. Before long a commencement was made of the missions to the Delta of the Niger, and between 1866 and 1884 congregations of Christians were formed at Bonny, Brass, and New Calabar, but the progress made was slow and subject to many impediments. In 1872, during a violent persecution, two converts suffered martyrdom. In 1888 the tide turned, and several chiefs embraced Christianity, and on Bishop Crowther's return from another visit to England, the large iron church known as "St Stephen's Cathedral" was opened, and all the objects of superstitious worship were given up. For three years more the bishop laboured, and then died of paralysis at the end of October 1891, having displayed as a missionary for many years untiring industry, great practical wisdom, and deep piety. (G. F. M*.)

**Croydon,** a parish and county borough, 10 miles south of London by rail, in the north-east of Surrey. It was once supposed to mark the site of the Roman station *Noviomagus*, but this opinion is now rejected, and Holwood Hill, Keston, is believed to be the true site of that station. It was formed into a municipal borough in 1883, a parliamentary borough in 1885, and a county borough in 1888. The population of the registration district was in 1881, 101,241; in 1891, 151,771; and in 1901, 194,425. The population of the county borough in 1891 was 102,695, and in 1901, 133,885. The parish church of St John the Baptist appears to have been built in the 14th and 15th centuries, but to have contained remains of an older building. The church was restored or rebuilt in the 16th century, and again restored by Sir Gilbert G. Scott in 1857–59. It was destroyed by fire, with the exception of the tower, on 5th January 1867, and

was at once rebuilt by Scott on the old lines. Addington Park, 3½ miles from Croydon, was purchased for the residence, in 1807, of the archbishop of Canterbury, but was sold in consequence of Archbishop Temple's decision to reside at the Palace, Canterbury. Whitgift's Hospital (1596) was restored in 1860, and the Whitgift Grammar School was built in 1871. Few towns have developed the modern spirit so thoroughly as Croydon has. It makes full use of electric lighting, and has one of the lowest death-rates in the United Kingdom.

**Crozet Islands,** an uninhabited insular group in the Indian Ocean, 46°–47° S. and 50° E. They are mountainous, with summits from 4000 to 5000 feet high, and are disposed in two divisions—Penguin or Inaccessible, Hog, Possession, East; and the Twelve Apostles. Like Kerguelen, Heard, Prince Edward, Marion, and the other clusters in these southern waters, they appear to be of igneous formation; but owing to the bleak climate and their inaccessible character they are seldom visited, and have never been explored since their discovery by Marion in 1771. Possession, the highest, has a snowy peak said to exceed 5000 feet. Hog takes its name from the animals which were here let loose by an English captain many years ago, but have since disappeared. Rabbits burrow in the heaps of scoria on the slopes of the mountains.

**Cruikshank, George** (1792–1878), English artist, caricaturist, and illustrator, was born in London on the 27th September 1792. By natural disposition and collateral circumstances he may be accepted as the type of the born humoristic artist predestined for this special form of art. His grandfather had taken up the arts, and his father, Isaac Cruikshank, followed the painter's profession. Amidst these surroundings the children were born and brought up, their first playthings the materials of the arts their father practised. George followed the family traditions with amazing facility, easily surpassing his compeers as an etcher. When the father died, about 1811, George, still in his "teens," was already a successful and popular artist. All his acquisitions were native gifts, and of home-growth; outside training, or the serious apprenticeship to art, were dispensed with, under the necessity of working for immediate profit. This lack of academic training the artist at times found cause to regret, and at some intervals he made exertions to cultivate the knowledge obtainable by studying from the antique and drawing from life at the schools. From boyhood he was accustomed to turn his artistic talents to ready account, disposing of designs and etchings to the printsellers, and helping his father in forwarding his plates. Before he was twenty his spirited style and talent had secured popular recognition; the contemporary of Gillray, Rowlandson, Alken, Heath, Dighton, and the established caricaturists of that generation, he developed great proficiency as an etcher. Gillray's matured and trained skill had some influence upon his executive powers, and when the older caricaturist passed away in 1815, George Cruikshank had already taken his place as a satirist. Prolific and dexterous beyond his competitors, for a generation he delineated Tories, Whigs, and Radicals with fine impartiality. Satirical capital came to him from every public event,—wars abroad, the enemies of England (for he was always fervidly patriotic), the camp, the Court, the Senate, the Church; low life, high life; the humours of the people, the follies of the great. In this wonderful gallery the student may grasp the popular side of most questions which for the time being engaged public attention.

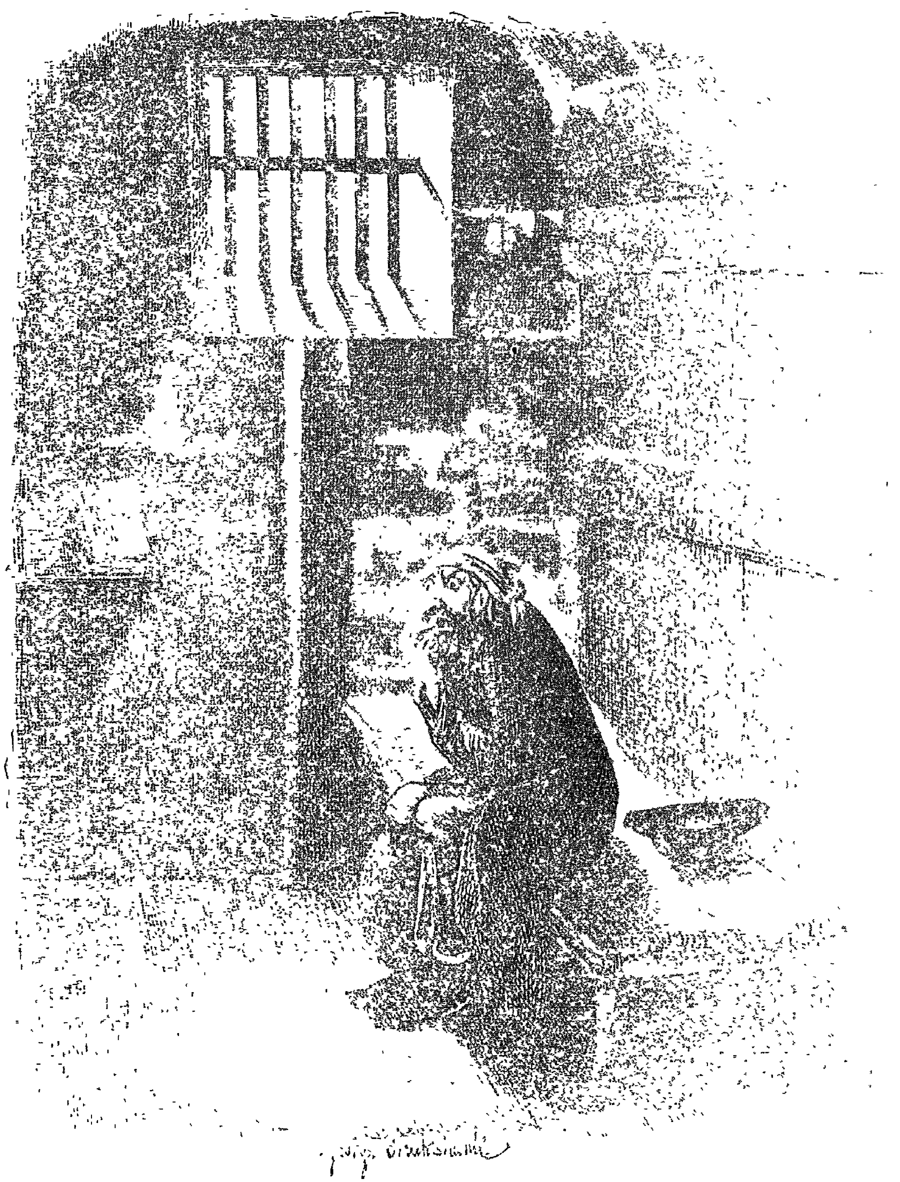
A vast number of Cruikshank's spirited cartoons were published as separate caricatures, all coloured by hand; others formed series, or were contributed to satirical magazines, the *Satirist, Town Talk, The Scourge* (1811–16), and the like ephemeral publications. In conjunction with William Hone's scathing tracts, G. Cruikshank produced political satires to illustrate the series of facetiæ and miscellanies, like *The Political House that Jack Built* (1819).

Of a more genially humoristic order are his well-known book illustrations, now so deservedly esteemed for their inimitable fun and frolic, among other qualities, such as the weird and terrible, in which he excelled. Early in this series came *The Humorist* (1819–21) and *Life in Paris* (1822). The well-known series of *Life in London*, conjointly produced by the brothers I. R. and G. Cruikshank, has enjoyed a prolonged reputation, and is still sought after by collectors. Grimm's *Collection of German Popular Stories* (1824–26), in two series, with 22 inimitable etchings, are in themselves sufficient to account for G. Cruikshank's reputation. To the first fourteen volumes (1837–43) of *Bentley's Miscellany*, Cruikshank contributed 126 of his best plates, etched on steel, including the famous illustrations to *Oliver Twist, Jack Sheppard, Guy Fawkes*, and *The Ingoldsby Legends*. For W. Harrison Ainsworth, Cruikshank illustrated *Rookwood* (1836), and *The Tower of London* (1840); the first six volumes of *Ainsworth's Magazine* (1842–44) were illustrated by him with several of his finest suites of etchings. For C. Lever's *Arthur O'Leary* he supplied 10 full-page etchings (1844), and 20 spirited graphic etchings for Maxwell's lurid *History of the Irish Rebellion in 1798* (1845). Of his own speculations, mention must be made of *George Cruikshank's Omnibus* (1841) and *George Cruikshank's Table Book* (1845), as well as his *Comic Almanack* (1835–1853). *The Life of Sir John Falstaff* contained 20 full-page etchings (1857–58). These are a few leading items amongst the thousands of illustrations emanating from that fertile imagination. As an enthusiastic teetotal advocate, G. Cruikshank produced a long series of pictures and illustrations, pictorial pamphlets, and tracts; the best known of these are *The Bottle*, 8 plates (1847), with its sequel, *The Drunkard's Children*, 8 plates (1848), with the ambitious work, *The Worship of Bacchus*, published by subscription after the artist's oil painting, now in the National Gallery, London, to which it was presented by his numerous admirers.

Regarding manual dexterity, George Cruikshank's technical and manipulative skill as an etcher was such that Ruskin and the best judges have placed his productions in the foremost rank; in this respect his works have been compared favourably with the masterpieces of etching. George Cruikshank died at 263 Hampstead Road on 1st February 1878, aged 86 years. His remains rest in St Paul's Cathedral. (J. GO*.)

**Crustacea.** Carcinology, as the science of crustacea is now called, begins with Aristotle, and, making no substantial advance in the days of Pliny, Aelian, Oppian, recommences in the 16th century with the writings of Rondelet, Belon, and Gesner. After several authors of various calibre, such as Friderich Martens, Ray, Swammerdam, Fritsch, had made more or less useful contributions to it, the science in the middle of the 18th century entered upon its modern phase under the auspices of Linnæus, though without much assistance from that great naturalist in person. His voluminous contemporaries Seba and Gronovius were still somewhat mediæval, while Pallas of the same date in time was a modern in spirit. But carcinology at large first took shape and definiteness in the last quarter of the 18th century through the writings of J. C. Fabricius, beginning with his *Systema Entomologiæ* in 1775. Important aid was rendered also by the works of O. F. Müller and J. F. Herbst. During the first quarter of the next century a great advance was made by the numerous writings of Latreille and Leach. From 1828 to 1855 the dominant writers were Henri Milne-Edwards, Henrik Krøyer, and J. D. Dana, the first producing his still valuable *Histoire naturelle des Crustacés*, the second his long series of important papers in the Danish *Naturhistorisk Tidsskrift*, and the third, after many preliminary essays, his vast report on the crustacea of the U.S. Exploring Expedition under Wilkes. During the same period other notable expeditions collected crustacea, and other eminent observers wrote about them, among well-known names being those of Guérin-Méneville, Vaughan Thompson, Lucas, Zaddach, Rathke, the two Costas, Harry Goodsir, Adam White, and Dr Baird. During the next ten or twelve years, with the older authors for the most part still writing, we find prominent the additional names of

"Oliver Twist asking for more."



"Fagin in his Cell."

ILLUSTRATIONS FOR *OLIVER TWIST.* By GEORGE CRUIKSHANK.

Leydig, Lilljeborg, Stimpson, Westwood, Bate, Kinahan, Thorell, and the incipient merit of Alphonse Milne-Edwards, C. Claus, and G. O. Sars. Thenceforward down to the present day the bibliography of crustacea exhibits a host of writers and a flood of records. From every zone, from water fresh, brackish, or saline, exposed or subterranean, from the surface of sea or lake down to almost every accessible depth, and from the surface of the land up to almost every accessible height, crustacea have been obtained, captured by new devices, examined by new methods, studied with a new zeal, and revealing new forms and relations in a previously unsuspected and still unceasing and increasing variety. From the axils of a plant to the nostrils of a fish or the intestines of an annelid, crustaceans can accommodate themselves to every kind of strange habitation, and the descriptions of them are often equally fugacious, since they may have to be tracked through an indefinite number of serials in nine or ten different languages. For an effective grasp of knowledge already acquired, and the adjustment of future acquisitions, it is clear that the mind of the naturalist is always yearning for classification;—in the crustacea the basis for this has been sought in many directions,—in the general shape, the eyes, the locomotive appendages, the mouth-organs, the breathing apparatus, the structure of the stomach, the genital organs, the circulatory and nervous systems, the development of the young, and the phylogeny. Unfortunately the last, which would be most decisive for a natural system, is likely always to remain the most speculative. On the other hand, parts of the organism which might seem least adapted for systematic purposes may be of service, since a high authority has stated that in the Copepoda the number and distribution of the hairs on the swimming-feet are capable of affording valuable characters for genera, or even for subfamilies.

As might be expected, in the great expansion of the class, with so much attention concentrated on its arrangement, numerous classificatory changes have been proposed, and many of them have been established on apparently satisfactory grounds, during recent years. But these alterations leave us at liberty to maintain the three leading divisions, the Malacostraca, Entomostraca, and Thyrostraca, while keeping apart the small group of the Leptostraca, established by Claus for the Nebaliidæ, as a connecting link between the first division and the second. Briefly, all the four may be distinguished as follows:

Malacostraca are those crustacea in which, apart from an ocular segment and telson, the assignable segments are nineteen in number. The first antennæ often have more than one branch.

Leptostraca have more than nineteen segments, and a second branch on their first antennæ.

In the rest of the crustacea the assignable segments are more or fewer than nineteen, and the first antennæ never have more than one branch. These form two divisions:—

Entomostraca, in which the antennæ of normal adults are unconcealed; and

Thyrostraca, more commonly called Cirripedia, in which the antennæ of adults are concealed.

Another division, named Gigantostraca, including the extinct Merostomata and Trilobita, and the still existing Xiphosura, represented by *Limulus*, the so-called king-crab, is by some eminent authorities altogether banished from the class of crustacea. By others the affinity of trilobitas and king-crabs with *Apus* and other phyllopod entomostracans is strictly maintained.

In regard to the Leptostraca it is worthy of note that G. H. Parker, in the *Mittheilungen aus der zoologischen Station zu Neapel* for 1895, endorses the opinion of Claus on the optic ganglia of the Nebaliidæ, both authors holding that these belong rather to the Malacostracan than to the Entomostracan type. On the other hand, the trunk limbs in this family are strikingly phyllopodan in character.

The unity of the whole crustacean class often receives unexpected illustrations, thus it is a notable characteristic of the Malacostraca that the seven pairs of limbs of the middle body are seven-jointed, although through subdivision or coalescence this peculiarity may be obscured in some of these limbs. But that the number of seven joints should be normal also for the maxillipeds, which immediately precede the median appendages above mentioned, is interesting less as a distinctive character of the Malacostraca, than for the opposite reason, as connecting them with the Entomostraca, inasmuch as the same number of joints is found to recur in what are now understood to be the homologous maxillipeds of the Copepoda.

An exposition of the present state of science in regard to each of the divisions above distinguished will be given under its own name, except that the linking Leptostraca, will, for convenience, be grouped with their allies (nearer or more remote), the Entomostracan Phyllopoda.

(T. R. R. S.)

**Csaba (Békés),** a market-town of Central Hungary, nearly 50 miles south-west of Grosswardein. There are many industrial establishments (including 8 steam mills), a Lutheran gymnasium, and a theatre. Population (1891), 34,243; (1900), 37,547.

**Csengery, Anton** (1822–1880), Hungarian publicist, and a historical writer of great influence on his time, was born at Nagyvárad on the 2nd of June 1822. He took, at an early date, a very active part in the literary and political movements immediately preceding the Hungarian Revolution of 1848. He and Baron Sigismund Kemény may be considered as the two founders of high-class Magyar journalism. After 1867 the greatest of modern Hungarian statesmen, Francis Deák, attached Csengery to his personal service, and many of the momentous state documents inspired or suggested by Deák were drawn up by Csengery. In that manner his influence, as represented by the text of many a statute regulating the relations between Austria and Hungary, is one of an abiding character. As an historical writer he excelled chiefly in brilliant and thoughtful essays on the leading political personalities of his time, such as Paul Nagy, Bertalan, Szemere, and others. He also commenced a translation of Macaulay's *History*. He died at Budapest on the 13th of July 1880.

**Csiky, Gregor** (1842–1891), one of the foremost dramatists of modern Hungary, was born on the 8th of December 1842 at Pankota, in the county of Arad. He studied Roman Catholic theology at Pest and Vienna, and was Professor in the Priests' College at Temesvar from 1870–78. In the latter year, however, he joined the Evangelical Church, and took up literature. Beginning with novels and works on ecclesiastical history, which met with some recognition, he ultimately devoted himself to writing for the stage. Here his career was one of almost instantaneous success. Already in his *Az ellenállhatatlan* ("L'Irresistible"), which obtained a prize from the Hungarian Academy, he showed the distinctive features of his talent—directness, freshness, realistic vigour, and highly individual style. In rapid succession he enriched Magyar literature with realistic *genre*-pictures, such as *A Proletárok* ("Proletariate"), *Buborékok* ("Bubbles"), *Két szerelem* ("Two Loves"), *A szégyenlős* ("The Bashful"),

*Athalia*, &c., in all of which he seized on one or another feature or type of modern life, dramatizing it with unusual intensity, qualified at the same time by chaste and well-balanced diction. Of the latter, his classical studies may, no doubt, be taken as the inspiration, and his translation of Sophocles and Plautus will long rank with the most successful of Magyar translations of the ancient classics. Among the best known of his novels are *Arnold*, *Az Atlasz család* ("The Atlas Family"). He died at Budapest on the 19th November 1891.

**Csongrád,** a large market-town of Hungary, at the confluence of the Tisza and Körös. It has a population (1900) of 22,619,—all Hungarians,—chiefly engaged in agriculture, for which the fine soil of the district (57,623 acres) is specially adapted.

**Csorba, Lake of,** a tourist centre in the county of Liptò, North Hungary, situated in the Tátra Mts., 4432 feet above sea-level. The lake, which is called the "Pearl of the Tátra," is of inconsiderable size, but its picturesque position at the foot of the highest snow-covered peaks, bordered by dense pine-forests, has given it a great vogue, and since 1895 it has been connected by a mountain railway with the chief line from Kassa to Oderberg.

**Ctenophora** were briefly described by Professor Huxley in 1875 (see ACTINOZOA, *Ency. Brit.* vol. i.) as united with what we now term Anthozoa to form the group Actinozoa; but little was known of the intimate structure of those remarkable and beautiful forms till the appearance in 1880 of Chun's Monograph of the Ctenophora occurring in the Bay of Naples. They may be defined as Cœlentera which exhibit both a radial and bilateral symmetry of organs; with a stomodæum; with a mesenchyma which is partly gelatinous but partly cellular; with eight meridianal rows of vibratile paddles formed of long fused or matted cilia; lacking nematocysts (except in one genus). An example common on the British coasts is furnished by Hormiphora. In outward form this is an egg-shaped ball of clear jelly, having a mouth at the pointed (oral) pole, and a sense-organ at the broader (aboral) pole. It possesses eight meridians (costæ) of iridescent paddles in constant vibration, which run from near one pole towards the other: it has also two pendent feathery tentacles of considerable length, which can be retracted into pouches. The mouth leads into an ectodermal stomodæum ("stomach"), and the latter into an endodermal funnel (infundibulum); these two are compressed in planes at right angles to one another, the sectional long axis of the stomodæum lying in the so-called sagittal (stomodæal or gastric) plane, that of the funnel in the transverse (tentacular or funnel) plane. From the funnel, canals are given off in three directions: (*a*) a pair of paragastric (stomachal, or stomodæal) canals run orally, parallel to the stomodæum, and end blindly near the mouth; (*b*) a pair of perradial canals run in the transverse plane towards the equator of the animal; each of these becomes divided into two short canals at the base of the tentacle sheath which they supply, but has previously given off a pair of short interradial canals, which again bifurcate into two adradial canals; all these branches lie in the equatorial plane of the animal, but the eight adradial canals then open into eight meridianal canals which run orally and aborally under the costæ; (*c*) a pair of aboral vessels which run towards the sense-organ, each of which bifurcates; of the four vessels thus formed, two only open at the sides of the sense-organ, forming the so-called excretory apertures. These three sets of structures, with the funnel from which they rise, make up the endodermal cœlenteron, or gastro-vascular system. The generative organs are endodermal by origin, borne at the sides of the meridianal canals as indicated by the signs ♂ ♀. There exists a subepithelial plexus with nerve cells and fibres, similar to that of jelly-fishes. The sense-organ of the aboral pole is complex, and lies under a dome of fused cilia shaped like an inverted bell-jar; it consists of an otolith, formed of numerous calcareous spheroids, which is supported on four plates of fused cilia termed balancers, but is otherwise free. The ciliated ectoderm below the organ is markedly thickened, and perhaps functionally represents a nerve-ganglion: from it eight ciliated furrows radiate outwards, two passing under each balancer as through an archway, and diverge each to the head of a meridianal costa. These ciliated furrows stain deeply with osmic acid, and nervous impulses are certainly transmitted along them. Locomotion is effected by strokes of the paddles in an aboral direction, driving the animal mouth forwards through the water: each paddle or comb (hence Ctenophora) consists of a plate of fused or matted cilia set transversely to the costa. The myoepithelial cells (= neuro-muscular cells of *Ency. Brit.* vol. xii. p. 549), characteristic of other Cœlentera, are not to be found in this group. On the other hand there are well-marked muscle fibres in definite layers, derived from special mesoblastic cells in the embryo, which are embedded in a jelly; these in their origin and arrangement are quite comparable to the mesoderm of Triploblastica, and, although the muscle-cells of some jelly-fish exhibit a

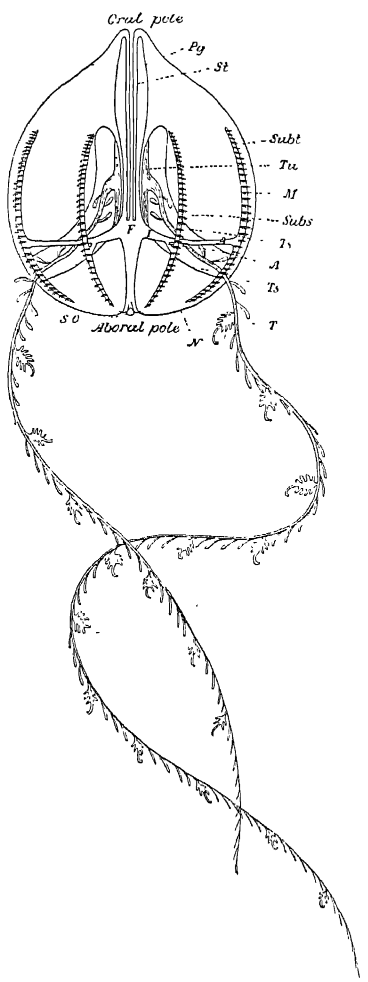


FIG. 1.—Schematic drawing of a cydippid from the side. (*After Chun.*) *A*, adradial canals; *F*, infundibulum; *I*, interradial canal: *M*, meridianal canal lying under a costa; *N*, ciliated furrow from sense pole to costa; *Pg*, paragastric canal; *SO*, sense-organ; *St*, stomodæum; *Subs*, sub-sagittal costa; [illegible]cular costa; *T*, tentacle; *Ts*, boundaries of tentacle-sheath.

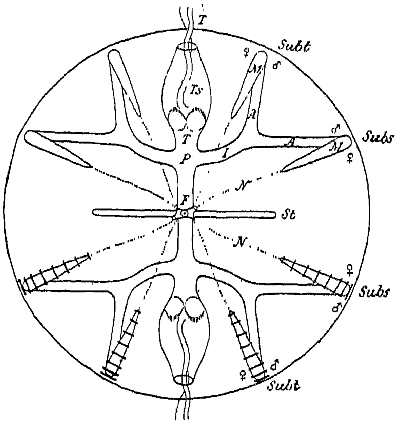

FIG. 2.—Schematic drawing of a cydippid from the aboral pole. (*After Chun.*) *T* (centrally), tentacular canal, and (distally) tentacle; ♂, position of testes; ♀, position of ovaries; other letters as in Fig. 1. The stomodæum lies in the sagittal plane, the funnel and tentacles in the transverse or tentacular plane.

somewhat similar condition, nothing so highly specialized as the mesenchyme of Ctenophora occurs in any other Cœlenterate. The nematocysts being nearly absent from their group, their chief function is carried out by adhesive lasso-cells.

The Ctenophora are classified as follows:—

| | | | |
|---|---|---|---|
| Subclass i. **Tentaculata**, | Order 1. Cydippidea, | *Hormiphora.* |
| | ,, 2. Lobata, | *Deiopea.* |
| | ,, 3. Cestoidea, | *Cestus.* |
| ,, ii. **Nuda**, | ,, | *Beroe.* |

The **Tentaculata**, as the name implies, may be recognized by the presence of tentacles of some sort. The Cydippidea are generally spherical or ovoid, with two long retrusible pinnate tentacles: the meridianal and paragastric canals end blindly. An example of these has already been briefly described. The Lobata are of the same general type as the first Order, except for the presence of four circumoral auricles (processes of the subtransverse costæ) and of a pair of sagittal outgrowths or lobes, on to which the subsagittal costæ are continued. Small accessory tentacles lie in grooves, but there is no tentacular pouch; the meridianal vessels anastomose in the lobes. In the Cestoidea the body is compressed in the transverse plane, elongated in the sagittal plane, so as to become riband-like: the subtransverse costæ are greatly reduced, the subsagittal

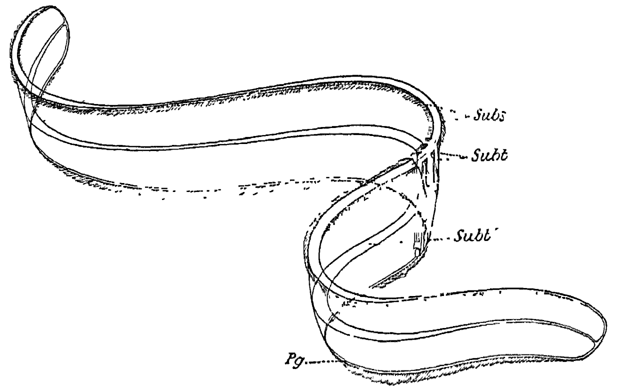

Fig. 3.—Schematic drawing of cestus. (*After Chun.*) *Subs*, subsagittal costæ; *Subt*, much reduced subtentacular costæ; *Subt*, branch of the subtentacular canal which runs along the centre of the riband; *Pg*, continuation of the paragastric canal at right angles to its original direction along the lower edge of the riband. At the right hand end the last two are seen to unite with the subsagittal canal.

costæ extend along the aboral edge of the riband. The subsagittal canals lie immediately below their costæ aborally, but continuations of the subtransverse canals round down the middle of the riband, and at its end unite, not only with the subsagittal, but also with the paragastric canals which run along the oral edge of the riband. The tentacular bases and pouches are present, but there is no main tentacle as in Cydippidea; fine accessory tentacles lie in four grooves along the oral edge. The subclass **Nuda** have no tentacles of any kind; they are conical or ovoid, with a capacious stomodæum like the cavity of a thimble. There is a cœlenteric network formed by anastomoses of the meridianal and paragastric canals all over the body.

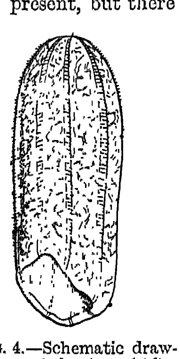

Fig. 4.—Schematic drawing of beröe. (*After Chun.*)

The embryology of Callianira has been worked out by Metschnikoff. Segmentation is complete and unequal, producing macromeres and micromeres marked by differences in the size and in yolk-contents. The micromeres give rise to the ectoderm; each of the sixteen macromeres, after budding off a small mesoblast cell, passes on as endoderm. A gastrula is established by a mixed process of embole and epibole. The mesoblast cells travel to the aboral pole of the embryo, and there form a cross-shaped mass, the arms of which lie in the sagittal and transverse planes (perradii).

There can be but little question of the propriety of including Ctenophora among the Cœlentera. The undivided cœlenteron (gastro-vascular system) which constitutes the sole cavity of the body, the largely radial symmetry, the presence of endodermal generative organs on the cœlenteric canals, the subepithelial nerve-plexus, the mesoglœa-like matrix of the body—all these features indicate affinity to other Cœlentera, but, as has been stated in the article under that title, the relation is by no means close. In the ninth edition of this work (see Hydrozoa) some stress was laid on Haeckel's discovery of Ctenaria as a possible link-form between Hydromedusæ and Ctenophora, but this view has now been generally abandoned. At what period the Ctenophora branched off from the line of descent, which culminated in the Hydromedusæ and Scyphozoa of to-day, is not clear, but it is practically certain that they did so before the point of divergence of these two groups from one another. The peculiar sense-organ, the specialization of the cilia into paddles with the corresponding modifications of the cœlenteron, the anatomy and position of the tentacles, and, above all, the character and mode of formation of the mesenchyme, separate them widely from other Cœlentera.

The last-named character, however, combined with the discovery of two remarkable organisms, Cœloplana and Ctenoplana, has suggested affinity to the flat-worms termed Turbellaria. Ctenoplana, the best known of these, has recently been redescribed by Willey (*Quart. Journ. Micr. Sci.* xxxix., 1896). It is flattened along the axis which unites sense-organ and mouth, so as to give it a dorsal (aboral) surface, and a ventral (oral) surface on which it frequently creeps. Its costæ are very short, and retrusible; its two tentacles are pinnate and are also retrusible. Two crescentic rows of ciliated papillæ lie in the transverse plane on each side of the sense-organ. The cœlenteron exhibits six lobes, two of which Willey identifies with the stomodæum of other Ctenophora; the other four give rise to a system of anastomosing canals such as are found in Beröe and Polyclad Turbellaria. An aboral vessel embraces the sense-organ, but has no external opening. Ctenoplana is obviously a Ctenophoran flattened, and of a creeping habit. Cœloplana is of similar form and habit, with two Ctenophoran tentacles: it has no costæ, but is uniformly ciliated. These two forms at least indicate a possible stepping-stone from Ctenophora to Turbellaria, that is to say, from Diploblastic to Triploblastic Metazoa. By themselves they would present no very weighty argument for this line of descent from two-layered to three-layered forms, but the coincidences which occur in the development of Ctenophora and Turbellaria,—the methods of segmentation and gastrulation, of the separation of the mesoblast cells, and of mesenchyme formation,—together with the marked similarity of the adult mesenchyme in the two groups, have led many to accept this pedigree. In his Monograph on the Polyclad Turbellaria of the Bay of Naples, Lang regards a Turbellarian, so to say, as a Ctenophora, in which the sensory pole has rotated forwards in the sagittal plane through 90° as regards the original oral-aboral axis, a rotation which actually occurs in the development of Thysanozoon (Müller's larva); and he sees, in the eight lappets of the preoral ciliated ring of such a larva, the rudiments of the costal plates. According to his view, a simple early Turbellarian larva, such as that of Stylochus, most nearly represents for us to-day that ancestor from which Ctenophora and Turbellaria are alike derived. For details of this brilliant theory, the reader is referred to the original monograph.

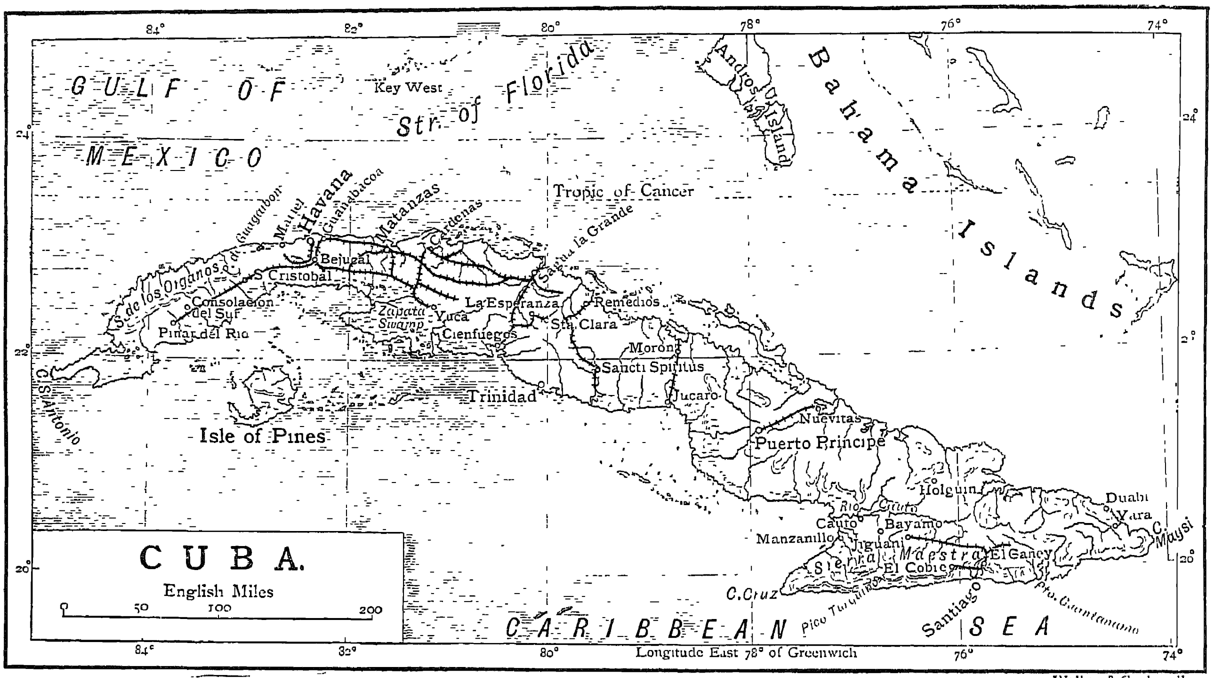
A list of the chief works relating to the group may be found at the end of Bourne's chapter on Ctenophora, in part ii. of Lankester's *Treatise on Zoology* (1900).

(G. H. Fo.)

# CUBA.

## I. Geography and Statistics.

CUBA is the largest and most populous of the West India islands. It lies directly south of Florida, the south-easternmost of the United States, being separated from it by the Strait of Florida, 100 miles in width. It is included between the meridians of 74° and 85° W. of Greenwich, and the parallels of 19° 40′ and 23° 33′ N. latitude. Its length from Cape Maisi on the east to Cape San Antonio on the west is 730 miles, while its breadth from north to south ranges from 25 miles in the neighbourhood of Havana to 100 miles in the eastern part of the island. Its area, including the Isle of Pines, which is under its jurisdiction, is 44,000 square miles. In its relief the island presents little appearance of unity of plan. West of Havana it is traversed, in a direction parallel to its length, by a mountain range, the Sierra de los Organos, whose summits rise to altitudes of 2000 to 2500 feet, culminating in Pan de Guagaibon, with the latter altitude. To the north and south of the crest of this range the land slopes to the coast, the southern slopes, known as Vuelta de Abajo, being the most celebrated tobacco lands of the island. The middle portion of the island consists mainly of low rolling plains, with shallow stream-valleys, rising in a few places into plateaux, which have been deeply dissected by erosion. The eastern portion of the island is mountainous, consisting in great part of a plateau, 2000 to 3000 feet high, deeply cut by streams, while closely bordering the southern coast from Santiago westward to Cape Cruz is Sierra Maestra, rising to an average altitude of 5000 feet, and culminating in Pico Turquino, said to be 8320 feet high. The rivers of Cuba are short, and except for the estuaries at their mouths, are not navigable. The only exception is the Rio Cauto, the largest river of the island, which drains a broad and fertile valley lying north of Sierra Maestra. This river has



Walker & Cockerell sc.

a length of 150 miles, one-third of which is navigable for light-draught vessels. Much of the south coast of the island is bordered by swamps, which in the longitude of Matanzas expand to a great breadth, 75 by 30 miles, forming the Zapata Swamp. Much of the north coast, especially along the middle part of the island, is fringed by low mangrove-covered islets, which are in the main uninhabited. The harbours are numerous and excellent. Most of them are pouch-shaped, with narrow, often sinuous, entrances, expanding in the interior into broad lakes, completely sheltered. Of this type are the harbours of Havana, Santiago, Cienfuegos, Guantanamo, and many others.

*Climate.*—The climate may be characterized as tropic and insular. At Havana, on the north coast, the mean annual temperature is 77° F., with a range of but 11° between the mean temperature of the warmest and the coldest months. Inland and upon the south coast the temperature is probably somewhat greater, the climate of the north coast being tempered by the north-east trades, the prevailing winds. The mean annual rainfall at Havana is 52 inches, while inland it is probably greater, and upon the south coast less. About two-thirds of this precipitation falls between May and October, in what is known as the rainy season. The mean relative humidity at Havana is 75 per cent.

*Minerals.*—The mineral resources, so far as developed, are not of great importance. Iron ore of excellent quality is mined at several points between Santiago and Guantanamo, at the south base of Sierra Maestra. The ore, though abundant, is apparently float ore, mainly hæmatite, containing about 62 per cent. of iron. Most of the product has been shipped to the United States. A copper deposit in the neighbourhood of El Cobre, said to be of enormous value, was formerly extensively worked, but since 1868 mining upon it has ceased. Asphaltum has been found in several localities, and has for some time been used in the production of illuminating gas for the city of Santa Clara. Gold and silver were mined on a small scale in past times, but none is produced at present. There is, however, every probability that thorough prospecting will discover great mineral wealth.

*Forests.*—The forests are extensive and comprise many valuable species, among which are mahogany, ebony, cedar, walnut, lignum-vitæ, oak, and many species of palm. The prevailing tree is the Cuban pine, which forms excellent lumber. It is estimated that half the area of the island is forested. Little use is at present made of the forest wealth, and its economic development awaits the construction of adequate means of transportation.

*Government.*—For administrative purposes Cuba is divided into six provinces, which, named from the west eastwards, are Pinar del Rio, Havana, Matanzas, Santa Clara, Puerto Principe, and Santiago. These are divided into municipal districts, or *terminos*, of which there were 132 at the time of the census of 1899. These, in turn, are subdivided into *barrios*, or wards, of which there were between 1100 and 1200. There are no chartered cities, and the population of cities here given has been obtained from that of the *barrios*, which are closely built. On May 20, 1902, the military occupation by the United States, which had been the form of government since the war with Spain, formally ceased, and a Cuban Republic was inaugurated under American protection; the local administration was already then in Cuban hands.

*Population.*—The population in 1899, according to the census, was 1,572,797. In 1887 it was 1,631,687, and in 1877, 1,509,291. In the twelve years preceding the latest census there was an actual diminution of population of 58,890, a result of the civil war which opened in 1895. This measures, however, only a part of the loss consequent upon the war, since the population doubtless increased up to 1895. Allowing for this increase, the loss was probably about 200,000. The average number of inhabitants to a square mile was 36. The following table gives the population and its density by provinces :—

| | Population. | Inhabitants per Square Mile. |
|---|---|---|
| Havana | 424,804 | 153 |
| Matanzas | 202,214 | 55 |
| Pinar del Rio | 173,064 | 35 |
| Puerto Principe | 88,234 | 8 |
| Santa Clara | 356,536 | 37 |
| Santiago | 327,715 | 26 |

The proportion of urban population was very high, when it is considered that nearly all the industries and products relate to agriculture. Including all places of 8000 inhabitants or more, the urban population numbered 507,831, or 32·3 per cent. of all the inhabitants, a proportion very close to that of the United States. The proportion of urban inhabitants of the several provinces differed greatly :—

| | Per cent. Urban. |
|---|---|
| Havana | 65·4 |
| Matanzas | 28·8 |
| Pinar del Rio | 5·1 |
| Puerto Principe | 28·4 |
| Santa Clara | 22·5 |
| Santiago | 17·5 |

The principal cities, with their population in 1899, are as follows:—Havana, the capital of Cuba and of Havana province, population 235,981; Santiago, on the south coast, the capital of Santiago province, population 43,090; Matanzas, on the north coast, the capital of Matanzas province, population 36,374; Cienfuegos, in Santa Clara province, on the south coast, population 30,038; Puerto Principe, situated in the interior, the capital of the province of the same name, population 25,102; Cardenas, on the north coast in Matanzas province, population 21,940; Manzanillo, on the south coast, in Santiago province, population 14,464; Guanabacoa, in Havana province, population, 13,965; Santa Clara, in the interior, the capital of Santa Clara province, population 13,763; Sagua la Grande, on the north coast, in Santa Clara province, population 12,728; Sancti Spiritus, in Santa Clara province, population 12,696; Regla, a suburb of Havana, population 11,363; and Trinidad, on the north coast in Santa Clara province, population 11,120. As to sex, the population was divided in the proportions of 51·8 per cent. males and 48·2 per cent. females, the disproportion being due to immigration.

As to race, the whites constituted nearly 68 per cent., or more than two-thirds, and the coloured, including negroes, persons of mixed blood, and Chinese, 32 per cent. The following table gives the proportions of the races in the several provinces :—

| | Per cent. White. | Per cent. Coloured. |
|---|---|---|
| Havana | 74 | 26 |
| Matanzas | 60 | 40 |
| Pinar del Rio | 73 | 27 |
| Puerto Principe | 80 | 20 |
| Santa Clara | 70 | 30 |
| Santiago | 55 | 45 |

The proportion of coloured has been diminishing since 1841, when it was 58·5 per cent. The proportion of persons of alien birth was 9 per cent. of the population, and three-fourths of these were from Spain, China and Africa contributing largely to the remainder. As in other countries, the foreign-born were proportionately more numerous in the cities than in the country, nearly one-third of this element being found in the city of Havana. During the last six months of 1900 there were 15,810 immigrants, of whom 12,676 came from Spain, 979 from the United States, and 923 from Mexico. The conjugal condition of the people was in certain respects peculiar. Of the total population in 1899 only 15·7 per cent. were lawfully married. Besides these, 8·4 per cent. of the population were living together by mutual consent, in more or less permanent unions. The proportion of married, even with the addition of those in these consensual unions, was much smaller than in Europe. Consensual unions were much more common among the coloured than among the whites.

Of the population over ten years of age, 57 per cent. were unable to read, the proportions of illiterates in the two races being, whites 49·2 per cent., and coloured 72 per cent. The public school system, which under Spanish régime existed mainly on paper, has been put into effective operation under American administration. In 1899 the census reported that only 15·7 per cent. of the children of school age attended school, the proportion of whites being somewhat greater than that of coloured. The number of schools was 1510, the number of public and private schools being about equal. The number of teachers was 2665. In 1901 there were 3567 public schools, 3608 teachers, and 172,273 enrolled scholars.

Of the population over ten years of age, 51·2 per cent. were engaged in gainful occupations. The wage-earners were distributed as follows among the great groups of occupations :—

| | Per cent. of all Wage-Earners. |
|---|---|
| Agriculture, fishing, and mining | 48·1 |
| Domestic and personal service | 22·8 |
| Manufactures | 14·9 |
| Trade and transportation | 12·8 |
| Professions | 1·4 |

Practically the only religious sect represented in Cuba is the Roman Catholic, of which nearly all the people are, nominally at least, adherents.

There are no statistics of manufactures available, but it is well known that, aside from sugar mills and cigar factories, this branch of industry is of little importance.

*Agriculture.*—In 1899 there were 60,711 farms and plantations, comprising an area of 8,761,600 acres. Of this, 901,100 acres were under cultivation, or only 3·2 per cent. of the area of Cuba. The average size of farm was 144 acres, a little larger than in the United States; and the average area cultivated per farm was 15 acres. Of the cultivated area 43·5 per cent. was owned by the occupants, and 56·5 per cent. rented or worked on shares. Again, 84·9 per cent. was occupied by whites, and only 15·1 per cent. by coloured, or in mixed occupancy of white and coloured.

The following table shows the proportion of the cultivated area which was planted in each of the principal crops, this being the only measure of products which the census furnishes:—

| | Per cent of Cultivated Area |
|---|---|
| Sugar cane | 47·3 |
| Sweet potatoes | 11·3 |
| Tobacco | 9·3 |
| Bananas | 8·6 |
| Indian corn | 7·3 |
| Malangas | 3·4 |
| Yucca | 3·2 |
| Coffee | 1·6 |
| Cocoanuts | 1·4 |
| Cocoa | 1·4 |

Sugar, which is by far the most important crop, was produced in all parts of the island, but chiefly in Santa Clara and Matanzas provinces. Tobacco also was widely distributed over the island, but nearly three-fourths of the area devoted to it was in Pinar del Rio.

Live stock on farms is summarized as follows:—

| | |
|---|---|
| Horses | 88,001 |
| Mules and asses | 20,316 |
| Cattle | 753,300 |
| Hogs | 358,868 |
| Sheep and goats | 28,546 |
| Fowls | 1,517,892 |

The sugar mills of Cuba numbered 207, with a total capacity of 8,754,192 arrobas of cane, and a daily output of 61,407 bags of 200 pounds each of sugar. In connexion with these mills were 85 stills, with a daily capacity of 161,751 gallons of rum.

*Rail and Road.*—Means of transportation are scanty. Outside of the three smallest western provinces and the neighbourhood of large cities there is not a good road in Cuba, and many of the good roads are impassable in wet weather. There are about 1100 miles of railway, most of which are in Havana, Matanzas, and the western part of Santa Clara provinces. These railways are for the most part poorly constructed and scantily equipped.

*Commerce.*—The following figures epitomize the commerce of the island in 1899 and 1900:—

| | | | | |
|---|---|---|---|---|
| Total exports | (1899) | $46,301,929 | (1900) | $49,014,962 |
| Total imports | (1899) | 66,783,111 | (1900) | 66,658,589 |

*Leading Articles of Export.*

| | | | | |
|---|---|---|---|---|
| Sugar | (1899) | $19,876,749 | (1900) | $16,886,693 |
| Tobacco | (1899) | 21,084,750 | (1900) | 26,087,968 |
| Fruit and nuts | (1899) | 355,579 | (1900) | 729,719 |
| Wood (unmanufactured) | (1899) | 166,313 | (1600) | 1,050,322 |

| Countries. | Exports. | Imports. |
|---|---|---|
| United States | $33,356,889 | $29,176,002 |
| United Kingdom | 5,427,749 | 10,463,325 |
| Spain | 830,349 | 9,755,693 |
| Germany | 5,545,827 | 2,982,779 |
| France | 1,267,241 | 3,267,570 |

During the year 1900, 12,350 vessels, with a net tonnage of 4,928,814, entered the ports of Cuba, and 11,954 vessels, with a net tonnage of 4,367,246, cleared.

(H. G*.)

## II. Recent History.

The insurrection in Cuba from 1868 to 1878 was only the prelude to the stronger movement which began in 1895, and which was destined eventually to involve the United States in war with Spain, with the result of bringing to an end Spanish sovereignty in the island. In 1878 a policy of conciliation towards the insurgents was determined upon by the Spanish Government, and General Martinez Campos was despatched to Cuba to carry this new policy into effect. Martinez Campos commanded general respect, and found little difficulty in opening negotiations with the insurgents. Reforms in the administration and a free pardon for all who had taken part in the revolt were among the stipulations agreed upon, and the abolition of slavery was decreed, although this measure only took full effect in 1886. In the autumn of 1878 General Campos met the leaders of the insurrection at Zanjon; a treaty was signed embodying the various promises and conditions. It was the non-fulfilment of the terms of this convention (commonly called "El Pacto de Zanjon") which paved the way for the insurrection organized by José Marti in 1895. For all practical purposes there was no reform in administrative methods after the Convention of Zanjon. The island continued, as formerly, to be a rich field reserved for Spanish officialdom. Corruption became more pronounced. Cubans, unless entirely pro-Spanish, were given no share in the Government, although their standard of intelligence was quite equal to, if not higher than, that of the majority of Spaniards in similar conditions of life. In these circumstances the natives bitterly resented the attitude of the Spaniards, and the estrangement between the two peoples became more marked as time went on. In 1886 a number of young students were accused of writing some derogatory verses on the tombstone of a high Spanish official. The supposed ringleaders were arrested, and three of them were condemned to death and shot. It is difficult to find any excuse for this act, and it served to deepen into hatred and fear the hostility of a large section of the population to Spanish authority. Attempts at revolt were occasionally made, but without success, owing to prompt and drastic measures taken by the Government and to the lack of organization on the part of the Cubans.

**Circumstances leading up to the insurrection.**

Meanwhile the economic condition of the island was undergoing great changes. The crisis in the sugar trade in 1883, and the fall in prices in consequence of overproduction, seriously threatened the main industry. The situation was further complicated by the abolition of slavery, which involved severe pecuniary losses to the slave-owners. The energy shown by the people of Cuba at this crisis in their affairs is deserving of the highest praise. The old factories were abandoned and great central sugar-houses erected where the process of converting the cane juice into sugar could be more cheaply effected. The newest machinery was imported and immense areas of new cane fields were planted. The estates were mortgaged to obtain the money for these changes, and so by hard work and intelligent application the principal source of wealth was saved from annihilation and brought round to a comparatively flourishing condition. During this critical period the Spanish Government gave no helping hand. Heavy duties were levied upon Cuban products, although Spanish goods entering the island were allowed important reductions as compared with merchandise from other countries. Cuba was saddled with a gold debt of $162,849,625 for bonds issued in Spain to defray military expenses and other charges from which the island derived no benefit. The population of 1,500,000 souls was called upon to find a revenue of £5,240,000 sterling to meet the service of the bonds issued in Spain and to cover the expense of the Spanish administration of the island. In reality they paid much more than this amount, on account of the extortions systematically practised by the officials. The Cubans bitterly resented the attitude of Spain, but their protests were un-

heeded. Between the years 1889 and 1893 the sugar industry increased rapidly. A treaty with the United States allowing considerable advantages to sugars of Cuban origin was a substantial aid to the situation, and in the season 1893–94 the output amounted to 1,023,719 tons. Prices during this period of expansion had been fairly remunerative. In 1895, however, a change came for the worse. The treaty with the United States was denounced, and Cuban sugars entered only on the same terms as those from other foreign countries. The value of sugar all over the world fell steadily until it reached a price which left little, if any, profit to the producer. The factory owners, who had not had time to recoup themselves for the money which they had laid out in improvements, began to feel the strain severely, and numbers of the cane-growers abandoned their fields. As the economic crisis developed, real misery and hardship began to be felt in nearly every district.

The Government of Spain so far recognized the danger of the situation as to consider seriously the acceptance of some measure of reform. Señor Maura brought forward in the Cortes a project for restricted home rule for Cuba, but after long discussion it was rejected. A scheme of modified local government was then introduced by Señor Abarzuza and accepted; but this acceptance did not entail its immediate application to Cuba and Porto Rico, as the general public was induced to believe would be the case. Indeed, the measure was never applied to the Spanish West Indian colonies, being delayed on one excuse or another until the condition of Cuba had become such that the concessions proposed were inadequate. When conciliatory measures were tried in the island, a different law of constitution was promulgated. The opinion generally expressed in Cuba was that if Señor Abarzuza's proposals had been immediately put in force, the insurrection would not have broken out in 1895, or in any case would not have received the widespread sympathy which was accorded to it. Meanwhile a powerful factor was at work, the strength of which was too lightly estimated by the Spaniards. This was in the person of José Marti, a clever and intelligent man with the gift of oratory to aid him in his work. Love of Cuba, hatred of Spain, and a desire to see the island freed from Spanish domination led him to devote his whole life to pleading for the Cuban cause, and he ended by dying for the country he loved so well, shot down soon after the insurrection broke out. Marti began his work of organization after the Zanjon Convention had been signed. Meetings were held from time to time at Key West, Tampa, and all other places where Cuban colonies were established, and funds were collected for the purchase of arms and ammunition. Ultimately Marti decided to strike before the proposed Abarzuza reforms could be promulgated and the hostility of the Cubans towards Spain be in any degree modified by the concessions granted.

*Outbreak of the insurrection.*

José Marti had made plans for a simultaneous rising in the provinces of Santiago and Matanzas. In the former province 400 persons assembled in the neighbourhood of Yara, and on February 23, 1895, took up arms under the leadership of Jésus Rabi. The movement in Matanzas was attempted on the same day, but was mismanaged at the start and suppressed for the moment. The Government from the first underestimated the sympathy of the public with the outbreak, and declared that it was nothing more than an attempt by a few bandits to commit robbery and outrage under the guise of patriotism. How fallacious was this reasoning soon became apparent from the eagerness shown by people of all classes in watching the progress of events in Santiago. Perhaps the most significant fact in connexion with the revolt was that it was not a *pronunciamiento* of any particular leaders, but the spontaneous uprising of people belonging to the lower classes, without distinction of colour. At the outset the whites were in the minority, hence the mistaken opinion was almost invariably held outside Cuba that the trouble was one of negroes against white men. At the beginning of 1895 Spain had in Cuba a garrison of some 17,000 men, a force amply sufficient to have crushed the revolutionary movement had it been energetically handled. The officials, however, made hardly any effort to disperse the rebels, whose ranks were rapidly increasing, and before the end of March 1895 it was evident that serious trouble was in store for Spain. The Madrid Government raised the garrison of Cuba to a strength of 30,000, and appointed General Martinez Campos as Captain-General of the island. After his arrival in Cuba in April, General Campos found that his hands were tied by the many restrictions imposed from home, and that he would not be permitted to declare in force the Abarzuza reforms until the insurrection was suppressed. The Spanish troops were in a demoralized condition, and the character of the eastern portion of Cuba made military operations difficult.

On April 21, Antonio Maceo, who afterwards played so important a part in the revolt, landed at Duabi, and shortly afterwards was followed by Maximo Gomez, accompanied by Marti. Maceo was a mulatto, and his presence in Cuba at once drew many additional recruits to the insurgent ranks from the coloured population. Maximo Gomez was a native of San Domingo, and had served in the Spanish army during the campaign in that island. Both Gomez and Maceo had taken part in the insurrection of 1868–78, and won for themselves a considerable amount of prestige. To Gomez was confided the post of Commander-in-Chief of the rebel forces, while Maceo was appointed next to him in rank. Marti prepared to return to New York to procure further supplies of arms and ammunition, but on his way to the seacoast he was killed in a skirmish with Spanish troops. His death was a severe blow to the Cuban cause, but the progress of the rebellion continued unchecked. In every town in Cuba secret committees were formed to aid the revolt, and by the month of August Gomez and Maceo had under their orders some 4000 men, and the area of the movement had extended over the whole of the province of Santiago and the greater part of Puerto Principe. Realizing the gravity of the situation, the Captain-General explained to the home Government that it would be necessary to occupy every province of the island and vigorously attack the insurgents in the field. In response to his demand for reinforcements, troops were poured into the island, but they consisted mainly of young and raw recruits, and sickness set in among them to an alarming extent. The wet season, furthermore, rendered any active operations almost impossible. At the close of 1895 the Spanish army in Cuba, including the volunteers and irregular cavalry under arms, numbered 100,000 men. The rebel forces had also steadily increased, and amounted to 10,000, but they were very imperfectly supplied with arms and ammunition.

The condition of the Spanish army was far from satisfactory. The men were obedient and cheerful, but were young, inexperienced, unacclimatized, poorly fed, and badly looked after. No attempt was made to instruct officers or men in their duties, or to improve the musketry practice. The officers were generally ignorant of the topography of the island, and took no trouble to make proper reconnaissances. Such maps as were compiled by order of the Government were so inaccurate as to be of small practical value. In these circumstances it is no wonder that the insurgents were able to elude pursuit and constantly to lead the Spanish troops into carefully prepared

ambushes. The organization of the insurrection developed rapidly. A provisional Government was formed, and the Marquez de Cisneros was named President of the Cuban Republic. The island was divided into districts, and a civilian appointed prefect of each one. Certain taxes were levied by these rebel authorities, non-payment being punished by destruction of the plantation buildings or crops of standing cane and the seizure of cattle and other live stock. Meanwhile the Cuban Junta in New York continued to collect subscriptions and arrange for further supplies of arms.

In January 1896 the insurgent leaders determined to carry the war into the districts in the immediate vicinity of Havana, and so paralyze the industrial life of the island. The Spaniards gave little heed to the rumours concerning the movement, and failed to perceive that the majority of the population sympathized with the rebels. As the insurgents advanced, they burned all the cane-fields and destroyed valuable property, on the ground that as long as industry continued to flourish in Cuba, the Spanish Government could find the money to maintain a large army to operate against the Cubans, but that once the industrial life was stopped, Spain would be unable to bear the burden and would then withdraw her troops. Accordingly, a vast sheet of flame from the burning cane-fields marked the advance of the insurgents. Near Coliseo, in the province of Matanzas, General Campos made his last effort to stem the onward movement with 10,000 men, but the insurgents eluded him and invaded the rich Western Provinces. The town of Havana was thrown into a state of excitement, and Marshal Campos was relieved of his command.

***General Weyler sent out.***

At the opening of 1896 there were still many Cubans in sympathy with, or actively engaged in, the insurrection who would have been satisfied with a liberal measure of home rule, and this aspect of the case was duly impressed upon the Spanish Government, but to no purpose. Meanwhile in the United States the drift of feeling was distinctly in favour of the insurgents, and this had the effect of making Spain more determined than ever to crush the revolt by force of arms, and the task was entrusted to General Weyler, who had a great reputation for energy and relentless severity. Large reinforcements were sent to the island from Spain, and in a few months the army of occupation amounted to 185,000 regular troops, 20,000 guerillas, and 30,000 volunteers. Antonio Maceo, with some 4000 insurgents, had taken up his position in the mountains of Pinar del Rio, and continually harried the Spanish garrisons. In order to prevent him from recrossing towards the eastern provinces and again joining hands with Gomez, a cordon of troops was stationed from north to south of the island between Mariel and Majana, trenches were thrown up, entanglements laid down, and blockhouses erected at short intervals. A corps of 20,000 men was stationed on this *trocha* or military cordon, and 10,000 troops were despatched to Pinar del Rio to march through the province and force a fight with the followers of Maceo whenever possible. These measures did not give the results expected. The rainy season brought sickness among the troops on the *trocha*, and many thousands died of fever, dysentery, and exposure. The columns sent out in Pinar del Rio were exhausted by long marches, and invariably found the mountain passes difficult of approach and strongly guarded by the rebels. Foiled in his attempt to bring about a general engagement, General Weyler issued an order for the "concentration" of the whole rural population in the fortified towns, with a view to prevent the insurgents from obtaining supplies from the country people with them. Some 600,000 people, chiefly women and children, were thus driven from their homes and collected in the towns, where they had no means of gaining a living, and where no due provision had been made for their subsistence. With very few exceptions the men joined the insurrection, and the women and children suffered great privations.

***American grievances against Spain.***

In June 1896 a vessel called the *Competitor* was surprised and captured on the north coast of Pinar del Rio just after landing a cargo of arms and ammunition for Maceo. The crew, with one exception, were United States citizens. They were tried by a military tribunal and sentenced to be shot. Under the treaties existing between Spain and the United States it was specially provided that unless American citizens were captured *with arms in their hands* against the Spanish authority, they could only be arraigned before the ordinary tribunals. The United States Government insisted that these men were not captured with arms in their hands within the meaning of the treaty, and that the summary trial accorded them was illegal. The Spanish authorities maintained that they had right on their side, but at the last moment gave way and ordered a fresh trial by ordinary process. The men were in prison for a long period, but were finally released and sent out of the island. Here the affair nominally ended, but bad blood was created between the two nations. One of the most difficult political questions with which General Weyler was confronted was the treatment of United States citizens in Cuba. Of persons born in the United States there were only a limited number in the island, but of Cubans who had become naturalized citizens of the United States there were some 20,000, and it was this latter class who occasioned friction. It was a common practice for Cubans to reside a sufficient length of time in the United States to obtain naturalization papers, then to return to Cuba and, whenever in trouble, to call upon the United States authorities for assistance. Many of these naturalized citizens who were directly or indirectly implicated in the revolt only owed their immunity from imprisonment to the fact that their arrest would have entailed diplomatic complications with the United States. Occasionally a man was arrested who claimed to be an American citizen; he could talk no language but Spanish, was born in Cuba, and had not been near his adopted country for twenty years; nevertheless he was entitled to and received the active intervention of the United States Consul-General in Havana. Time after time the Spanish authorities were forced to give way to the protests sent from Washington, and each succeeding incident increased the bitterly hostile feeling of the Spaniards towards the United States.

In July 1896, José Maceo, who commanded the rebels in the eastern part of the island, was killed in a skirmish. This loss to the cause was more than compensated for by the landing of Calixto Garcia, a veteran of the former revolt, who became one of the most prominent of the rebel leaders. Garcia had studied military tactics and understood the weak points of the Spanish character. Many members of families of good social standing who had hesitated to serve under Gomez or Maceo, joined Garcia in the field, and the movement in Santiago and Puerto Principe was further strengthened by the landing of arms and ammunition sent by the Cuban Junta in New York. In the month of August an attempt was made to dislodge Antonio Maceo from the mountain heights near Cacarajicara, in the province of Pinar del Rio. The officer commanding the Spanish troops, General Echagüe, was severely wounded, and the Spanish loss was heavy. After hard fighting, the insurgents were forced to retire farther into the mountain fastnesses. In November the strength of the insurrection in Pinar del Rio and the centre of the island showed no sign of exhaustion, and General Weyler

himself took the field with 60,000 men. Shortly before he left on this expedition he repeated his proclamation that a free pardon would be extended to all insurgents who presented themselves to the Spanish authorities. The rebels did not, however, take advantage of this concession, except in the case of sickness, and in that event left the revolt with the advice and consent of their comrades. An order was issued from the military headquarters to the effect that troops when marching through the country would destroy all buildings or crops capable of sheltering or assisting the insurgents in any way, and that all persons encountered who had failed to obey the order to concentrate in the fortified towns were to be treated as rebels. This roused the indignation of the people of the United States, for it showed clearly that the policy Weyler intended to pursue was one of absolute extermination of the recalcitrant sections of the population. The horrors of the march through the provinces of Havana and Pinar del Rio cannot be overestimated. The country people were mercilessly shot down, the animals that could not be made use of were hamstrung, and the smiling country was left a grim mass of smoking ruins. Constant skirmishes occurred with groups of insurgents, but no advantage of importance was gained.

*Weyler's severity.*

Suddenly it was discovered that Antonio Maceo was not in Pinar del Rio, but had slipped through the *trocha* and was in the province of Havana, in the rear of Weyler. Maceo had crossed the Bay of Mariel in a boat with the object of organizing a demonstration and threatening the city of Havana as an offset to the operations of Weyler in Pinar del Rio. This intention was never put into practice for the reason that on December 6 Maceo was killed in a skirmish. His death was a very severe blow to the insurrection, and the Spaniards thought for a time that they would have small further difficulty with the rebels. But here, again, the authorities underestimated the strength and bitterness of feeling on the part of the Cubans. After a few weeks Rius Rivera, who had served throughout the former revolt, landed in Pinar del Rio to take command of the rebels, but in March 1897 he was wounded in a skirmish near San Cristobal, and subsequently captured and deported. About the same time, Layas, another prominent Cuban leader, was killed in the province of Havana, but these two additional difficulties did not cause the insurgents to waver.

General Weyler returned to Havana after the death of Maceo, leaving General Arolas and General Bernal to continue operations against the rebels in Pinar del Rio. Other factors arose to complicate the situation. The authorities declared that the owners of sugar plantations were making regular payments to the rebel leaders in order to protect their property. No doubt it was a fact that such payments were made, but no other course was open to the planters unless they were prepared to abandon their properties. General Weyler issued a decree prohibiting the manufacture of sugar until such time as the different districts might be declared pacified, and stating that work would only be permitted as this pacification progressed. This order affected Spaniards as well as Cubans, and brought upon Weyler a storm of abuse, so much so that he was obliged to rescind the decree. Large numbers of persons suspected of sympathizing with the rebels were arrested and shipped without trial to the Spanish penal settlements of Fernando Po and Ceuta, in Africa, and executions after summary trial took place almost daily.

The Spanish Commander-in-Chief decided to build a second *trocha* across the island for the purpose of isolating the central provinces from the eastern section of Puerto Principe and Santiago, drawing the line from Moron on the north coast to Jucaro on the southern seaboard. Preparatory to initiating this work, General Weyler determined to march through the centre of the island in order to drive the insurgents towards the east, and with this object left Havana early in February 1897 at the head of a large body of troops. The route taken was through Havana and Matanzas to Santa Clara and Cienfuegos. The system followed was similar to the former one through Pinar del Rio. The insurgents made no attempt to oppose the troops, and their inactivity apparently deceived General Weyler, for on his return to Havana he declared officially that the western and central sections of the island might be considered pacified. This statement was no sooner made public than the rebels again began to make their presence known by attacks on Spanish posts and the destruction of a number of plantations where the owners had failed to comply with their demands.

The arrest of an American citizen named Rius served to increase the tension between the United States and Spain. Rius was a Cuban who had obtained naturalization after residing for some years in Philadelphia. The United States Consul-General demanded that he should be immediately tried and released if no offence could be proved against him. While the question was pending, Rius was reported to have died suddenly. The United States Consul-General insisted upon a medical examination of the body, and it was found that Rius had died from the effects of a blow on the back of his head. On the woodwork of a chair in his cell was discovered a statement, scratched with a nail, to the effect that the prison authorities intended to murder him. General Lee, the United States Consul-General in Havana, reported the facts of the case to Washington, and President Cleveland caused instructions to be sent to him to demand a full investigation, promising all necessary support. Ultimately the Spanish authorities appointed a commission of inquiry, but no clear proof was adduced that Rius had been deliberately murdered. The incident then dropped, but it brought one step nearer the intervention of the United States.

Meanwhile the country-people of Pinar del Rio, Matanzas, and Havana, concentrated in the fortified towns, were dying of starvation. In the village of Consolacion del Sur the deaths exceeded 10,000, and in the city of Matanzas the total was still larger. As the true situation became understood in the United States, the opinion that intervention should take place, or in any case the recognition of Cuban independence, every day found expression in emphatic terms in Congress. The number of lives sacrificed in the campaign had reached nearly 50,000 without bringing the end of the trouble in sight, while the cost of the operations in Cuba was calculated at £2,000,000 sterling monthly. In view of the general situation, the United States Government approached the Madrid authorities with suggestions for a very liberal measure of local self-government for Cuba. This pressure from Washington, combined with a change of Ministry in Spain, brought about the recall of General Weyler in October 1897, and the appointment of General Blanco as his successor. The Sagasta Administration determined on a radical change of policy in Cuba and Porto Rico. The Abarzuza reforms were abandoned, and a form of Constitution was drawn up for both islands based on that of Canada, but with certain restrictions as regards financial legislation. General Blanco was instructed to use every endeavour to conciliate the Cubans, but the new policy came too late. The Cubans were convinced that it was only a question of maintaining the insurrection for another year to force Spain to evacuate the island, unless American intervention brought about

*Recall of Weyler.*

this result at an earlier date, and the principal rebel leaders declined to accept the terms offered.

***General Blanco's policy.***

General Blanco arrived in Cuba in November 1897, and immediately annulled the concentration order; but the permission for the people to return to their homes was of little avail to them owing to their weak condition and the ruin of their homes. To the insurgents in the field the abrogation of the concentration decree was, however, an immense boon. They were now able through their friends in the cities to obtain the medicines, clothing, and other necessaries of which they stood sorely in want. General Blanco's next act was to proclaim an amnesty for all rebels who presented themselves to the authorities. A few surrendered, but no leaders of importance. No further executions of captured rebels took place, and arrests for political purposes were rarely effected. The Press, also, was allowed a far greater degree of liberty, although all news concerning the revolt continued to be strictly censured. On January 1, 1898, the new Constitution was proclaimed in force and a Colonial Government appointed, of which Señor Galvin was the nominal leader. The new Administration had, however, very little power, the question in Cuba being a military one as long as the insurrection continued. Finding that the insurgents did not intend to lay down their arms, General Blanco ordered military operations to be energetically carried out; but, as in former years, no decided advantage over the rebels was gained.

***The "Maine."***

A riot, in which many military officers and Spanish volunteers were concerned, occurred in Havana in January, and with a view to the protection of citizens of the United States in the event of any further outbreak the American warship *Maine*, commanded by Captain Sigsbee, was ordered to Havana. Under the direction of the port authorities she was moored in the section of the harbour specially reserved for men-of-war. No discourtesy was shown to the officers and crew of the vessel, and several receptions were held on board by the captain and officers in order to return in some measure the hospitality extended to them by the residents of Havana. On February 15 a large number of guests visited the cruiser. At 9.30 on the evening of that day the inhabitants of Havana were startled by a terrific explosion, and the *Maine* was seen to be in flames and in a sinking condition. Subsequent explosions of ammunition occurred, and the wreck settled down. The boats of the Spanish cruiser the *Alfonso XII.* were promptly lowered, and helped to save the survivors. The complement of the *Maine* in officers and crew was 347 all told. Two officers were absent on leave ashore when the explosion occurred. Of those on board, two officers and 257 men lost their lives. The great loss of life among the crew was due to the fact that the men had turned in, and the explosion took place under their quarters in the forward part of the vessel. Everything that was possible was done by the Spanish authorities to aid the wounded survivors, seven of whom afterwards died. A public funeral was accorded to the victims, and was attended by the principal Spanish officials. In spite of this show of sympathy, it was recognized in Havana that the critical moment had arrived, and that unless the explosion could be satisfactorily accounted for, war between Spain and the United States was inevitable.

Shortly before the disaster two events had occurred rendering the relations between the two countries extremely strained. The first was a letter written by Señor Dupuy de Lome, the Spanish Minister in Washington, to his friend Señor Canalejas, then on a visit to Cuba. It was not intended for publication, but was stolen in Havana and disposed of to a New York newspaper. In this letter the Minister expressed emphatic doubts as to the good faith of the United States Government in dealing with the Cuban question, and made some insulting remarks in reference to President M'Kinley. The result of the publication of this letter was that Señor Dupuy de Lome was forced to resign his post. The second event was a request from Madrid for the recall of General Fitzhugh Lee from his position as Consul-General of the United States in Havana, on the ground of his being a *persona non grata* to the Spanish authorities.

***The "Maine" inquiry and its conseqences.***

The advice of Captain Sigsbee to his Government and the people of the United States was contained in a telegram sent to Washington a little before midnight on the evening of the disaster,—"Suspend judgment pending result of official investigation." A court of inquiry was named, composed of Captain (afterwards Admiral) W. T. Sampson, Captain F. C. Chadwick, Lieutenant-Commander W. P. Potter, and Lieutenant-Commander A. Marix. The court assembled on board the United States steamer *Mangrove* in Havana harbour a few days after the disaster occurred, and sat continuously until March 21. The hull of the *Maine* was examined by divers, and a searching investigation of all facts bearing on the case was made. It was not until early in April that the report of the court was handed to Congress. The finding was:—

"That the loss of the *Maine* was not in any respect due to fault or negligence on the part of any of the officers or members of her crew; that the ship was destroyed by the explosion of a submarine mine, which caused the partial explosion of two or more of her forward magazines; and that no evidence has been obtainable fixing the responsibility for the destruction of the *Maine* upon any person or persons."

The position of the vessel after the explosion was evidence of the correctness of this finding, the keel being bent upwards from the centre and remaining above the level of the main deck. The Spanish authorities held an inquiry, and after a few days drew up a report to the effect that the explosion was due to internal causes. They also stated officially that no submarine mines existed in the harbour of Havana, and that the Government possessed no materials for their construction. This statement was afterwards conclusively proved to be incorrect.

***President M'Kinley's message.***

On April 8, 1898, General Lee received orders to leave Cuba and hand over the charge of United States interests to the British Consul-General. The following day General Lee, with the remainder of the United States citizens still in Havana, embarked on board a United States gunboat and proceeded to Florida, and on Monday, April 11, President M'Kinley sent to Congress his Message on the situation. On April 13 the Foreign Affairs Committees of both Houses reported joint resolutions, and on April 18 a conference between the two Committees resulted in the adoption of the following joint resolution by 42 votes to 35 in the Senate, and by 311 votes to 6 in the House of Representatives:—

"Whereas the abhorrent conditions which have existed for more than three years in the island of Cuba, so near our own borders, have shocked the moral sense of the people of the United States, have been a disgrace to Christian civilization, culminating as they have in the destruction of a United States battleship with 266 of its officers and crew, while on a friendly visit in the harbour of Havana, and cannot longer be endured, as has been set forth by the President of the United States in his Message to Congress of April 11, 1898, upon which the action of Congress was invited; therefore,

"Resolved by the Senate and House of Representatives of the United States of America in Congress assembled—

"*First.* That the people of the island of Cuba are, and of right ought to be, free and independent.

"*Second.* That it is the duty of the United States to demand, and the Government of the United States does hereby demand, that

the Government of Spain at once relinquish its authority and government in the island of Cuba and withdraw its land and naval forces from Cuba and Cuban waters.

"*Third.* That the President be, and hereby is, directed and empowered to use the entire land and naval forces of the United States, and to call into the actual service of the United States the militia of the several States, to such an extent as may be necessary to carry these resolutions into effect.

"*Fourth.* That the United States hereby disclaims any disposition to exercise sovereignty, jurisdiction, or control over the said island, except for the pacification thereof, and asserts its determination when that is completed to leave the government and control of the island to its people."

This resolution was signed by President M'Kinley on April 20, and a copy served upon the Spanish Minister, Señor Polo y Bernabé, who immediately asked for his passports and left Washington. On April 24 the Spanish Government formally recognized the existence of war between Spain and the United States, and on April 25 the United States Congress passed the following Bill without a division :—

"Be it enacted by the Senate and House of Representatives of the United States in Congress assembled, *First*—That war be, and the same is hereby declared to exist, and that war has existed since the 21st day of April A.D. 1898, including the said day, between the United States of America and the kingdom of Spain. *Second*—That the President of the United States be, and he hereby is, directed and empowered to use the entire land and naval forces of the United States, and to call into the actual service of the United States the militia of the several States, to such extent as may be necessary to carry this act into effect."

On April 21 the President of the United States proclaimed the blockade of the Cuban coast from Cienfuegos on the south of the island, thence westwards to Cape San Antonio and thence to the east, passing Havana, to Cardenas on the northern seaboard. From the date of the destruction of the *Maine*, the bulk of the United States navy had been quietly concentrating at Key West, off the coast of Florida, and within eight hours of the proclamation of the blockade the fleet was patrolling Cuban waters. The dominion of Spain in Cuba virtually ceased from this time.

Meanwhile General Blanco decided to make a bold bid for peace with the insurgents, and for their co-operation with the Spanish troops in defending the island against American aggression. On April 10, 1898, he ordered a cessation of hostilities against the rebels, and sent a deputation to their leaders to ascertain what terms they demanded as the price of laying down their arms. The insurgents accepted the armistice offered pending any decided action on the part of the United States, but made no compact with the Spanish authorities not to resume hostilities on the declaration of war, and meanwhile remained in their camps awaiting the development of events. General Blanco withdrew the majority of the garrisons in the interior of the island in order to strengthen the coast defence against any attack by the Americans, and the country districts were left at the mercy of the insurgents. When the declaration of war was made public on April 23, the insurgents immediately resumed their aggressive tactics and harassed the Spanish troops when opportunity offered. Considerable supplies of arms, ammunition, and provisions were despatched by the United States Government to enable the insurgents to carry on operations until the time arrived for the landing of American troops. With a few exceptions, there was at this time no industrial life in the island; it had been reduced to a desert, and on all sides were signs of suffering and distress.

The United States army for the invasion of Cuba was concentrated at Tampa, in Florida, in May 1898. It had been intended to land a force of 5000 men, under the command of Major-General Shafter, near Tunas, on the south coast, and, in conjunction with the insurgents, gradually push the Spaniards to the westward, but the arrival of a Spanish squadron under Admiral Cervera at Santiago de Cuba, and the blockade of that port by Admiral Sampson, made imperative the landing of an army to attack the city, and so render the harbour untenable for the Spanish ships. On June 14 the Fifth Army Corps, consisting of 815 officers and 16,072 men, sailed from Tampa. Shortly before this the transport *Florida* had landed a contingent of 500 Cubans on the north coast of the island. On June 20 the fleet of transports conveying the American troops arrived off Daiquiri, some 15 miles to the east of the city of Santiago, and by the evening of the 24th the entire force had been landed. On the following day, under an arrangement effected by Major-General Shafter, some 5000 Cubans, commanded by Calixto Garcia, were also brought to the scene of operations. No attempt was made by the Spaniards to resist the landing, although the country lent itself admirably to defensive purposes. The garrisons at Daiquiri and Siboney retired in the direction of Santiago, where General Linares was in command of some 7000 men. At Guantanamo, a few miles to the eastward of Daiquiri, a force of some 1400 American marines had been landed a couple of weeks earlier, and held possession of the villages at the entrances to the harbour.

***After the declaration of war.***

Until June 30, Major-General Shafter was engaged in moving his troops towards Santiago, and preparing for a general attack on the outer lines of defence at San Juan and El Caney. The Cubans were usefully employed as scouts and skirmishers. On July 1 the division commanded by General Lawton attacked El Caney. The Spaniards made an obstinate resistance, but their positions were captured. General Vara del Rey, commanding the Spanish forces, and most of his officers were killed. At the same time the divisions under Generals Wheeler and Kent drove the Spaniards from the hill of San Juan, which formed part of the outer line of defence of Santiago. During the night the Spanish General Escario reached Santiago with reinforcements of 3600 men, having made forced marches from Manzanilla. The fighting was continued on the following day, the American lines being drawn closer towards Santiago. On the morning of July 3 (an unsuccessful, but plucky, attempt having been previously made by Lieutenant Hobson to block the channel by sinking the *Merrimac* across it) the Spanish squadron under Admiral Cervera left the harbour and attempted to force the blockade. In half an hour this important section of Spain's navy was destroyed, with a loss of 600 killed and 2000 captured, and the fate of Santiago was sealed. At noon General Shafter demanded the unconditional surrender of the city. General Linares had been wounded on July 2, and had temporarily handed over the command to General Toral, who conducted the negotiations with General Shafter. After a delay of fourteen days and a partial bombardment of the city on July 12, the Spaniards agreed to the terms proposed, namely, the surrender of the city and province of Santiago de Cuba and the entire garrison of the province, this consisting of nearly 23,000 officers and men. The losses of the United States troops in the fighting on July 1, 2, and 3 were officially returned as 22 officers and 208 men killed, and 81 officers and 1203 men wounded, while 79 men were reported missing. The Spanish loss was stated to be, approximately, 1500 officers and men killed and wounded.

General Shafter took formal possession of Santiago on July 17. By some oversight, no official invitation to be present at the ceremony of surrender was extended to Calixto Garcia as representative of the Cubans. This fact, and the order of General Shafter prohibiting the Cubans

from entering the city, were taken as an insult by Garcia, and he withdrew with all his forces to the interior of the island in the direction of Holguin, where he remained until hostilities were suspended.

The sufferings of the non-combatants in Santiago were very great. The foreign Consuls, of whom the British Consul, Mr Ramsden, was the *doyen*, visited the American lines on July 3 and presented a joint petition to General Shafter to the effect that the women, children, and other non-combatants should be allowed to leave the town before further offensive operations were undertaken. This request was granted, and El Caney was designated as the most convenient place to which these people might proceed. Some 22,000 persons took advantage of the permission. The Spanish authorities placed no obstructions in the way, but only allowed the fugitives to take with them such food and worldly goods as they could carry individually, and would permit no wheeled vehicles to leave the city. In the course of a couple of days the food supplies at El Caney were exhausted, and it became necessary for General Shafter to issue rations. These were necessarily limited, and many families were reduced to dire straits. Mr Ramsden died shortly afterwards from the effects of the privations he suffered at this period.

Some further skirmishing took place towards the end of July, and the Spanish gunboats in the harbour of Manzanilla were captured or destroyed by United States men-of-war. The fall of Santiago, however, practically ended the war. On July 26 the French Ambassador in Washington approached the United States Government with peace proposals. A protocol was signed on August 12, and all hostilities were suspended. Under the terms of this agreement Spain was obliged to evacuate Cuba within a reasonable time, as is seen by the following copy of the official document signed by Mr W. R. Day, the Secretary of State, and M. Jules Cambon, the French Ambassador, acting on behalf of the Spanish Government:—

"Protocol of agreement between the United States and Spain, embodying the terms of a basis for the establishment of peace between the two countries.

"William R. Day, Secretary of State of the United States, and his Excellency Jules Cambon, Ambassador Extraordinary and Plenipotentiary of the Republic of France at Washington, respectively possessing for this purpose full authority from the Government of the United States and the Government of Spain, have concluded and signed the following articles embodying the terms on which the two Governments have agreed in respect to the matters hereinafter set forth, having in view the establishment of peace between the two countries, that is to say:—

"Article I. Spain will relinquish all claim of sovereignty over, and title to, Cuba.

"Article II. Spain will cede to the United States the island of Porto Rico and other islands now under Spanish sovereignty in the West Indies, and also an island in the Ladrones, to be selected by the United States.

"Article III. The United States will occupy and hold the city, bay, and harbour of Manila pending the conclusion of the treaty of peace, which shall determine the control, disposition, and government of the Philippines.

"Article IV. Spain shall immediately evacuate Cuba, Porto Rico, and other islands under Spanish sovereignty in the West Indies; and to this end each Government will, within ten days after the signing of this protocol, appoint Commissioners, and the Commissioners appointed shall, within thirty days after the signing of this protocol, meet at Havana for the purpose of arranging and carrying out the details of the aforesaid evacuation of Cuba and the adjacent Spanish islands; and each Government will, within ten days of the signing of this protocol, appoint other Commissioners, who shall, within thirty days after the signing of this protocol, meet at San Juan, in Porto Rico, for the purpose of arranging and carrying out the details of the aforesaid evacuation of Porto Rico and other islands now under Spanish sovereignty in the West Indies.

"Article V. The United States and Spain will each appoint not more than five Commissioners to treat of peace, and the Commissioners so appointed shall meet in Paris not later than October 1, 1898, and proceed to the negotiation and conclusion of a treaty of peace, which treaty shall be subject to ratification according to the respective constitutional forms of the two countries.

"Article VI. Upon the conclusion and signing of this protocol, hostilities between the two countries shall be suspended, and notice to that effect shall be given as soon as possible by each Government to the commanders of its naval and military forces.

"Done at Washington, in duplicate in English and in French, by the undersigned, who have hereunto set their hands and seals, the 12th day of August 1898.

(Seal) William R. Day.
(Seal) Jules Cambon."

The treaty of peace agreed upon in Paris was finally signed on December 10, 1898, and Spanish dominion ceased after having been in force since 1492, a period of 406 years.

It is worthy of note that throughout the insurrection the Church took no part in the political troubles; this was in marked contrast to the attitude of the Clerical authorities in the Philippines and in Spain.

(C. E. A.).

**After cessation of Spanish-American hostilities.**

By the terms of the Spanish surrender of Santiago province, July 1898, that province temporarily became American territory. The remainder of Cuba was still in a state of insurrection, and under Spanish control. The Porto Rico campaign after the fall of Santiago lasted until the signing of the protocol on 12th August 1898. The status of the Cuban insurgents, who were still in arms against Spain, west of Santiago province, remained indefinite. Inasmuch as by the terms of the protocol Spain relinquished all claims to sovereignty and title to Cuba, and promised to evacuate the island as soon as a Commission to be appointed should arrange details of the evacuation, the insurgents themselves, exhausted by the conflict, naturally ceased hostilities, awaiting future action. Within a month of the surrender of Santiago all the Spanish and American forces, with the exception of a small guard of the latter, had returned to their homes. Brigadier-General Leonard Wood was appointed Military Governor of the stricken province. He at once began an enlightened policy of sanitation and public improvements, and gave the Cuban element every official and political recognition. The undertaking of the United States to retain control only until a form of government could be evolved from the chaotic and stricken condition existing upon the island at the end of hostilities was conscientiously maintained. No discrimination was allowed in favour of goods shipped to Cuba from the United States, and the products of all nations were admitted to Cuba on same terms as America. The acts of the temporary American occupation were: (1 the relief of immediate suffering; (2) the successful conducting of an orderly evacuation of the island by Spain without the attending evil of anarchy; (3) the disbandment of the Cuban army; (4) the restoration and betterment of the social, hygienic, and economic condition; and (5) the preparation of the island for independent government.

The condition of the island upon the cessation of hostilities was bad beyond description. The people were impoverished by revolution and starvation, transportation and communication were palsied, agriculture prostrated, brigandage rampant, and commerce dead. Human misery had apparently attained the maximum of possibility. The débris of war and attending disease existed everywhere. Official and private charity immediately hastened to the relief of the starving inhabitants, and was practised upon a scale of munificence never before exhibited in the world. Money, food, medicine, raiment, shelter, and employment were quickly bestowed, all dependants were properly cared

for by the public treasury, and the hordes of maimed beggars which hitherto had infested the streets of Cuban cities were properly dealt with. The relinquishment of Spanish sovereignty was accomplished in an orderly manner and without disturbance on January 1, 1899. By previous arrangement the flag of Spain was lowered and that of the United States temporarily hoisted. The Spanish officials withdrew from the island and the American authorities took up the reins of government. A tragic incident of the evacuation of Cuba, the last colony of Spain in America, was the solemn removal of the supposed remains of Christopher Columbus, the discoverer of America and founder of the first Spanish-American colony, from their tomb in the Cathedral at Havana, and transportation to Spain.

Another serious problem which confronted the American authorities upon the acquirement of Cuba was the disbandment of the Cuban army. It was unfortunate that the tidings of peace in Cuba should have been followed by distrust between the Cubans and Americans, and a mutual misunderstanding followed which for some time proved awkward. This was brought about (see p. 309) by the refusal of the American commander at the battle of Santiago to permit the representatives of the Cuban army under General Calixto Garcia to participate in the investment of that city. The Cubans were hurt and insulted, feeling that there had merely been a change of masters. General Garcia, wounded by the incident, retired with his troops into the interior of Santiago province. In October 1898 the Provisional Cuban (Insurgent) Government, which had existed since 1895, called a meeting of delegates from all sections of the insurgent forces to decide upon a line of policy for the immediate future. This Congress sat at Santa Cruz del Sur for some three weeks. It was finally resolved to dissolve the Provisional Government and nominate a Commission to represent the armed forces which had fought against the Spaniards, leaving the question of the constitution of a Government to be determined at a later period, when the intentions of the United States Administration in the matter of Cuba were more clearly defined. This Commission, the President of which was Calixto Garcia, went to Washington in December 1898 and laid before the United States authorities a carefully prepared statement of the situation of Cuba and the Cubans. The Commission arranged that the Insurgent army be disbanded, with certificates of service to be presented to the future permanent Government of Cuba for pay. General Garcia, at the head of the Commission, declared that the Cubans accepted gratefully the aid of the United States, and trusted implicitly in its promise that a free and independent Government should sooner or later be established in Cuba. This general, who for forty years had laboured and fought for the freedom of Cuba, died in Washington, December 1898, while upon this mission of peace. The American Government sent his remains to Cuba upon a man-of-war, and accorded them full military honours. After the death of Garcia, the details of disbanding the Cuban army became temporarily serious, and resulted in many conferences between the military authorities and the insurgent leaders in Cuba. Finally, through the aid of General Maximo Gomez, all the various elements came to agreement, rosters were made of the insurgent armies, and each soldier was given a sum of money sufficient for his temporary needs, and the arms turned over to the American authorities. In all $3,000,000 was distributed to 48,000 men and 6000 commissioned officers.

By the Treaty of Peace signed December 17, 1898, Cuba's status became that of a foreign Power in the military occupation of the United States, pending the establishment of an orderly Government. By the same treaty Spanish subjects were given twelve months in which to determine whether they were to retain or relinquish their allegiance to Spain. Until the end of that period it was impossible to know who might rightly participate in the work of reconstruction, and therefore the withdrawal of the United States and the establishment of a Cuban Government necessarily became a gradual process requiring much toil and firmness. The War Department issued a formal order in December 1898 making Cuba a military division, with Havana for headquarters. For the purposes of military administration the island was at first divided into military departments, each under a commanding officer carefully chosen from men with broad experiences in civil as well as military administration. The United States assumed entire control of Cuba January 1, 1899. President M'Kinley issued immediate proclamation defining government and organization and establishing custom rates. The supreme authority upon the island was vested in a Commanding-General, whose functions were very similar to those of the Captain-General under the Spanish régime. The first American Military Governor to be appointed upon the retirement of Spanish sovereignty was Major-General John R. Brooke, who entered upon his duties January 1, 1899. The Military Governor preserved and restored the Spanish forms of administration so far as they were compatible with good government. He established an advisory and administrative Cabinet composed of Secretaries, in whom were vested the administration of civil government. The departments and Ministers were known as those of state and government, finance, justice and public instruction, agriculture, commerce, industries, and public works. The military commanders there were instructed to restore local government as soon as possible. In carrying out this order the communal or municipal organization of the Spanish system was retained in spirit as well as form, and the people were permitted as far as possible to manage their local affairs. There are about two hundred municipalities in Cuba, and the alcaldes temporarily appointed were selected with great care.

The chief problems confronting the newly installed American authority were those of relief, police, sanitation, and reform of the judiciary. The last was especially needed. The civil and criminal code which was in existence prior to the relinquishment of Spanish sovereignty was retained in force, with such modifications and changes as might from time to time be found necessary in the interest of good government.

By decree of January 1, 1900, the department of Justice and Public Instruction was divided. The judiciary systems of the Spanish régime early received the attention of the American Military Governor, and was so modified as to result in more speedy attainment for the ends of justice, although retaining the forms of procedure and organization which previously existed. Upon the withdrawal of Spain, General Brooke organized a Supreme Court to hear cases and appeals, which under Spanish rule were sent to Spain for decision. This court, with its seat at Havana, was composed of a president, of a chief justice, six associate justices, one fiscal or prosecuting attorney, two assistant fiscals, one secretary, two deputy clerks, and other subordinate officials. Another court established was the Municipal or Correctional Court of Havana, the powers of which had hitherto been exercised by the mayors, and this system of police courts was afterwards applied to the whole island. A great obstacle to the administration of justice was the absence of remedial writs in the Spanish law of procedure. It was proposed, however, to institute the Habeas Corpus and other procedures for the protection of personal liberty as soon as expedient.

President M'Kinley, on August 17, 1899, ordered the taking of a census of the people of Cuba by disinterested citizens of Cuba as enumerators and supervisors. The proclamation of the President ordering the census was declared to be a preliminary step in the establishment of an effective system of self-government. The census was limited to inquiries concerning population, agriculture, and education as the three subjects of most importance. No previous census of Cuba as one had been taken since 1878. This work was accomplished with great thoroughness under the direction of Brigadier-General Sanger. The results of this census were beneficial in removing popular prejudices against the Cubans in the United States, demonstrating that a majority of the Cubans were of the white race and were generally more literate than the people of Spain and Porto Rico. The census also showed that the mortality due to the insurrection and the reconcentration had been less than had been ascribed. (For the details of the census results, see p. 303 above.)

*Census 1899.*

On January 1, 1900, Brigadier-General Leonard A. Wood succeeded General Brooke as Military Governor of the island. General Wood had shown great success as governor of the province of Santiago, and his appointment was considered eminently appropriate and satisfactory both to the Cubans and the Americans. One of the early acts of his administration was to show his trust in the Cuban people by giving them most of the executive offices. To him fell the difficult task of conducting the elections, and serving as an intermediary between the administration at Washington and the Cuban people. On July 25, 1900, the President directed that a call be issued for an election in Cuba for members of a constitutional Convention to frame a Constitution as a basis for a stable and independent Government in the island. In pursuance thereof Military-Governor Wood issued a proclamation again citing the fact that the United States disclaimed any disposition or intention to exercise sovereignty, jurisdiction, or control over the island except for the pacification thereof, and asserting its determination, when that was accomplished, to leave the government and control of the island to its people. Therefore he ordered a general election to be held on the third Saturday of September in the year 1900, to elect delegates to a Convention to meet in the city of Havana on the 1st Monday of November of the same year to frame and adopt a Constitution for the people of Cuba, and as a part thereof to provide for and agree with the Government of the United States upon the relations to exist between that Government and the Government of Cuba, and to provide for the election by the people of officers under such Constitution, and the transfer of government to the officers so elected. The election was held on the 15th of September, and the Convention assembled on the 5th of November 1900. Military-Governor Wood in opening the Convention said: "It will be your duty, first of all, to frame and adopt a Constitution for Cuba, and when that has been done, to formulate what in your opinion ought to be the relations between Cuba and the United States. The Constitution must be adequate to secure stable, orderly, and free government. When you have formulated the relations which, in your opinion, ought to exist between Cuba and the United States, the Government of the United States will doubtless take such action on its part as shall lead to final and authoritative agreement between the people of the two countries to the promotion of their common interests." The Convention expressed appreciation and gratitude to the United States Government and to General Wood for aid given to the Cuban people in advancing self-government.

*General Wood's appointment.*

By the end of January 1901 the Cuban Constitutional Convention had so far completed the instrument that its character and general features were evident. It was an able and well-written document, following in a general way the essential features of the Constitution of the United States. In one essential feature it was lacking, however—it did not mention the relations which were to exist between Cuba and the United States. In the Constitution as framed there "was no recognition of the United States, no expression of gratitude or even friendliness," and no provision was made for the relations to exist betwen Cuba and the United States, as stipulated in the call for the Convention. On March 2, 1901, Congress, appreciating the fact that the Cuban Constitution ignored the relations to exist between the future Cuban Republic and the United States, and in order to enable the President to withdraw the military forces from Cuba, through an amendment to the Military Appropriation Bill framed the articles known as the Platt Amendment. The Platt Amendment contained eight articles, specifically defining what the relations were to be between the future Cuban Republic and the United States. These articles, in essence, were as follow:—

*Cuban and American relations.*

1. Prohibiting Cuba from entering into treaties with foreign Powers tending to impair Cuban independence, or prohibiting them to obtain lodgment or control over any portion of the island.
2. Regulating Cuba's power to incur debts beyond the capacity of the island's ability to pay.
3. Providing that the United States shall have the right of intervention for the preservation of Cuban independence, the maintenance of an orderly Government, and for discharging the obligations of the United States relative to Cuba stipulated in the Treaty of Paris.
4. Ratification on validation of all acts of the United States while in temporary military occupation.
5. Requiring Cuba to execute and extend the plans for the sanitation of the island.
6. Demanding that the Isle of Pines be omitted from the constitutional boundaries of Cuba, and that its future status be fixed by treaty.
7. Demanding that Cuba sell or lease to the United States suitable sites for coaling or naval stations.
8. Demanding that the foregoing stipulations be embodied in the form of a permanent treaty.

The Radical element in Cuba bitterly advocated the rejection of any dictation from the United States. Finally it was determined in April 1901 that a Commission from the Cuban Constitutional Convention should visit Washington for the purpose of ascertaining the exact intent and meaning of the language of the Platt Amendment. This Commission consisted of Juan Gualberto Gomez, the Radical independent leader; Domingo Capote, the presiding officer of the Convention; Dr Berriel, a noted constitutional lawyer; Judge Florente, an associate justice of the Cuban Supreme Court; Rafael Portuondo, an extreme Radical; Diego Tamayo, and a Nationalist and member of Governor Wood's cabinet. The Cuban Commission reached Washington April 24, 1901, and was given every attention and consideration. After many interviews with the President and Secretary of War, the members were informed that the United States would insist upon its position. President Capote, of the Commission, asked the President to do something for the Cubans upon an economic line, especially in the matter of reciprocal trade relations. He said that it was especially desirable that something of this kind be done before the next crop was harvested, in order that the Cubans might thus realize the advantages of closer political and economic relations with the United States. To this inquiry the reply was made that Congress alone had the power to regulate commerce. It was supposed after the visit of the Commission to Washington that the

Constitutional Convention would appreciate that the United States had no ulterior motives in attempting to establish and protect the Cubans in an independent Government. Upon the return of the Commission the Convention decided to accept the Platt Amendment, and the incident was supposed to be closed. It was subsequently ascertained, however, that the acceptance was accompanied by a Cuban interpretation, whereupon (June 1901) the President issued his dictum that until the Cuban Convention accepted the Platt Amendment in its entirety, the troops of the United States would be retained upon the island. On June 18th, 1901, the Convention, seeing that further dallying was useless, accepted the amendment in its entirety, and a Cuban Republic was inaugurated on May 20, 1902, with Senor Palma as first president.

*Results of American action.*

It is impossible to set forth here what the Americans have done for the social and industrial improvement of the island. Brigandage and mendicity were eliminated. The establishment of a thorough public school system was accomplished, superintendents and teachers being imported. As a result, 150,000 Cuban children were obtaining free education in 1900, while only 27,000 children had hitherto found instruction. In 1900, 1400 Cuban teachers were given free transportation to, and instruction at, Harvard University. Cuban prisons were in bad sanitary condition, and the time of detention was long. In Havana twenty-two Americans were found imprisoned over five months with no hearing. Over 1500 people were found in the jails in Cuba who had never been tried. The sanitary cleansing of the cities was undertaken on a gigantic scale. The sanitation of Havana—a plague-spot which had long menaced the United States—was thoroughly studied and the city changed into one of the cleanest in the world. Colonel Geo. E. Waring, America's ablest sanitary engineer, personally studied the sanitary conditions of Cuba, and died of yellow fever contracted in this work. Not only were matters of public hygiene carefully attended to, but the Surgeon-General of the army established in Havana a corps of medical investigators, who attacked the problem of the causes and dissemination of yellow fever with great energy. In the summer of 1901 they demonstrated by experimentation that the cause of the dissemination of the disease was the mosquito. The death-rate of Havana decreased nearly one-half as a result of the sanitary measures which were taken, and yellow fever, for the first time in the history of Havana, was not epidemic in 1901. It had already become apparent that the army surgeons, through their sanitation and researches, had obliterated the conditions which once made Havana the focus and distributing centre of this disease in the New World. Postal and telegraphic communication was greatly improved and placed upon a systematic basis. The peculations of a few postal authorities, who were duly arrested and punished, was the only blot upon the American administration. The rehabilitation of the fields and plantations has been encouraged. Seeds and animals were at first furnished, but by 1901 all agricultural industries were self-sustaining, and the sugar and tobacco industries had recovered the full development which they possessed before the insurrection in 1895. In 1901 Cuba might be described as better off socially and economically than at any period since 1840. From a political standpoint the acts of the United States have been even more munificent. The United States spent millions of money and many lives in a war with Spain for the sake of Cuba; sent aid to its starving population; paid three million dollars to the insurgent soldiers; and assumed payment of all damages which American citizens sustained during the revolution. (R. T. H.)

**Cuddalore,** a town of British India, in the South Arcot district of Madras; on the seacoast, 125 miles south of Madras. In 1881 it had a population of 43,545; in 1891, of 47,355; and in 1901, of 51,880, showing an increase of 10 per cent. The municipal income in 1897–98 was Rs.51,710. The mouth of the river Gaddilam having silted up, the anchorage is an open roadstead. In 1897–98 the total seaborne trade amounted to Rs.61,46,419, of which nearly half was with foreign countries. The principal exports are sugar, oil-seeds, and indigo. There are two colleges, two high schools with 861 pupils, two printing-presses, and a club.

**Cuddapah,** a town and district of British India, in the Madras Presidency. The town is 6 miles from the right bank of the river Pennar, and 161 miles by rail from Madras. Population, about 18,000. The municipal income in 1897–98 was Rs.47,830. It is now a poor place, but has some trade in cotton and indigo, and manufactures of cotton cloth. There are a high school, two printing-presses, and a literary association.

The DISTRICT OF CUDDAPAH has an area of 8722 square miles. Population (1891), 1,272,072; (1901), 1,291,903. The land revenue and rates were Rs.22,51,654, the incidence of assessment being R.1·8 per acre; the number of police was 1002. In 1897–98, out of a total cultivated area of 1,586,665 acres, 282,702 were irrigated. The principal crops are millet, rice, other food-grains, pulse, oil-seeds, cotton, and indigo. The two last are largely exported. There are two steam factories for pressing cotton; and 570 indigo vats, employing 8417 persons, with an out-turn valued at Rs.6,37,000. In 1896–97 the number of schools was 846, attended by 18,652 pupils. The registered death-rate in 1897 was 25·9 per thousand. The district is served by two lines of railway.

**Cuenca,** a province of Central Spain, with a population of 236,253 in 1877, 242,024 in 1887, and 241,566 in 1897. In 1896, of 47,764 children of both sexes, ranging from 4 to 14 years of age, 28,146 were on the school registers, though only 19,779 attended. The province is divided into 8 administrative districts and 288 parishes, covering an area of 6726 square miles. It is the least thickly peopled province in Spain, and has only 68 miles of railway, but a new line is under construction. The roads are in such a backward condition that they cripple not only the mining interests but also the exports of timber, which is generally floated down the Tagus and other streams. There are but few manufacturing interests. In 1897 the province contained 3 salt mines in working order. An English company bought the principal copper mines near Garabella and Talayuelim in 1898. The province, chiefly owing to its hilly pasture grounds, had a goodly show of live-stock in 1897—291,205 sheep, 51,266 goats, 20,191 pigs, 3232 horses, 25,503 mules, 21,315 asses, 4149 cattle. 225,600 acres were devoted to the culture of wheat, 48,402 to that of barley, 39,157 to rye, 16,250 to oats, 62,207 to vines, 30,320 to olives. CUENCA, the capital, has much decayed in importance. The wool trade has been in part replaced by manufactures of soap, paper, chocolate, matches, and leather. There are many saw mills, worked by steam. The population has grown from 9745 in 1887 to 10,332 in 1897. Cuenca attracted notice by its gallant and prolonged resistance against the Carlists in 1874.

**Cuenca,** a town of Ecuador, and capital of the province of Azuay, about 80 miles south-east of Guayaquil. It is the second town of the interior in importance, and the third in rank of the republic. Population, about 25,000.

**Cuesmes,** a town of Belgium, in the province of Hainaut, 2 miles south-west of Mons, with which it is united by rail. It has a coal-mining industry and railway workshops. Population (1880), 7079; (1897), 8626.

**Cuevas de Vera,** a town of Spain in the province of Almeria, near the Mediterranean, in a plain fringed by the river Almanzora. Population (1897), 20,366. It has two fine squares, de la Constitucion and del Castillo, the latter deriving its name from the residence of the Marquesses of Villafranca, one of whose towers is said to be a Roman structure. The parish church, La Encarnacion, dates from 1758 and is of Doric style. The town is essentially a mart for the products of mines in the Sierra Almaguera, and for the products of the rich agricultural districts around.

**Cullera,** a seaport of Spain, in the province of Valencia, 24 miles south-south-east of Valencia, on the Mediterranean at the mouth of the Jucar. In 1898 the principal imports were sulphate of ammonia, valued at £23,070, and artificial manure, valued at £2600. The return of shipping in 1898 showed that 42 vessels entered with 24,199 tons of cargoes, and 27 in ballast with 8490 tons; 7 English vessels with 4173 tons entered. Twenty-seven Spanish vessels cleared with 8490 tons of cargoes, and 42 vessels in ballast with 24,199 tons cleared, 7 being English.

**Cumberland,** a north-western county of England on the Scottish border, bounded on the S.W. and W. by the Irish Sea, on the N.W. by the Solway Firth, Dumfries, and Roxburgh, on the N.E. by Northumberland, on the E. by Durham, and on the S.E. by Westmoreland and Lancashire.

*Area and Population.*—The area of the ancient, administrative, and registration county is given in the census returns as 970,161 acres or 1516 square miles, with a population in 1881 of 250,647, in 1891 of 266,549 (of whom 132,100 were males and 134,449 females, the number of persons per square mile being 176, and of acres to a person 3·64), and in 1901 of 266,921. The urban population (1891) numbered 150,168, and the rural 116,381. Between 1881 and 1891 the percentage of increase was 6·34. The excess of births over deaths between 1881 and 1891 was 38,597, but the actual increase of resident population was only 15,902. The following table gives the number of marriages, births, and deaths, with the number of illegitimate births for 1880, 1890, and 1898:—

| Year. | Marriages. | Births. | Deaths. | Illegitimate Births. | |
|---|---|---|---|---|---|
| | | | | Males. | Females. |
| 1880 | 1721 | 8504 | 5153 | 347 | 343 |
| 1890 | 1941 | 8441 | 4928 | 342 | 396 |
| 1898 | 2017 | 7543 | 4680 | 281 | 228 |

In 1899 the number of marriages was 1978, of births 7660, and of deaths 4307.

The following table gives the marriage-, birth-, and death-rates per 1000 persons living, with the percentage of illegitimate births for a series of years:—

| | 1870-79. | 1880. | 1880-89. | 1890. | 1888-97. | 1898. |
|---|---|---|---|---|---|---|
| Marriage-rate | 15·5 | 13·8 | 13·8 | 14·6 | 13·4 | 14·5 |
| Birth-rate | 35·1 | 34·2 | 33·6 | 31·8 | 30·2 | 27·2 |
| Death-rate | 21·6 | 20·7 | 19·5 | 19·0 | 17·2 | 16·9 |
| Percentage of illegitimacy | 8·9 | 8·1 | 7·6 | 7·6 | 7·2 | 6·7 |

In 1891 there were in the county 11,826 natives of Scotland, 9628 natives of Ireland, and 404 foreigners.

*Constitution and Government.*—The county is divided into four parliamentary divisions, and it also includes the parliamentary boroughs of Carlisle and Whitehaven. It contains three municipal boroughs—Carlisle (39,176), Whitehaven (18,879), and Workington (23,490). The following are urban districts:—Arlecdon and Frizington (5697), Aspatria (2714), Cleator Moor (9464), Cockermouth (5464), Egremont (6258), Harrington (3535), Holme Cultram (4602), Keswick (4500), Maryport (12,536), Millom (8895), Penrith (8981), and Wigton (3965). The county is in the northern circuit, and assizes are held at Carlisle. The borough of Carlisle has a separate court of quarter sessions and separate commissions of the peace. The ancient county constitutes part of the archdeaconry and diocese of Carlisle, and contains 162 entire ecclesiastical parishes.

*Education.*—At Carlisle is a school of science and art. At St Bees there is an ancient grammar school. The Theological College of St Bees was closed in 1897. The number of elementary schools on 31st August 1899 was 286, of which 105 were board and 181 voluntary schools, the latter including 153 National Church of England schools, 1 Wesleyan, 14 Roman Catholic, and 13 "British and other." The average attendance at board schools was 22,635, and at voluntary schools 22,339. The total school board receipts for the year ending 29th September 1899 were over £85,695. The income under the Agricultural Rates Act was over £32,645.

*Agriculture.*—The county being mountainous, the acreage under cultivation is much below the average—only about three-fifths of the whole; while nearly three-fifths of this acreage is in permanent pasturage. In addition, over 261,000 acres are in hill pasture and over 35,000 acres under woods. Sheep are largely kept and many cattle are reared. Of the corn crops about nine-tenths are under oats, while about three-fourths of the green crop area is occupied by turnips and swedes. The following table gives particulars at intervals of five years from 1880:—

| Year. | Total Area under Cultivation. | Corn Crops. | Green Crops. | Clover. | Permanent Pasture. | Fallow. |
|---|---|---|---|---|---|---|
| 1880 | 574,665 | 94,422 | 47,291 | 105,182 | 322,780 | 4989 |
| 1885 | 579,069 | 92,923 | 46,598 | 107,270 | 329,237 | 3039 |
| 1890 | 593,991 | 89,973 | 47,391 | 114,805 | 339,510 | 2129 |
| 1895 | 579,404 | 85,880 | 46,200 | 115,654 | 330,105 | 1211 |
| 1900 | 582,036 | 78,728 | 42,515 | 115,532 | 344,428 | 561 |

The following table gives the numbers of the principal live-stock for the same years:—

| Year. | Total Horses. | Total Cattle. | Cows or Heifers in Milk or in Calf. | Sheep. | Pigs |
|---|---|---|---|---|---|
| 1880 | 20,654 | 132,032 | 41,429 | 517,410 | 20,574 |
| 1885 | 20,288 | 139,329 | 45,579 | 494,553 | 24,104 |
| 1890 | 20,442 | 138,086 | 46,393 | 562,252 | 31,717 |
| 1895 | 22,542 | 141,937 | 45,941 | 518,276 | 23,708 |
| 1900 | 21,557 | 148,339 | 48,145 | 580,618 | 18,816 |

*Industries and Trade.*—According to the report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 19,371 as compared with 19,598 in 1896. Of these 2212 were employed in textile factories. Non-textile factories employed 14,958 persons, there being between 1895 and 1896 an increase of 15·5 per cent; but between 1896 and 1897 a decrease of 2·5 per cent. Of these 4088 were employed in the founding and conversion, and 2087 in the extraction, of metals, the other principal industries being the manufacture of machines, appliances, conveyances, tools, &c., employing 2135 persons, and food employing 1642. There is some iron shipbuilding. Of the 2201 persons employed in workshops, 1625 were employed in clothing industries. The total number of persons employed in mines and quarries in 1899 was 14,560. Within recent years the mining industries of the county have made rapid progress. Of granite 103,923 tons were raised in 1899, of limestone 524,417 tons, of clays 75,427 tons, and of sandstone 52,352 tons. There is a large production of pig iron, 687,874 tons in 1885, 832,614 tons in 1890, 648,740 tons in 1895 and 954,637 tons in 1899. The seats of the industry are Whitehaven, Workington, Cleator Moor, Maryport, and Millom. The following table gives particulars regarding the output of the more important minerals in 1890 and 1899:—

| Year. | Coal. | | Gypsum. | | Iron Ore. | | Lead. | | Zinc. | |
|---|---|---|---|---|---|---|---|---|---|---|
| | Tons. | Value. | Tons. | Value | Tons. | Value. | Tons | Value | Tons | Value. |
| | | £ | | £ | | £ | | £ | | £ |
| 1890 | 1,740,113 | 658,0[illegible] | 20,851 | 5213 | 1,480,159 | 804,474 | 2272 | 18,005 | 4809 | 15,569 |
| 1899 | 2,100,118 | 710,9[illegible] | [illegible],858 | 8772 | 1,137,750 | 833,879 | 825 | 7,691 | 714 | 36,9[illegible] |

On account of the number of lakes, rivers, and streams, the fresh-water fisheries are of considerable importance, and include besides trout and salmon, char, pike, perch, lamprey, and eels. At Whitehaven, Maryport, and Morecambe the amount of fish landed in 1899 was 7766 cwt., valued at £14,241.

**Cumberland,** capital of Alleghany county, Maryland, U.S.A., situated in the mountainous western portion of the state, at an altitude of 626 feet, on the main western line of the Baltimore and Ohio Railway, and on four other lines. It is on the border of the Cumberland coal-field, and through these railways, and the Chesapeake and Ohio Canal, of which it is the western terminus, it has a large trade in coal. It has rolling-mills, and other iron and steel works, glass and railway works. Population (1880), 10,693; (1900), 17,128.

**Cumberland,** a town of Providence county, Rhode Island, U.S.A., with an area of 27·5 square miles of hilly country. It is bordered on the west by Blackstone river, on which are several small villages, the remainder of the population being rural. Population (1880), 6445; (1900), 8925.

**Cumberland River,** a large southern branch of Ohio river, U.S.A., rising in the highest portion of the Cumberland plateau, in eastern Kentucky. From its source it flows westwards, then south into Tennessee, thence again westwards, passing Nashville, and finally north-westwards across the western part of Kentucky, to its mouth at Smithfield, a few miles above the mouth of Tennessee river. Its entire length is about 700 miles, of which much the greater part is navigable. Its drainage basin comprises 18,573 square miles. During the Civil War Fort Donelson was erected on the Cumberland and Fort Henry on the Tennessee by the Confederates, about 40 miles above their mouths, to prevent navigation by Federal vessels. These forts were captured by General Grant in February 1862, with 14,000 prisoners, and the rivers were thus opened up to Federal gunboats.

**Cumnock,** a police burgh of Ayrshire, Scotland, 33¾ miles south of Glasgow by road. There is a town-hall, an athenæum, a public library, and a monument to "Prophet" Peden, the Covenanter. Coal and ironstone are extensively mined in the neighbourhood, and there are several woollen and tweed mills in the town. The churches are Established, United Free, Congregational Union, Baptist, and Roman Catholic. The public school had an average attendance of 522 in 1898–99, and a Roman Catholic school 102. Population (1881), 3345; (1901), 3087.

**Cundinamarca,** a department of the republic of Colombia, bounded on the N. by Venezuela and the departments of Boyacá and Santander, on the W. by Antioquia and Tolima, on the S. by Cauca, and on the E. by Venezuela. Area, 79,691 square miles. Population, 500,000, of whom one-fourth are whites, the rest Indians and half-breeds. The capital, Bogotá, which is also the capital of the republic, has about 100,000 inhabitants. Principal towns: Zipaquirá, Facatativá, Cáqueza, Fómeque, Choconta.

**Cuneo,** a town, episcopal see, and capital of the province of Cuneo, Piedmont, Italy, 54 miles by rail south-south-west from Turin, on a rocky platform above a tributary of the Tanaro, at the northern foot of the Maritime Alps. Apart from the broad arcaded main street, the streets are narrow and crooked. The chief buildings are the (restored) cathedral, the 12th-century Franciscan church, the town-hall, theatre, and military hospital. The former town walls have been converted into promenades. A monument to Barbaroux was erected in 1879. Silk-spinning, raising of cocoons, and printing are the principal industries. There is a school of the industrial arts and handicrafts. Population of town, about 17,000; of commune, about 29,000.

**Cupar Fife,** a royal, parliamentary (St Andrews group), and police burgh, and the county town of Fifeshire, Scotland, on the river Eden, 45 miles north of Edinburgh by the Forth Bridge and 16 south-west of Dundee by rail. The business of the town chiefly depends on its importance as an agricultural and legal centre. A handsome new Free church was erected in 1877–78. The Madras Academy having received a supplementary endowment from a legacy of Sir David Baxter is now known as the Bell-Baxter school, and is one of the five recognized higher-class schools of the county. The county buildings were enlarged in 1892–93. Population of the parliamentary and police burgh (1881), 5010; (1891), 4729; (1901), 4511; and of the royal burgh (1881), 4964; (1891), 4693.

**Curaçoa** or **Curaçao,** an island in the Caribbean Sea off Venezuela, and the name of a government comprising that island and its dependencies, the other Dutch West Indies—Oruba (Aruba) and Buen Aire (Bonaire), near the coast of Venezuela; Saba, St Eustatius, and the half of St Martin, in the Lesser Antilles. Total area, 530 square miles. The islands near the coast of South America consist of slate, cretaceous formations, and eruptive rocks (diorite and diabase), forming ridges 650 to 1300 feet high, and plateaux or hills 200 to 500 feet. The islands of the Lesser Antilles are of volcanic (Saba, St Eustatius) or Tertiary (St Martin) rocks. The principal occupations are the rearing of cattle, the cultivation of fruit trees (palms), aloe, and divi-divi, and the working of salt and phosphate. The island of Curaçoa is the only one with a good port, Willemstad (population about 8000), with a total traffic valued at £160,240 in 1899, while that for the rest of the islands amounted only to £21,300. The total population in 1898 was 51,693, of whom only 425 were born in the Netherlands. (Curaçoa, 30,119; Bonaire, 4926; Aruba, 9591; St Martin (Dutch part), 3485; St Eustatius, 1383; Saba, 2189.)

Genootschap* (1883–86).

**Curci, Carlo Maria** (1809–1891), Italian theologian, was born at Naples on the 4th of September 1809. He became a novice of the Order of Jesuits in 1826, and was ordained priest in 1837. For some years he was stationed at the Church of the Gesù at Naples, was made rector of the schools, and also devoted himself to work among the poor and in the prisons. Here he came into close relations with Gioberti, Rosmini, and other advocates for reform in the Italian Church. Curci wrote a preface to Gioberti's *Primato*, published in 1843, but he protested against Gioberti's *Prolegomena*, and wrote against his later books in favour of reform. After the fall of the Papal Government in 1870 Curci delivered discourses on Christian Philosophy at Florence. In 1874 he published

an Introduction to his Exegetical Lessons on the Gospels. In 1879 and 1880 appeared his edition of the New Testament, in the preface to which he made some severe remarks on the neglect of the study of the Scriptures among the Italian clergy. In the meantime he had commenced the campaign against the Vatican which has made him famous. In his *Il Moderno Dissidio tra la Chiesa e l'Italia* (1878) he advocated an understanding between Church and State. In his *La Nuova Italia ed i Vecchi Zelanti* (1881) he inveighed against the condition of the Vatican at that period. In 1883 he published his *Vaticano Regio*, in which he accuses the Church of making merchandise of the holiest things, and declares that her worldliness was due to the false principles she had embraced. He still kept up his sympathy with the working class, and expressed it in a striking treatise on Christian Socialism, in which he invoked State interference to check the inequality with which profits were shared between employer and employed. Excommunicated and deprived, he was reduced to beggary, and in 1884 he retracted "all that he had said contrary to the faith, morals, and discipline of the Church." He passed the remainder of his life in retirement, and died at Villa Careggi, near Florence, on 8th June 1891. (J. J. L*.)

**Curico,** a city of Chile, capital of the province and department of the same name, 114 miles from Santiago by rail, situated in 34° 58′ S. lat. and 71° 19′ W. long. Population, 15,000.

**Curitiba,** a city of Brazil, and capital of the state of Paraná. The population is 20,000, of whom over 12,000 are foreign-born (4000 Germans, 4000 Italians, 2000 Poles, and from 2000 to 3000 Portuguese, Spaniards, &c.). Nearly all the wholesale trade is in the hands of Germans. In the vicinity of Curitiba are prosperous colonies of Italians, Germans, Poles, &c.

**Curling, Thomas Blizard** (1811–1888), British surgeon, was born in London in 1811. Through his uncle, Sir William Blizard, he became assistant-surgeon to London Hospital in 1833, becoming full surgeon in 1849. After filling other important posts in the College of Surgeons, he was appointed President in 1873. In 1843 he won the Jacksonian prize for his investigations on tetanus; and he became famous for his skill in treating diseases of the testes and rectum, his published works on which went through many editions. He died on 4th March 1888.

**Curtea d'Argesh,** a town in Rumania, on the southern slopes of the Carpathians (population in 1900, 4210), north-west of Pitesti, connected by railway with Bucharest. It derives its name from Courtea (the Court), having been the residence of Radu Negru early in the 13th century. It contains two interesting churches, one of which was constructed by Radu himself. About 1½ miles north of the town is the cathedral, a magnificent and unique specimen of Byzantine art. There are myths connected with its foundation, which have been put into beautiful and pathetic verse by the Rumanian poet, B. Alexandri, but as a matter of fact it was constructed by the Prince Nagul Bassaraba, who governed Wallachia from 1512 to 1522, and who studied architecture while a hostage at Constantinople at the court of the Sultan Selim. Aided by another architect, Manoli, he erected this cathedral, which was completely reconstructed with great taste and success at the expense of the Rumanian Government between 1875 and 1885, under the direction of a French architect, M. Lecomte de Nouy. It was reconsecrated with great pomp in the presence of the king on 12th October 1886.

**Curtis, George Ticknor** (1812–1894), American legal writer and constitutional historian, was born in Watertown, Massachusetts, 28th November 1812. He graduated at Harvard University in 1832, became a lawyer, and practised his profession in Boston, New York, and Washington. He was the nephew and close friend of George Ticknor, the historian of Spanish literature, and his association with his uncle was influential in developing his scholarly tastes; while his other personal friendships with eminent Bostonians during the period of conservative Whig ascendancy in Massachusetts politics were of direct influence upon his political opinions and published estimates. After preparing a number of law-books, one of which—on the *Rights and Duties of Merchant Seamen*—elicited the hearty praise of Mr Justice Story, he issued in 1855–58 the first of the two works upon which his place in literature depends: *A History of the Origin, Formation, and Adoption of the Constitution of the United States, with Notices of its principal Framers.* This history, which had been watched in its earlier progress by Daniel Webster, may be said to present the old federalist or "Webster–Whig" view of the formation and powers of the constitution; and it was natural that Mr Curtis should follow it with a voluminous *Life of Daniel Webster* (2 vols., 1870). Both these works were characterized by solidity and comprehensiveness rather than by rhetorical attractiveness or literary perspective. In his later years Mr Curtis, like so many of the followers of Webster, turned towards the Democratic party; and he wrote, among other works of minor importance, an exculpatory life of President James Buchanan (2 vols., 1883) and two vindications of General George B. M'Clellan's career (1886 and 1887). He died in New York, 28th March 1894.

**Curtis, George William** (1824–1892), American man of letters, was born in Providence, R.I., 24th February 1824. He came of old New England stock, and at the time of his birth the New England community was at its best. His mother died when he was two years old. At six he was sent with his elder brother to school in Jamaica Plain, Mass., where he remained for five years. Then, his father having again married happily, the boys were brought home to Providence, where they stayed till, in 1839, their father removed to New York. Three years later, Curtis, being allowed to determine for himself his course of life, and being in sympathy with the spirit of the so-called Transcendental movement, became a boarder at the community of Brook Farm. He was accompanied by his brother, whose influence upon him was strong and helpful. He remained there for two years, brought into stimulating and serviceable relations with many interesting men and women. Then came two years, passed partly in New York, partly in Concord, in order mainly to be in the friendly neighbourhood of Emerson, and then followed four years spent in Europe, Egypt, and Syria. Curtis returned from Europe in 1850, handsome, attractive, accomplished, ambitious of literary distinction. He instantly plunged into the whirl of life in New York, obtained a place on the staff of the *Tribune*, entered the field as a popular lecturer, set himself to work on a volume published in the spring of 1851, under the title of *Nile Notes of a Howadji*, and became a favourite in society. He wrote much for *Putnam's Magazine*, of which he was associate editor; and a number of volumes, composed of essays written for that journal and for *Harper's Monthly*, came in rapid succession from his pen. The chief of these were the *Potiphar Papers*, a satire on the fashionable society of the day; and *Prue and I*, a pleasantly sentimental, fancifully tender and humorous study of life. In 1855 he married Miss

Anna Shaw. Not long after his marriage he became, through no fault of his own, deeply involved in debt owing to the failure of *Putnam's Magazine*; and his high sense of honour compelled him to devote the greater part of his earnings for many years to the discharge of obligations for which he had become only by accident responsible, and from which he might have freed himself by legal process. In the period just preceding the Civil War other interests became subordinate to those of national concern. Curtis made his first important speech on the questions of the day at Wesleyan University in 1856; he engaged actively in the Presidential campaign of that year, and was soon recognized not only as an effective public speaker, but also as one of the ablest, most high-minded, and most trustworthy leaders of public opinion. In 1863 he became the political editor of *Harper's Weekly*, and no other journal exercised during the war and after it a more important part in shaping public opinion. His writing was always clear, direct, forcible; his fairness of mind and sweetness of temper were invincible. He never became a mere partisan, and never failed to apply the test of moral principle to political measures. From month to month he contributed to *Harper's Monthly*, under the title of "The Easy Chair," brief essays on topics of social and literary interest, charming in style, touched with delicate humour, and instinct with generous spirit. His service to the Republican party was such, that more than once he was offered nominations to office of high distinction, and might have been sent as Minister to England; but he refused all offers of the kind, feeling that he could render more essential service to the country as editor and public speaker. In 1871 he was appointed by President Grant chairman of the Commission to report on the reform of the Civil Service. The report which he wrote was the foundation of every effort since made for the purification and regulation of the Service and for the destruction of political patronage. From that time till his death Mr Curtis was the leader in this reform, and to his sound judgment, his vigorous presentation of the evils of the corrupt prevailing system, and his untiring efforts, the progress of the reform is mainly due. He was the President of the National Civil Service Reform League and of the New York Civil Service Reform Association. In 1884 he refused to support the nomination of Mr Blaine as candidate for the Presidency, and thus broke with the Republican party, of which he had been one of the founders and leaders. From that time he stood as the typical independent in politics. In April 1892 he delivered at Baltimore his eleventh annual address as President of the National Civil Service Reform League, and in May he appeared for the last time in public, to repeat in New York an admirable address on James Russell Lowell, which he had first delivered in Brooklyn on the 22nd of the preceding February, the anniversary of Lowell's birth. On the 31st of the following August he died. He was a man of consistent virtue, whose face and figure corresponded with the traits and stature of his soul. The grace and charm of his manner were the expression of his nature. Of the Americans of his time few were more widely beloved, and the respect in which he was held was universal.

See:—*George William Curtis*, by EDWARD CARY, in the series of Lives of American Men of Letters (Boston, 1894); an excellent biography.—"An Epistle to George William Curtis," by JAMES RUSSELL LOWELL, 1874–87. In Lowell's *Poems*. — *George William Curtis*, a Commemorative Address delivered before The Century Association, 17th December 1892, by PARKE GODWIN. New York, 1893.—*Orations and Addresses by George William Curtis*, edited by CHARLES ELIOT NORTON, 3 vols., 8vo. New York, 1894.

(C. E. N.)

**Curtius, Ernst** (1814–1896), German archæologist and historian, was born at Lübeck on 2nd September 1814. On completing his university studies he was chosen by Professor Brandis to accompany him on a journey to Greece for the prosecution of archæological researches. Curtius then became Otfried Müller's companion in his exploration of the Peloponnesus, and on Müller's death in 1840 returned to Germany. In 1844 he became an extraordinary professor at the University of Berlin, and in the same year was appointed tutor to Prince Frederick William (afterwards Emperor Frederick III.)—a post which he held till 1850. After holding a professorship at Göttingen and undertaking a further journey to Greece in 1862, Curtius was appointed in 1863 ordinary professor at Berlin. At the same time he became Secretary of the Royal Academy of Science, of which he had been a member since 1853. In 1874 he was sent to Athens by the German Government, and concluded an agreement by which the excavations at Olympia were entrusted exclusively to Germany. Among the results of these excavations was the discovery of Praxiteles' famous statue of Hermes. He died at Berlin on 11th July 1896. Curtius' best-known work is his *History of Greece* (1857–67; English translation by A. W. Ward, 1868–73). It presented to the public in an attractive style the latest results of scholarly research, but was criticized as wanting in erudition. His other writings are chiefly archæological. The most important are: *Die Akropolis von Athen* (1844); *Naxos* (1846); *Peloponnesos, eine historisch geographische Beschreibung der Halbinsel* (1851); *Olympia* (1852); *Die Ionier vor der ionischen Wanderung* (1855); *Attische Studien* (1862–65); *Göttinger Festreden* (1864); *Sieben Karten zur Topographie von Athen nebst einem erläuternden Text* (1868); *Ephesos* (1874); *Die Ausgrabungen zu Olympia* (1877, etc.); *Olympia und Umgegend* (edited by Curtius and Friedrich Adler, 1882); *Olympia, Die Ergebnisse der von dem Deutschen Regierung veranstalteten Ausgrabung* (also with F. Adler, 1890–98); *Die Stadtgeschichte von Athen* (1891). His collected speeches and lectures were published in 2 vols. under the title of *Altertum und Gegenwart* (1875 and 1882), to which a third volume was added under the title of *Unter drei Kaisern* (1889).

His brother, GEORG (1820–1885), philologist, was born at Lubeck on 16th April 1820. After an education at Bonn and Berlin he was for three years a schoolmaster in Dresden, until (in 1845) he returned to Berlin University as *privat-docent*. In 1849 he was placed in charge of the Philological Seminary at Prague, and two years later was appointed Professor of Classical Philology in Prague University. In 1854 he removed from Prague to a similar appointment at Kiel, and again in 1862 from Kiel to Leipzig. His philological theories had a widespread influence upon the study of that science. The more important of his publications are: *Sprachvergleichung in ihrem Verhältniss zur classischen Philologie* (1845), *Sprachvergleichende Beiträge zur griechischen und lateinischen Grammatik* (1846), *Grundzüge der griechischen Etymologie* (1858–62), *Das Verbum der griechischen Sprache* (1873). From 1868 to 1878 he was general editor of *Studien zur griechischen und lateinischen Grammatik*, and, from 1878 till his death, of a similar publication entitled *Leipziger Studien zur classischen Philologie*. His Greek Grammar for Schools, first published in 1855, passed through a number of editions, and has been edited in English. He died at Hermsdorf on 12th August 1885.

**Curzola,** chief town of the Adriatic island of the same name in the Austrian province of Dalmatia. The

principal resources of the population are boat-building, fishing, and seafaring, the cultivation of the vine, corn, and oil, and breeding of mules. Population of island, 18,749; of town, 6486.

**Cushing, Caleb** (1800–1879), American statesman, was born in Salisbury, Mass., on the 17th of January 1800. He was graduated from Harvard in 1817, and began the practice of law in Newburyport. After serving in each house of the State legislature he was a Representative in Congress from 1835 to 1843. Originally a Whig, he supported President Tyler, and gradually became associated with the Democrats. As Commissioner to China he negotiated the first treaty between that country and the United States. He raised a regiment for the Mexican War, and rose to the rank of brigadier-general. During the administration of President Pierce he was Attorney-General of the United States. In 1860 he associated himself with the Breckinridge wing of the Democratic party. In 1866 he was appointed one of the three commissioners to revise and codify the laws of Congress. In 1868 he was sent on a diplomatic mission to Bogotà. At the Geneva Conference for the settlement of the *Alabama* claims he was one of the counsel for the United States. In 1873 he was nominated Chief Justice of the United States, but the nomination was not confirmed. From 1874 to 1877 he was United States minister to Spain. He died at Newburyport, Mass., on the 2nd of January 1879.

**Cushman, Charlotte Saunders** (1816–1876), the famous American actress, was born of New England stock in Boston, Mass., 23rd of July 1816. She went on the opera stage in 1834 in consequence of her father's financial failure and death, successfully appearing as the Countess Almaviva in *The Marriage of Figaro.* Her voice failing for purposes of singing, she took to the dramatic stage, playing Lady Macbeth (1835) with distinction. Convinced that she had not served a proper apprenticeship, she engaged herself as a stock actress, but was soon given the leading parts, among them high comedy impersonations. In 1844 she accompanied Macready on an American tour, winning great reputation in a series of tragedy parts. In 1844 and in 1853 she played successful engagements in London. She was a keen student, and acquired a large range of classic *rôles.* Her best parts were perhaps Lady Macbeth and Queen Catherine, her most popular being Meg Merrilies. Her figure was commanding and her face expressive, and she was animated by a temperament full of vigour and fire. These qualities enabled her to play with success such male parts as Romeo and Cardinal Wolsey. She died at Boston on the 18th February 1876.

See also *Charlotte Cushman, her Letters and Memories of her Life.* Edited by Emma Stebbins. Boston, 1878.

**Cusset,** a town in the arrondissement of Lapalisse, department of Allier, France, 31 miles south by east of Moulins, with station (2 miles distant) on railway to Vichy. It is situated at the confluence of the Sichon and Jolan, two small affluents of the Allier, and 2 miles north-east of Vichy, with which it is connected by a beautiful avenue. Its mineral waters are renowned, and its industries include paper, linen, oil, and basket-work. The town grew up around a convent founded in 886, and afterwards, in the 13th century, converted into an abbey of St Benoit. Louis XI. improved and fortified the town. A relic of that period is the Grosse Tour, now used as a prison. The fortifications have been replaced by boulevards, but many of the older houses exhibit the architectural features of the 15th and 16th centuries. Population (1881), 4955; (1901), 6444.

**Custer, George Armstrong** (1839–1876), American soldier, was born in New Rumley, Ohio, on 5th December 1839. After graduating at the U.S. Military Academy in June 1861, he entered at once the Union service early in the Civil War. As a young cavalry officer he impressed General M'Clellan, who in May 1862 appointed him an aide-de-camp with the rank of captain. Under General Pleasanton and General Sheridan he subsequently rose rapidly, both in volunteer and regular rank, while the Virginia operations lasted. He participated in all but one of the battles of the Army of the Potomac, led the cavalry division in pursuit of Lee's army, 1865, received its first flag of truce, and was present at the surrender at Appomattox Court House. At the age of twenty-five he was major-general of volunteers. After the war he engaged in service on the Western frontier. In an expedition against the Indians he and his entire command were massacred, after a desperate struggle, on 25th June 1876, by an overwhelming hostile force. Both Custer and his wife wrote interesting books descriptive of Indian frontier life.

**Cüstrin,** a town of Prussia, at the confluence of the Oder and the Warthe, 18 miles north by east of Frankfurt; three railway stations. It has three Protestant churches, a Catholic church, a gymnasium, a higher grade and a burgher school, a school for mechanics, four machinery works, and other manufactures. Population (1890), 16,672; (1900), 16,463.

**Cutch** (Kachh), a native state of India, within the Gujarat division of Bombay, with an area of 6500 square miles. In 1881 it had a population of 512,084, and in 1891 of 558,415, giving an average density of 86 persons per square mile. In 1901 the population was 487,384, showing a decrease of 13 per cent., due to the famine of 1899–1900, compared with an increase of 9 per cent. in the previous decade. The estimated gross revenue is Rs.25,21,670; the tribute for a subsidiary force amounts to Rs.2,00,000. There are special manufactures of silver filigree-work and embroidery. The maritime population supplies the best sailors in India. In 1897–98 the imports by sea were valued at Rs.66,69,273, and the exports at Rs.21,35,605; the customs duties amounted to Rs.8,17,000. There are ten cotton presses and two ginning factories. The number of police was 826; the number of schools was 134, with 7142 pupils, being 2·23 per cent. of the population. The chief institutions are a high school and a school of art, both at Bhuj, the capital. There are seven libraries in the state, with 7246 books. Cutch suffered severely from the recent plague.

**Cuttack,** a town and district of British India, in the Orissa division of Bengal. The town is situated at the head of the delta of the Mahanadi. Population (1881), 42,676; (1891), 47,186. It is the centre of the Orissa canal system, and now an important railway station on the East Coast line from Madras to Calcutta. It contains the Government college, called after Mr Ravenshaw, a former Commissioner; a high school, with 265 pupils; a training school; a survey school; a medical school, with 112 students, of whom 5 were women; a law school; six printing-presses; three vernacular periodicals; a Baptist mission; and a Roman Catholic convent.

The District of Cuttack lies in the centre of Orissa, occupying the deltas of the Mahanadi and Brahmani, together with a hilly tract inland. Its area is 3633 square miles. The population in 1881 was 1,795,065; in 1891 it was 1,937,681, giving an average density of 533 persons per square mile. Classified according to religion, Hindus numbered 1,881,913; Mahommedans, 52,895; Christians, 2733, of whom 128 were Europeans; "others," 140. In 1901 the population was 2,059,719, showing an increase

of 6 per cent. The land revenue and rates were Rs.10,32,983; the number of police was 571; the number of boys at school in 1896–97 was 55,351, being 39·2 per cent. of the male population of school-going age; the registered death-rate in 1897 was 33·39 per thousand. The Orissa canal system, which lies mainly within Cuttack district, irrigated in 1897–98 an area of 200,943 acres, and carried 546,766 tons of cargo. The gross receipts amounted to Rs.5,51,924, showing a net profit of Rs.12,005. The railway across the district towards Calcutta was opened in 1899. Considerable trade is carried on at the mouth of the rivers along the coast, the principal port being near the lighthouse at False Point. In 1897–98 the value of the exports (mostly rice) was Rs.25,76,728 for foreign and Rs.1,50,452 for coasting trade. The imports are insignificant.

**Cuttle-fish.**—The Cuttle-fish, whose general anatomy has already been described in the 9th edition of the *Ency. Brit.*, are classed in the sub-kingdom MOLLUSCA on account of their bilaterally symmetrical, unsegmented bodies, their possession of a fleshy integument, or "mantle," and of a muscular "foot," and the arrangement of their nervous centres in three pairs of ganglia. They are placed in the cephalous division on account of their having a distinct head, and a buccal cavity lined in almost all cases by a toothed lingual ribbon or "odontophore." Within this division they are sharply marked off as an anciently developed distinct class by the following characters. In the earliest stage of their growth a part only of the germinal substance of the ovum is segmented, instead of the whole, as is commonly the case in other molluscs. They are provided with strong parrot-like horny jaws surrounded in the Octopods by eight, and in the Decapods by ten, sucker-bearing arms; their brain is encased in cartilage; their eyes are enormous; and on their ventral side is an ejecting siphon or funnel, at the base of which lies the ink-bag. These characters combine to make them the most active, intelligent, and predaceous of all the marine invertebrates.

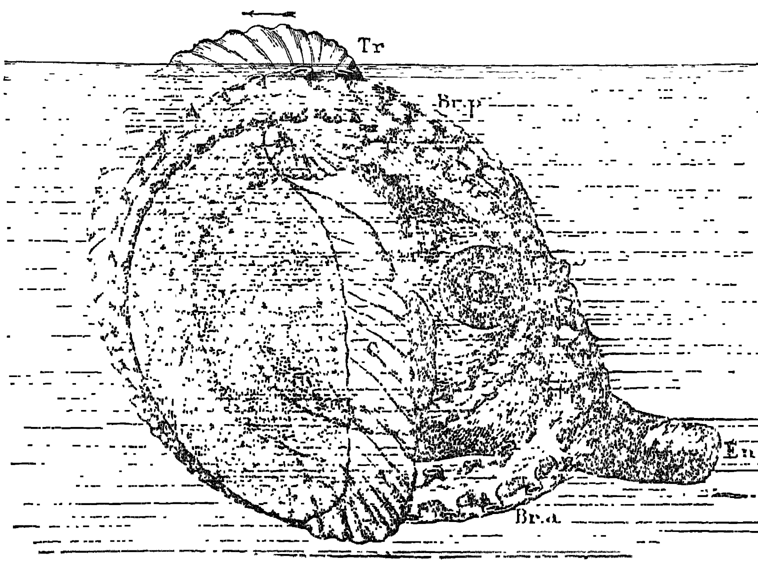

FIG. 1—The Argonaut in life. (*After Lacaze-Duthiers.*) *Tr*, float; *Br.a*, anterior arms; *Br.p*, posterior arms; *V*, the expanded portion of them, once called the sails; *B*, the beak; *C*, the shell; *En*, the funnel.

The class *Cephalopoda*, of which the general characters are thus indicated, includes as a distinct group the members of the Pearly Nautilus Order, which differ only in the living animals by minor peculiarities, as follows:—They are protected by an external camerated shell; their jaws are calcareous and of different form; their arms are in lobes, with clinging tentacles in place of suckers; their siphon is not a complete tube, and there is no ink-bag; their eyes have no lens, but only a pin-hole aperture; and they have four branchiæ instead of two, each of which is provided with a sense-organ or *osphradium*, but there are no branchial hearts. These characters indicate a less active and intelligent animal, and one less removed by development from the primitive type of the class. The number of the branchiæ has been used for the purpose of nomenclature, so that while the Nautilus Order belongs to the *Tetrabranchiata*, the Cuttle-fish Order belongs to the *Dibranchiata*. Besides these two orders there is an immense number of fossil forms, of whose branchiæ nothing is ever likely to be known, and they have accordingly been sometimes classed as Tetrabranchiates and sometimes as Dibranchiates, but they ought rather to be called Ignotobranchiates.

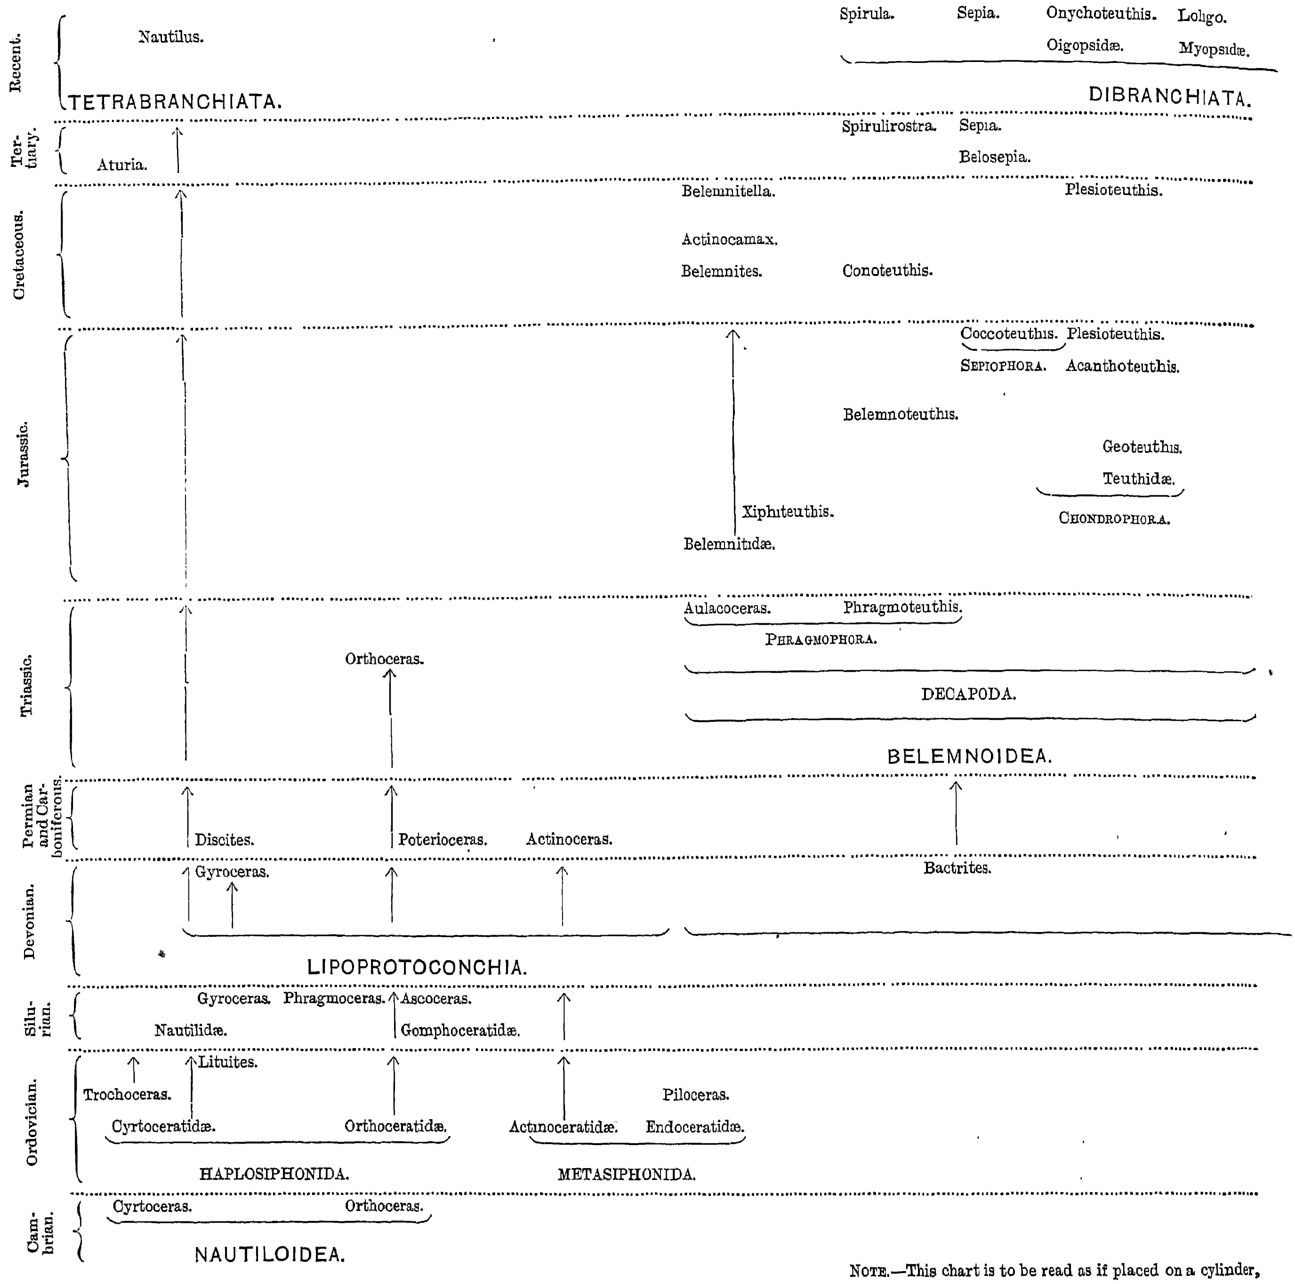
Much discussion has taken place as to the true homology of the arms and their relation to the head of the Cuttle-fish. The majority of naturalists consider the arms to be part of the "foot," which has grown up so as to surround the mouth, because they originate at the same part of the embryo as does the foot of a snail, and are innervated from a ganglion corresponding in its connexions with the pedal ganglion. In this view the siphon and its appendages form the remainder of the foot, and the animal is represented, for comparison, as standing with its head downwards and its body obliquely upwards. Others consider the siphon to represent the whole of the foot, and the arms to be organs special to the class. The origin of the arms in the development of the embryo is certainly very distinct at first from that of the siphon.

***Recent forms.***

The number of distinct forms now included amongst existing Cuttle-fish is very large, the latest census giving 464 species. These may be described as clustering principally round certain well-known types, as the *Octopus* or Poulpe, the *Sepia* or Squid, and the *Loligo* or Calamary, with a few specially isolated and interesting forms. Of these latter may be enumerated the *Cirroteuthis* and the *Opisthoteuthis*, which are finned Octopods in which no odontophore has been found, while their arms are webbed together like an umbrella; and the latter has its siphon directed backwards. These are probably retrograde forms. Others are the *Argonauta* and the *Spirula*, on which of late years fresh light has been thrown. Of the Argonaut many fables have been told as to its position in the shell, and its mode of progression, but in 1892 Lacaze-Duthiers had an opportunity of watching the living animal for a fortnight (Fig. 1). It forsakes its shell in adverse circumstances, but enters it again under favourable conditions. The front edge of the shell is then kept nearly vertical, and the early part of the coil encloses air which serves as a float. The funnel projects in front below, and the beak above, the eye. The broad pair of arms embrace only the hinder part of the shell, leaving the front part uncovered, and the other arms in swimming are tucked inside the shell between it and the body.

A well-preserved specimen of the animal of the *Spirula*, as obtained by the *Challenger* Expedition, has been described by Pelseneer. The shell is naked and exposed both on the front and back of the animal, and coils towards the ventral side, on which the siphuncle lies. The mantle sac at first

CLASSIFICATION OF CUTTLE-FISH AND THEIR



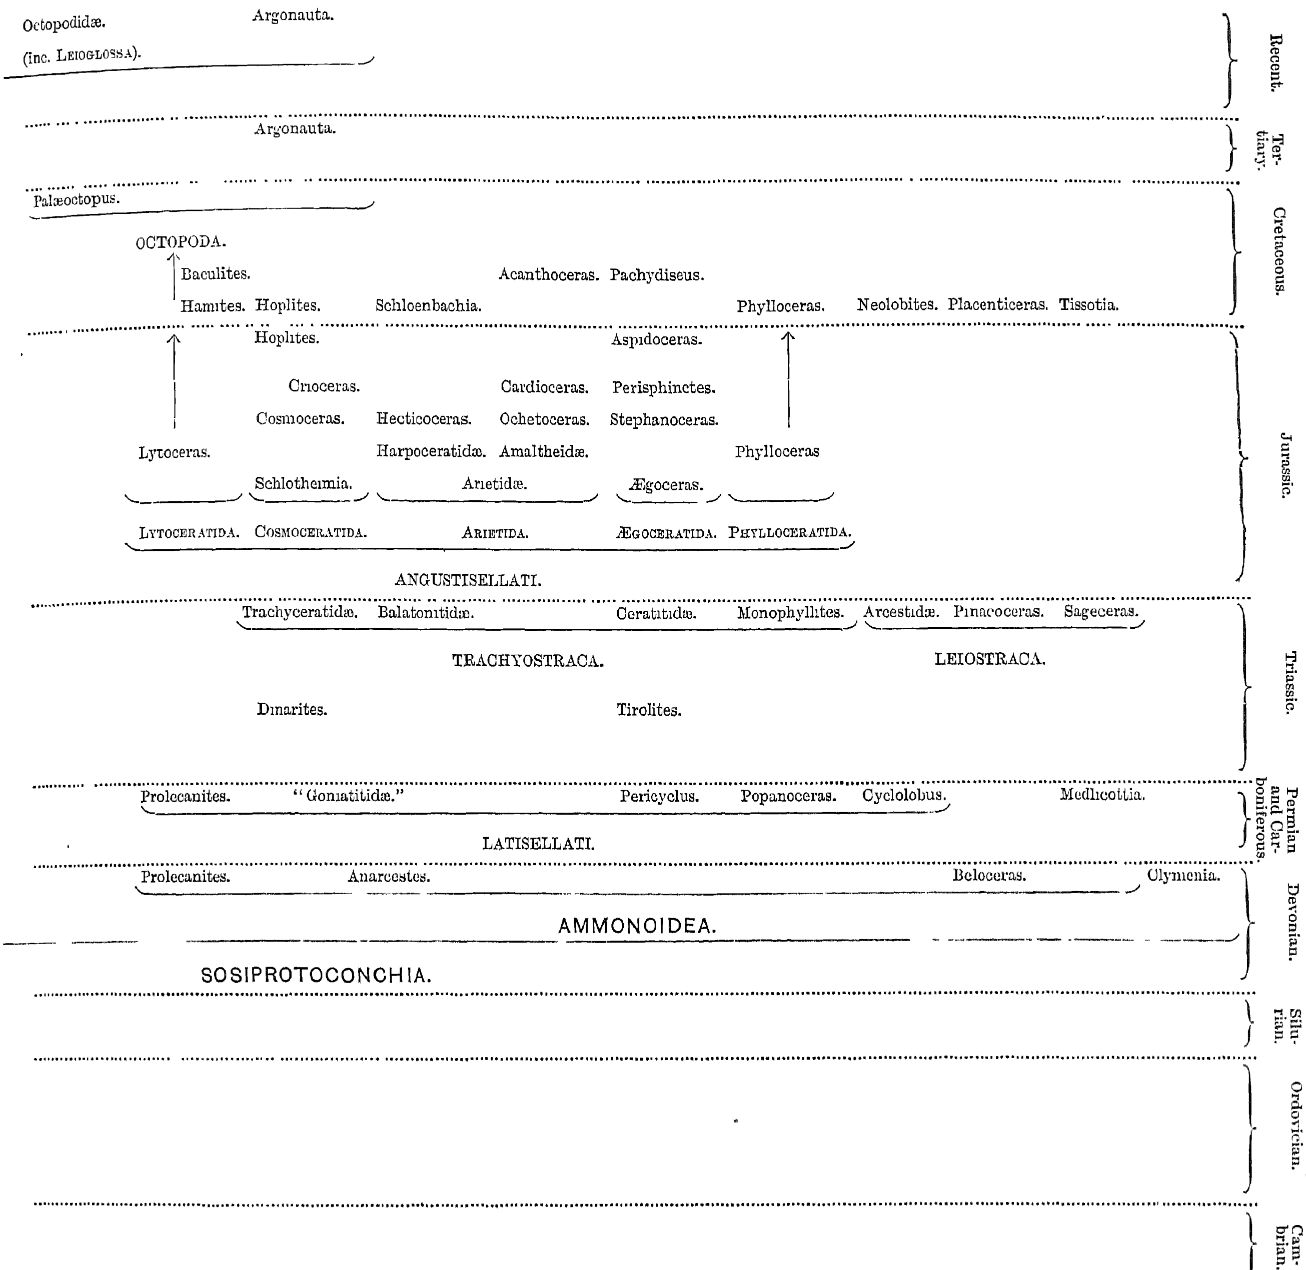
NOTE.—This chart is to be read as if placed on a cylinder,

only covers the chamber adjacent to it, but afterwards grows over the sides and coalesces below. At the base is a flat depressed disc, which is not a sucker, but may be a pad to prevent shocks in swimming backwards. At the sides hang two fins which are parallel to each other, in the direction from back to front and not in one transverse line behind. The ovary lies against the right-hand side of the coil of the shell and the oviduct against the left, and the last chamber is occupied by part of the liver. The eyes are on peduncles sunk below the level of the head, but are not covered, as in higher groups. The *Spirula* thus represents an early stage in the development of the Order.

The shells of the Cuttle-fish Order, on which we principally depend for our knowledge of their relations to fossil forms, are not in great variety at the present day, but the *Spirula*-shell itself suffices to connect them on the one hand with the Pearly Nautilus, and on the other with an infinite series of extinct allies. The *Spirula*, like the Nautilus, has its shell in the form of a conical tube, coiled in one plane and divided by cross partitions—the "septa"—into chambers connected by an inner tube—the "siphuncle." Fossils showing these same general characters can be traced back to the earliest fossiliferous or Cambrian strata. With these, as the primitive ancestors, the history of the Cuttle-fish commences. These earliest forms of shell are, as might be expected, very simple. The tube is oval or round, the coiling is slight (*Cyrtoceras*), or absent (*Orthoceras*), the septa mere shallow basins, the siphuncle a simple narrow tube with no fixed position, and the ornaments no more than lines of growth. In the later history we find one after another of the several elements becoming a centre of variation, till fixity is reached, or the element, or even the shell itself, is dispensed with. The first element to vary was the siphuncle, the complexity of which gave rise to such early genera as *Endoceras*, *Piloceras*, and *Actinoceras*, forming a separate group, METASIPHONIDA, the remainder

**Extinct forms.**

ALLIES DURING SUCCESSIVE EPOCHS.



like a map of the World on Mercator's projection.

being Haplosiphonida. This condition of things continued to the Carboniferous period, after which no complex siphuncles are known; the organ then became insignificant, and is finally lost in all the recent Cuttle-fish except the *Spirula*. The position of the siphuncle was variable at first, and in those forms which are the special ancestors of the Nautilus it continued to be so. But in Devonian times a cleavage of the class took place, and a new group was developed, in which the siphuncle is permanently pushed to the ventral side in the adult, where it is also now found in the archaic *Spirula*. This group is also characterized by having a thin and fragile shell, and by the peculiarities of the initial chamber or *protoconch*, which is of globular form, has a restricted neck, and contains the commencement of the siphuncle at its centre, as seen in *Spirula*. We thus obtain two great subdivisions of the Class: on the one hand the Nautiloidea, presumably tetrabranchiate and certainly less progressive; on the other, the remaining Cephalopoda then existing. The only collective name yet suggested for this new group, unless we assume them all to have belonged to the Dibranchiata, is the Sosiprotoconchia of Bather, who calls the Nautiloids at the same time Lipoprotoconchia. As the Cuttle-fish proper must have descended from these Sosiprotoconchia, we need follow the Nautiloids no more.

Within the *Sosiprotoconchia* there was soon a new and fundamental cleavage dependent on the variation of the coiling. On the one side are the *Belemnoids*, which have practically no coiling at all, and whose fragile shells are protected, if at all, by a massive external guard, while their septa remain simple; on the other side are the *Ammonoids*, whose globular protoconch is closely enveloped by the later coils, which often overlap each other and whose septa become complex, their surface being partially convex forwards, and their edges or "sutures" folded or wrinkled.

Both these modifications seem adapted to give greater strength in relation to a more active life.

The modern Decapod Cuttle-fish are undoubtedly the descendants of the Belemnoids. The earliest of these belong to Triassic times where they are known as *Aulacoceras*, *Atractites*, and *Phragmoteuthis*. It is very probable that there were earlier, as yet undiscovered, representatives, and that a cleavage had already taken place, for in the succeeding, Liassic, period a new group is well established. In this group, the *Chondrophora*, all signs of the original septate shell are lost, and the protecting pen, now horny, alone is left. The genera, known as *Teudopsis*, *Beloteuthis*, *Geoteuthis*, &c., differ in little beyond their broader pens from the modern Calamaries, so that they rapidly attained their acme of development, and then remained stationary. The other group, the *Phragmophora*, developed the *Belemnites* proper. These retain throughout their whole development the original thin shell—or "proostracum," its internal septa and siphuncle forming together the "phragmocone." It is the guard that changes, either in form or markings. It is very feeble in *Belemnoteuthis* and said to be absent in *Conoteuthis*; it commences to be absorbed in *Belemnitella*, and is caducous in *Actinocamax*. So far we are on safe ground, for the Belemnites were certainly Cuttles, since their guard is known to have been internal, by its earlier layers being enveloped by the later ones; and further, they are found with the guard in position at the extremity of a perfectly outlined body with characteristic fins, ten arms with hooks, ink-bag, and eyes.

The history of the divergence from the general Belemnoid type into the two branches represented respectively by the *Spirula*, with phragmocone and no mucro (or modified guard), and the *Sepia*, with mucro and no phragmocone (unless the cancellous tissue represent it), is obscure. For the only possible suggestion for an ancestor of the former would be the doubtful *Conoteuthis*, and the latter is said to have a near ally in *Coccoteuthis* of the Solenhofen limestone. Both of these are anterior to the disappearance of Belemnites, so that it is not certain whether the latter have been modified into, or superseded by, the representatives of the modern Cuttles. Nor is it clear whether the peculiar cancellous substance in the *Sepia* represents a series of modified septa, or of special shell layers. Each lamella is supported by sinuous partitions rising vertically from the one below, and these appear to spread out horizontally at intervals and coalesce to form the new lamella, the whole being calcified in horizontal layers. The spaces bounded by the calcified partitions and the lamellæ are occupied in the very fresh shell by a number of thin walled, apparently empty, cells in two or more horizontal layers, whose adpressed walls give the appearance of free membranes, but these are without regularity. It is probable that these secrete some gas, so that the lamellæ coincide in function, if not in origin, with the septa of a phragmocone.

The history of the Ammonoids, including their probable modern representatives, the Octopods, is more complex. In this group the first element to form a centre of variation was the septum, and its outline the suture. This variation in the early stages of growth has been made the basis of Branco's classification into the *Asellati*, *Latisellati*, and *Angustisellati*; in the later or adult stages it gives the principal generic characters of the *Goniatite* and *Ceratite* groups, and of those remarkable forms of the Trias in which it reaches its acme of complexity, as in *Sageceras*, *Pinacoceras*, and the *Arcestidæ*. After this, the Ammonoids settle down into a "normal" type of suture, which, though showing abundant differences of detail, can all be described, without straining, as modifications of a definite arrangement of "lobes" and "saddles." The centre of variation next passes to the build and ornament of the external shell. Whilst the sutures were the principal seat of variation the shells remained smooth—*Leiostraca*; now they became ornamented or rough—*Trachyostraca*; doubtless this, on the principle of corrugated iron, made them stronger and less dependent on their septa. From these latter the majority of the later Ammonoids have descended, the genera depending principally upon the build and ornaments, so called, of the shell; till in Cretaceous times their abnormal forms, *Hamites*, *Baculites*, &c., indicate their decadence and presage their disappearance. Other abnormal forms have, however, appeared at various epochs of Ammonite history.

What became of the Ammonites? and whence are the Octopods derived? are two correlated questions on which more light is desirable. The wide distribution of Ammonites in all latitudes and in all varieties of strata, shows that neither change of temperature nor of circumstance can have caused their extinction. The forward convexity of their septa suggests the secretion of gas at great depths which expanded as they rose to the surface before the last septum was fully formed. In this case they must have been pelagic animals, and therefore have been superseded by other pelagic animals performing their function more efficiently—such as more highly developed members of the same class.

It is now known that Octopods were actually in existence in the Cretaceous period, thus overlapping the

Fig. 2.—*Palæoctopus Newboldi*, the oldest Octopod known. From the Cretacious rocks of Lebanon. (*After H. Woodward.*)

Ammonoids in time, since a member of that group, the *Palæoctopus* (Fig. 2), has left an impression of its body, head, arms, and two fins, as in the *Pinnoctopus*, on rocks of that age in the Lebanon. This was naked, so that in part of the group the shell was already dispensed with. On the other hand we have in the living Argonaut an Octopod whose shell has a great external resemblance to

that of an Ammonite, particularly to such an early type as the *Trachyceras*, or late type as the *Hoplites*.

It has usually been considered, but not without various protests, that this resemblance is superficial only, since there are no septa, and the shell has been supposed to be the product of the arms which partially embrace it. That such is not the case has been shown by Steinmann, and can be easily verified on the shell itself. The most solid part is a transverse bar, projecting from either side of the apex and spreading out in a double fold over its surface. It is actually inaccessible to the arms, and cannot be produced by them. This bar passes insensibly into the remainder of the shell, which consequently has the same origin. This is composed of two principal layers. The inner layer is a comparatively thin basement membrane, irregularly folded and thickened by calcareous matter in irregular lines running parallel to the margin of the shell, and in no way interrupted in passing from one side to the other of the median line. The outer layer, which has a tendency to split into two parts, consists of very fine vertical rods, arranged as in a pile carpet, which readily coalesce and are calcified into the solid shell. It is these two layers that are produced by the mantle. Besides these there is a thin amorphous periostracum, often coloured with a brownish tint and rough on the surface from the sporadic deposit of calcareous particles. This is found only on the outside of the shell where it is covered by the arms, that is, it is wanting near the margin and for some distance on either side of the median line.

The relation of this shell to the animal is similar to that of the Nautilus, and thus presumably of the Ammonite also, and different from that of the Sepia, inasmuch as the outer part of it lies on the siphonal or ventral side of the mouth; while in the Sepia it lies on the antisiphonal or dorsal side. Such is the evidence at present available for the view that Octopods are descended from Ammonites which have dispensed with their septa, or with their entire shell. On the other hand is the fact that no ink-bag has ever been found in association with an Ammonite.

(J. F. BL.)

**Cuxhaven,** a seaport town of Germany, belonging to the state of Hamburg, and situated at the extremity of the west side of the mouth of the Elbe, 71 miles by rail north-west from Hamburg. A new harbour was made in 1891–96, having an area of 71,800 square yards and a depth of 26½ feet, with a fore port 1000 feet long by 800 feet wide; and it is now the place of departure and arrival of the mail steamers of the Hamburg-American Steamship Company, who in 1901 transferred here a part of their permanent staff. The port is free, *i.e.*, outside the Customs Union (*Zollverein*), and in 1899 was entered by 331 vessels of 73,090 tons; the imports being principally coals, bricks, and timber, and the exports fish. There is a fishing fleet, for which a new harbour was opened in 1892. Population (1900), 6898.

**Cuzco,** the largest department of Peru, with an area of 156,270 square miles and a population of 438,646. It contains twelve provinces—Convención, Urubamba, Talca, Puacartamba, Anta, Cuzco, Quispicanchi, Paruro, Acomayo, Chumbivilicas, Canas, and Canchis. The capital, Cuzco, has a population of 30,000.

**Cyclades.** See GREECE (*Ionian Islands*).

**Cycling.**—The history of the pastime, the sport, and the trade of cycling really begins with the year 1885. The method of self-propulsion upon two, three, or four wheels—bicycles, tricycles, or multicycles—has been practised, with more or less perseverance, for at least a hundred years. But before 1885 its votaries were either athletes, or persons carried away by a temporary craze; either venturesome pioneers, balancing and propelling themselves, with varying degrees of speed and uncertainty, upon "boneshakers" and "ordinaries," tall bicycles, or the timid, sometimes the comfort-loving, who rode tricycles, velocipedes, or multicycles. Had it not been for the practical and commercial introduction of the safety bicycle, brought out by J. K. Starley, of Starley and Sutton, in 1885, cycling would never have gained its popularity or become a universally recognized method of locomotion. The invention of the safety bicycle is claimed by numberless inventors. From 1818, the year of the craze for the Draisnene of Baron Drais de Saverbrun of Mannheim, who propelled his bicycle by half-sitting, half-standing upon a bar fitted with a saddle, connecting two equal-sized wheels, with a handle in front for steering and also for rest, and by pushing with his toes which just touched the ground, until 1840 and 1846, when Kirkpatrick Macmillan, a blacksmith of Dumfriesshire, and Gavin Dalziel, a cooper of Lanarkshire, fitted cranks and pedals to these Draisnene or similar vehicles, there is no authentic historical record. It has also been asserted that similar machines were used in Paris in 1816, one by M. Niepice in the Luxembourg Gardens. There was also a machine shown in the historical collection in Class 30 at the Paris Exhibition of 1900, which was stated to have been made in 1799, but there is no authentic proof of the correctness of any date before 1818. Macmillan's and Dalziel's machines had pedals, which moved levers backwards and forwards, connected with the rear axle, and thus drove them. Credit, therefore, for the invention of balancing and rear driving seems to belong to Macmillan; for direct steering to Baron Drais. By 1855 cranks and pedals had been affixed to the front wheel, which was driven, and in 1866 came Michaux with his velocipede, a heavy lumbering

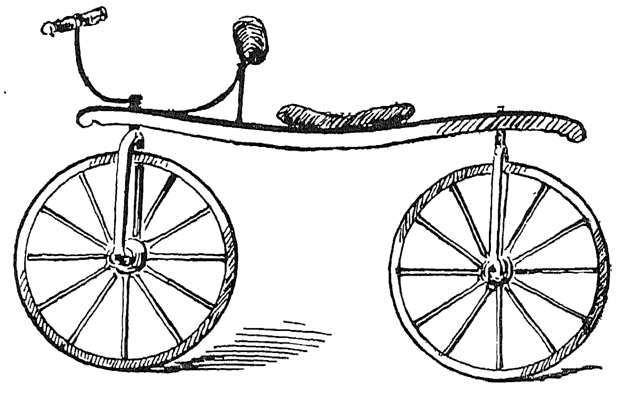

FIG. 1.—Gentleman's Hobby Horse, 1816–30.

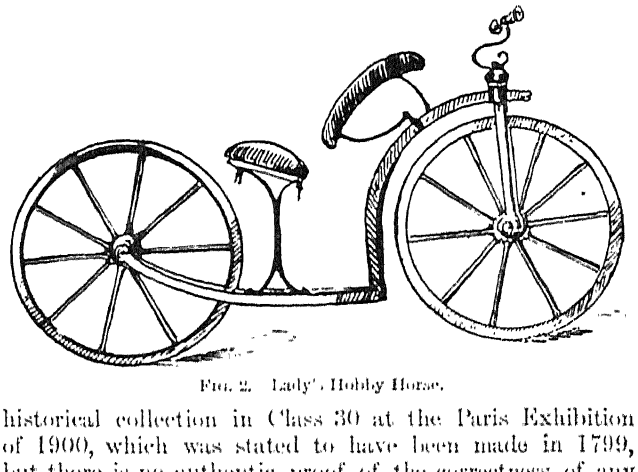

FIG. 2. Lady's Hobby Horse.

affair of steel, iron, and wood. The rider sat upon a wooden or iron frame, or a long steel spring connecting the wheels, and he propelled and steered the cycle, known as a bone-shaker, by the front wheel. In 1866 also, Pierre Lallemant took out in the United States a patent for a wheel driven by a crank and pedals; this patent was upheld for many years, and later it had much to do with the development, or want of development, of the American cycle industry. A similar patent was granted to E. Gillman in England a few months earlier. Lallemant's machine was shown by Michaux in the Paris Exhibition of 1867. In the same year the first modern machine with a large wheel in front is said to have been made in England, but the maker's name is unknown. Crank-action, however, had been applied to velocipedes with three or

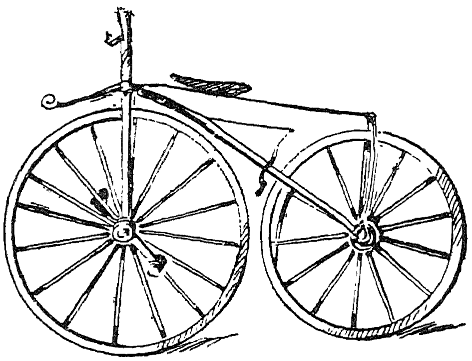

Fig. 3.—The Boneshaker, 1868.

four wheels many years before. In 1868 the bone-shaker was imported into England from Paris by Mr Turner. And in 1869 Michaux is reputed to have produced in France the first bicycle with a big front wheel, the "ordinary." These two statements seem contradictory, but it would be impossible to prove, or disprove their truth at the present time—that is, to prove whether the bicycle with the large front wheel was first made in England or in France. There is no doubt, however, that the tall bicycle was at first used more generally in England. There was unquestionable delight and pleasure in riding this machine, and very long tours and very fast times on the road and path were made on it. H. L. Cortis covered 20 miles 300 yards in the hour, in 1882. In 1884 Thomas Stevens started from San Francisco to ride round the

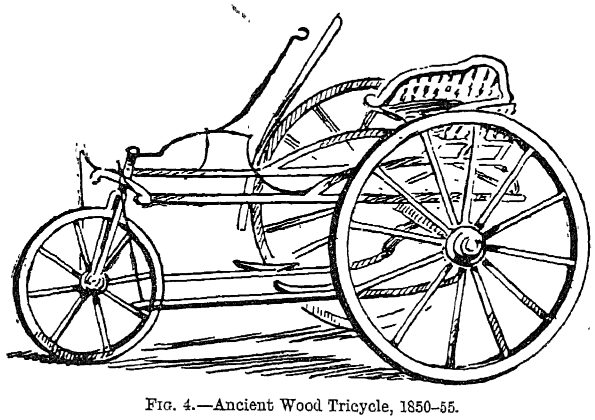

Fig. 4.—Ancient Wood Tricycle, 1850–55.

world, a feat of most surprising pluck, energy, and endurance, which he accomplished in three years. Endless attempts were made to produce dwarf or safety bicycles which should combine the safety of the tricycle with the speed of the ordinary. Among the most popular were the "Extraordinary Challenge," the "Facile," the "Kangaroo," the "American Star," but, though they possessed scarcely greater safety than the ordinary, they were very complicated, and have all disappeared. Starley's "Rover," however, was safe, and was a success from the start. He returned to the form of the "Draisnene," but the "Rover" was driven by a chain carried on a gear wheel, so that the

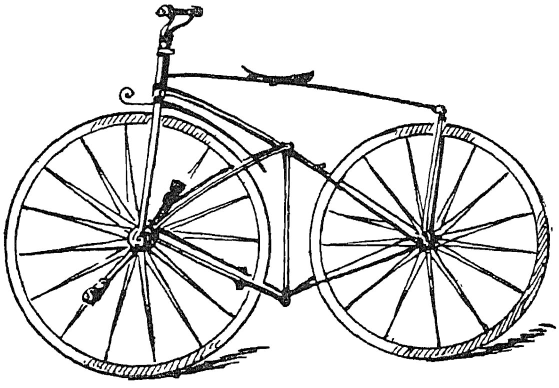

Fig. 5.—The "Phantom," 1869.

rider by one revolution of the pedals propelled his cycle as far as or farther than the rider of the tall ordinary. This chain travelled from a crank axle, fitted between the two wheels, to the hub of the back wheel, and the machine was steered by the front wheel. Save in structural details the safety is the same to-day as in 1885.

About 1870, or possibly before — the exact date is unknown — steel suspension wheels had been substituted for wooden spokes, and solid rubber for iron tyres. But even with rubber tyres (by 1887 to 1888 large cushion tyres had been fitted to the wheels and powerful springs to deaden vibration added to the frame) the progress of the cyclist along the road was anything but pleasant. The vibration on the tall bicycle, produced by the small back wheel, often only from 14 to 18 inches in diameter, though the front wheel had grown from 50 to 60 inches, was most trying, and the jolting on the safeties, with their tiny tyres, was almost equally bad, producing not only nervous exhaustion and fatigue, but, with most people, ultimate

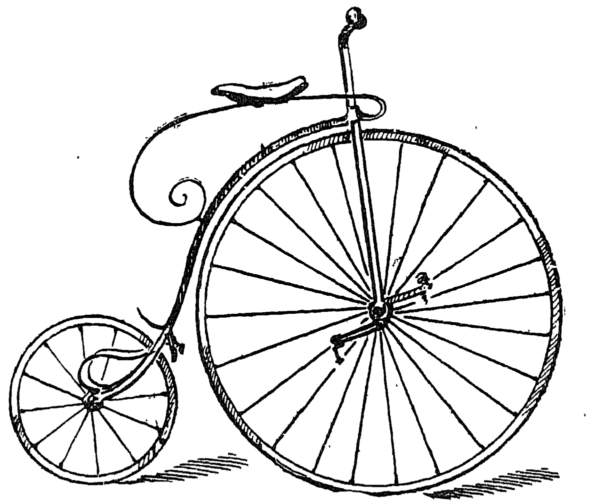

Fig. 6.—Grout's Tension, 1871.

distaste for the pastime. Sir Benjamin Ward Richardson was the first to draw serious attention to the mental and physical danger of vibration. But no satisfactory solution was to be found. The safety not infrequently was totally unmanageable. The frames had no uniformity. They were either made in a series of curves, or with two crossed tubes like an open pair of scissors stayed by wires. The diamond frame, now universal, was faintly suggested by imaginary lines, and the diagonal one was unthought of.

In 1888 a veterinary surgeon of Belfast, J. B. Dunlop, substituted for the solid, or cushion tyre,—the latter a much enlarged rubber tyre with a hollow core, both of them cemented to the rim,—a bandage composed of a rubber tube, about two inches in diameter, vulcanized or solutioned to a canvas cover, which encircled the whole rim and was then inflated by an air pump. The idea was not new; in 1846 Mr William Thompson had taken out a patent for a pneumatic tyre, for carriages, little used at the time and afterwards completely forgotten. Upon a machine fitted with the Dunlop tyre, races were won by Messrs Ducros in Ireland in the spring of 1888, and also at an autumn meeting of the Surrey Bicycle Club at the Kennington Oval in the same year, while a few tourists made experiments with the new tyre on the road. It was at once seen that

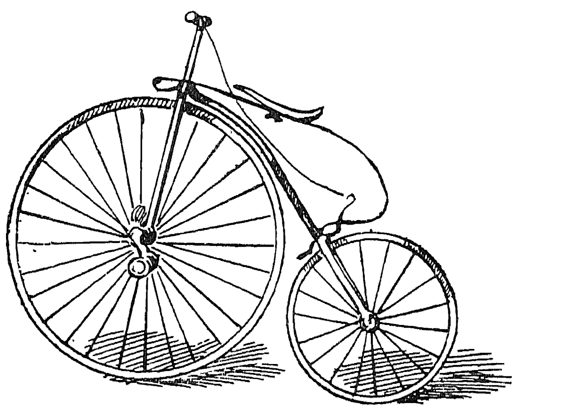

FIG. 7.—Humber's "Spider," 1872.

not only had vibration been greatly lessened, but speed wonderfully increased, and this invention of the veterinary surgeon, who did not even ride a bicycle, when applied to the safety, gave cycling its universal popularity. Within a few years the ordinary or tall front-driven bicycle and the tricycle almost disappeared. The former has gone almost entirely save as a dwarf, and the latter only survives as the carrier, though a certain number are still manufactured of the Humber Cripper type. The safety also solved the problem of women cycling without being compelled to adopt male attire. There was an attempt to change women's costume, and for safety and ease such a radical change might be an improvement. But the general feeling, warranted by the general result, when the experiment was made, was against it. Women had for years ridden the tricycle. But tricycles weighed ordinarily from

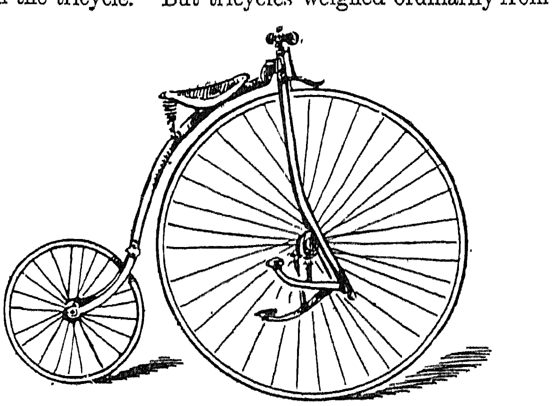

FIG. 8.—The "Facile," 1879–84.

60 to 100 ℔ or more, and were therefore unsuitable for them, unless in the form of tandems and sociables, on which the greater part of the work was usually done by a male rider. Still, as far back as 1883 or 1884 the whole of Europe had been covered by women on tricycles. Bicycles for women were introduced about 1887 or 1888 by Starley Brothers, the makers of the "Psycho," and by 1890 or 1891 they had been generally adopted. The first machine of this sort is said to have been made by J. M'Cammon of Belfast in 1884. Tandem bicycles first became practical about 1889 or 1890, and in a few years

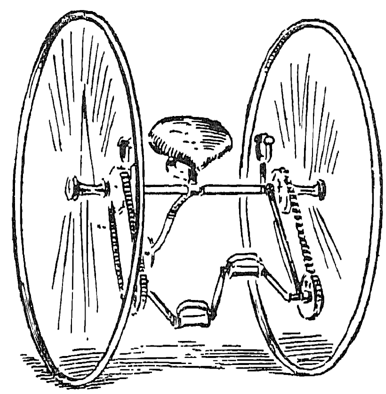

FIG. 9.—Otto Dicycle, 1879.

they virtually superseded the tandem tricycle. Save that they are strengthened and simplified in construction there is little change in them. Certain makers of cycles deserve to be remembered. A few names will always stand out prominently. Among them are D. Rudge, Thomas Humber, James Starley, for his balance gear, W. Bown, the inventor of ball-bearings, and J. K. Starley—men who more than any others impressed their inventive genius on the industry and the trade, though the present mechanical position of the cycle industry is the result of the untiring labour of multitudes of inventors everywhere. J. K. Starley, practically and commercially, made the safety bicycle in 1885. But nine years before this, in 1876, Messrs Henry Bate and George Shergold were working at the safety idea, Bate by gearing up, Shergold by means of a small front wheel. In the same year, too, Mr H. J. Lawson patented a lever-driven safety, but the rear wheel was from 50 to 84 inches, and, in 1879, he produced Lawson's bicyclette. This, however, was, in many details, very like the bone-shaker of a few years before, though it had a small back wheel which was geared up and chain-driven.

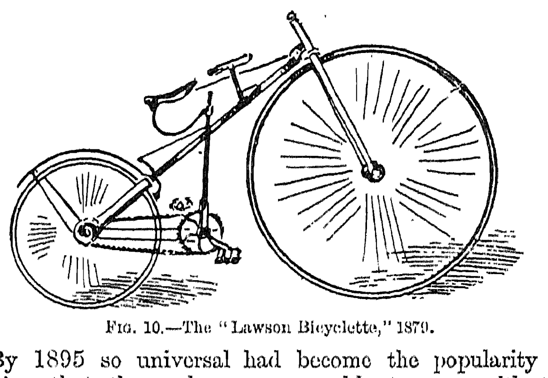

FIG. 10.—The "Lawson Bicyclette," 1879.

By 1895 so universal had become the popularity of cycling that the makers were unable to cope with the demand. New factories were started, small shops grew into large companies, and where the capital invested in them before had been reckoned by hundreds it speedily became millions. Nor was the new activity confined to cycles alone or to Great Britain. Tyres, component parts, lamps, saddles, every sort of accessory, acquired enormous financial importance. The Dunlop Co., started in 1889 with a capital of £25,000, was floated in 1894 for £5,000,000.

The makers who by their mechanical genius had brought the manufacture of cycles well on the way towards perfection, each one striving to improve his own detail, were now swallowed up by company promoters and adventurers, bent simply upon lining their own pockets, at any cost, by supplying a world which had suddenly gone cycle-mad. The result was that energy was mainly turned to the payment of dividends by the grossly over-capitalized companies. Machines, instead of being built by mechanics proud of their work, in many cases were simply put together in the shortest possible time, and turned out in the greatest possible numbers in one or more standard patterns. For these the world clamoured, and for a year the makers could not produce them fast enough. In another year the demand decreased. The inventive spirit had become dormant, the British market was over-stocked, and, as the British manufacturers refused to consider the wants of foreign customers, their store rooms remained crowded with unsold machines, dividends were unpaid, and all but the strongest firms went to the wall. Although cycling remained as popular as ever, the trade became disorganized, through seeking, frequently by cheapness and the resurrection of antiquated ideas, to bolster itself up, rather than by individual excellence to regain its lost position. The only attempt to meet individual requirements was to be found among a few makers who built cycles to fit their riders, as was done at the very beginning of the industry. A similar state of affairs, more or less, exists in almost all other countries. In America a huge trust was organized, by which it was hoped that the wants of manufacturers, rather than the desires of purchasers, would be promoted. But ever since Lallemant's patent was purchased by one company, and sustained, it has been the effort of the American cycle makers to compel riders to purchase machines made in the fashion which was most profitable for them. Hence dropped steel forgings, wood rims, and single tube tyres were for a time all but universal in America. As American cycles are made by the most perfect automatic machinery, and as the parts can be duplicated, the whole of Europe, as well as America, for a year or two, was all but monopolized by the manufacturers of the United States. They, however, paid little more attention than the English makers to European wants, so that they, too, began to lose their hold. With the 20th century, however, the outlook became more hopeful.

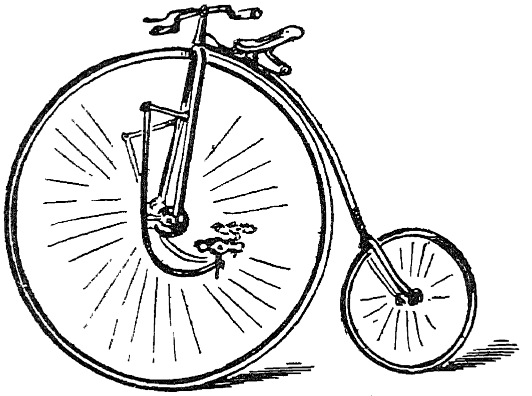

FIG. 11.—Singer's "'Xtra," 1879.

Although cycle tours were taken and cycle clubs established almost as soon as the cycle appeared (the Pickwick Bicycle Club of London was founded in 1870, and is the oldest bicycle club in the world), and although the Cyclists' Touring Club, then known as the Bicycle Touring Club, was organized in 1878, it was not until 1895 that this organization assumed its present importance. To-day it numbers about 56,000 members, scattered throughout Europe and America and even the East. It is the only international organization of the kind, though almost every other country possesses a national club. The League of American Wheelmen, started in 1880 in a very small way, was able, after a period, to claim a membership of over 100,000, a degree of prosperity which it could not maintain, for by 1900 its members had dwindled to 28,000. The Touring Club de France, founded 1895, at the present time is numerically the strongest, with 72,000 members, but cycling is only one, if the chief, of its objects. An International Touring League has been formed by the national clubs, and it numbers a quarter of a million members. The aim of these associations is the promotion of cycle touring. They publish road-books, maps, and journals; they recommend hotels in their own and other countries with fixed tariffs; they appoint representatives to aid their members when touring; and they have succeeded in inducing most governments to allow their members to travel freely across frontiers without paying duty on their cycles. Another important branch of the work of these clubs, either directly or indirectly, is the improvement of the roads. This is accomplished either, as in Belgium, where all the roads are paved, by the taxation of cycles and the consequent demand on the part of riders for side paths; or by grants of money, as in France, to aid the State; or, as in Great Britain, by the publication, through a body known as the Roads Improvement Association, of good-roads literature, and by watching, promoting, or suppressing, when possible, various parliamentary and local government and railway bills affecting cyclists. In the United States also the League of American Wheelmen is devoting itself more and more to the good-roads question with satisfactory results, laws for improved road legislation having been passed in many states. The clubs have in all countries erected a system of warning-boards upon dangerous hills. In France even the best route is suggested by a sign-post, while cyclists who come to grief in lonely places find a repair outfit for their free use. The large touring organizations have therefore, to a great extent, superseded the old clubs. If these still exist in a quiet way—a few possessing well-appointed club-houses—they have lost their usefulness, now that all the world cycles, and survive merely as social organizations. The Stanley is an exception. It continues to promote the large annual show of cycles, held almost regularly since 1877, the makers of England and other countries having borrowed the idea, until the big yearly exhibition of machines has become an institution everywhere.

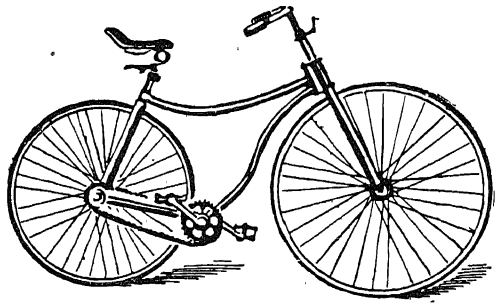

FIG. 12.—The "Rover," 1885.

Each country also possesses an organization for the government of cycle racing; and although these unions, one object of which—usually the main one—is the encouragement of cycle racing and cycle legislation, boast an enormous membership, their membership is often composed of clubs and not individuals. Among the most important are the National Cyclists' Union of England and the Union

Vélocipédique of France. These bodies are also bound together by the International Cyclists' Association, which is devoted mainly to the promotion of racing and legislation connected with it all over the world. The National Cyclists' Union, originally the Bicycle Union, which was the parent body of all, formed in February 1878, was the first to put up danger-boards, and also was early instrumental, alone and with the C.T.C., in framing or suggesting laws for the proper government and regulation of cycle traffic, notably in establishing its position as a vehicle in securing universal rights, in endeavouring, again in conjunction with the C.T.C., but unfortunately with little success, to increase facilities for the carriage of cycles on the railways, in securing the opening of parks, and in promoting many other equally praiseworthy objects. For a number of years, however, it has been more prominent as the ruling race-governing body. But cycle racing has fallen upon

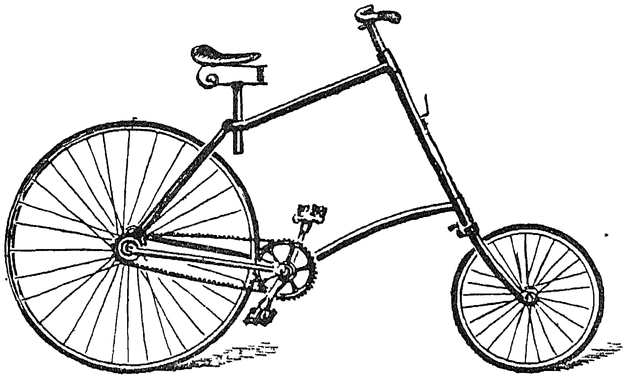

Fig. 13.—The Humber Pattern Safety, 1888.

the same evil days as cycle making. As in all other forms of sport, racing apparently occupies a great deal of public attention, and at one time a cycle race drew a large number of spectators, but now it has lost the public favour, or rather it is ignored by the public. The reason is that cycle racing has been mainly an advertisement for cycle makers. The presence of the man, directly or indirectly, in the employ of, or aided by a maker, and the consequent mixing up of trade and sport, have lowered racing not only in the public estimation, but in that of all genuine amateurs. There have always been a few amateurs who have raced for the love of the sport, but the greater number of prominent racing men have raced for the benefit of a firm, so much so that, a few years ago, an entire section of racing men were classed as "makers' amateurs." They did not confine themselves to the race track, but appropriated the public roads until they became a danger and a nuisance, and road-racing finally was abolished, though record rides, as they are called, are still indulged in, being winked at by the police and by the cycling authorities. The makers' amateurs at least rode to win and to make the best time possible. But the scandal was so great that a system of licensing riders was adopted by the N.C.U., and if this did not effectively kill the sport, the introduction of waiting races did. There probably is considerable skill in riding two-thirds of a race as slowly as possible, and only hurrying the last part of the last lap, but it does not amuse the public, who want to see a fast race as well as a close finish. This also accounts for the fact that some of the early records have not yet been beaten. The introduction of pacing by multicycles and motors next took from cycle racing what interest was left. A motor race, in which the machines are run at top speed, is more exciting than the spectacle of a motor being driven at a rate which the cyclist can follow with the protection of a wind-shield. In America this system of proving what cyclists can do with racing machines, has been carried so far that in 1899 a board track was laid down on the Long Island railway for about two miles between the metals, and a cyclist named Murphy, following a train, and protected by enormous wind-shields, succeeded in covering a mile in less than a minute in the autumn of 1900. W. Stinson covered forty miles in an hour on a safety, thus doubling Cortis's record on the tall machine. Other cyclists have devoted themselves, at the instigation of makers, to the riding of a hundred miles a day every day for a year. It would be difficult to say what advantage there is in these trials and contests. They are not convincing records, and only prove that some people are willing to take great personal risks for the benefit of their employers. E. Hale during 1899–1900 covered 32,496 miles in 313 days. For many years also long-distance races, mostly of six days' duration, have been promoted on covered tracks. Though condemned by all cycling organizations, they find a great deal of pecuniary support. Racing is probably at the present day in the most flourishing condition in France, where more money is offered in prizes on the track, the city of Paris granting funds for the purpose, and where also, on certain occasions, as in the race from Bordeaux to Paris, held annually in May, the high roads are given up unreservedly for twenty-four hours to a carnival of recklessness.

The cycle has also been taken up as a war machine. For this idea the army is indebted to Colonel A. R. Savile, who in 1887 organized the first series of cycle manœuvres in England. Since then military cycling has been continued and somewhat encouraged by the organization of cycling sections among volunteers and a special corps, the 26th Middlesex, and to a less extent in the regular army. On the Continent cyclists are attached to many army corps, if not to every regiment, as scouts, messengers, and despatch-bearers, in which capacity they may at times be of great use.

Cycling has produced a literature of its own, both of the pastime and of the trade. Owing to the enormous profits which, for several years, were obtained by cycle makers, a trade press appeared which simply lived by, and out of, its advertisers; and though each country has one or more genuine trade journals, the large proportion of these sheets have been worth, in a business aspect, as little practically, as from a literary standpoint. On the

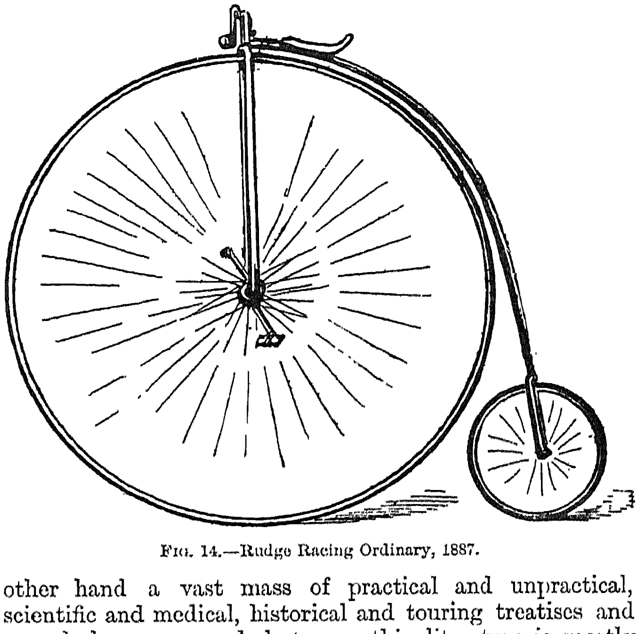

Fig. 14.—Rudge Racing Ordinary, 1887.

other hand a vast mass of practical and unpractical, scientific and medical, historical and touring treatises and records have appeared, but even this literature is mostly of a rather ephemeral character.

The history of cycling on the continent of Europe and in America is virtually a repetition of the happenings in Great Britain. Though the invention of the modern cycle is probably due to Michaux, a Frenchman, cycle-making reaches its greatest perfection in England. Improvements in many ways have been made in France and America, but English cycles of the best makes are still regarded as the most trustworthy. France, however, has done more for the cyclist than any other country, owing to the fact that she possesses the best roads, kept up to a certain extent by the cycle tax, thus giving the cyclist a certain official position and right; moreover, cycles are conveyed free on railways, and State aid is given to the sport and the pastime, with the result that trade for some years has been in a very flourishing condition. In Germany, Italy, Switzerland, and Holland much the same state of

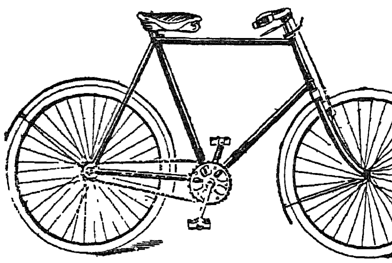

FIG. 15.—Safety, 1901.

affairs exists, though in a lesser degree. In Belgium the cycle has worked a veritable revolution in the national life. The surface of the greater part of the country is loose and sandy, and the roads therefore have been all paved, and are impossible for light traffic, because the paving is so bad. The cycle tax consequently has been devoted, first, to the construction of cycle-paths, on which wheelmen have equal rights with pedestrians, and secondly, to the replacing of the paving by macadam. In this way alone cycling has proved of inestimable benefit to Belgium and Luxembourg. In the United States also, though it has not yet been possible to procure uniform legislation, good-roads and side-path Bills have been introduced in various states, mainly at the instigation of wheelmen, while state aid has been obtained by law for the free carriage of cycles.

*World's Records in 1900.*

The following are the world's records to the end of 1900, which have been accepted by the Union Cycliste Internationale :—

| Miles. | Time. | Holder and Place. | Date. |
|---|---|---|---|
| $\frac{1}{4}$ flying | 20″ | Major Taylor at Chicago | Nov. 9, 1899 |
| $\frac{1}{4}$ standing | $27\frac{2}{5}$″ | Green at London . . | Aug. 2, 1899 |
| $\frac{1}{2}$ flying | 41″ | Major Taylor at Chicago | Nov. 10, 1899 |
| $\frac{1}{2}$ standing | $51\frac{1}{5}$″ | Green at London . . | Aug. 2, 1899 |
| $\frac{3}{4}$ flying | 1′:$04\frac{3}{5}$ | Chase at London . . | July 26, 1900 |
| $\frac{3}{4}$ standing | 1′:15 | Green at London . . | Aug. 2, 1899 |
| 1 flying | 1′:$22\frac{2}{5}$ | Major Taylor at Chicago | Aug. 3, 1899 |
| 1 standing | 1′:$38\frac{3}{5}$ | Chase at London . . | July, 26, 1900 |
| 2 ,, | 2′:$51\frac{2}{5}$ | Stinson at Brockton . | Oct. 24, 1900 |
| 3 ,, | 4′:18 | Elkes at Brockton . | Nov. 8, 1900 |
| 4 ,, | 5′:$44\frac{3}{5}$ | Elkes at Brockton . | Nov. 8, 1900 |

| 600 ,, | $22^h$:40:$05\frac{4}{5}$ | Walters at Paris . . | July 8–9, 1899 |

(J. P.*)

**Cyprus,** an island situated in the easternmost basin of the Mediterranean, in size only inferior to Sicily and Sardinia. It is nearly equally distant from the coast of Asia Minor to the north and from that of Syria to the east, lying between 34° 33′ and 35° 41′ N. lat., and 32° 20′ and 34° 35′ E. long. Its greatest length from west-south-west to east-north-east is about 140 miles, and its greatest breadth from north to south about 60 miles. The mean temperature is about 69° Fahr.; mean maximum, 78° Fahr.; mean minimum, 57° Fahr.; average rainfall for the last ten years, 19·16 inches. Where there are marshes there is malarial fever, but this is rarely of a severe type.

*Area and Population.*—In 1885 a trigonometrical survey and a map on the scale of 1 : 63360 were executed by Captain (now Lord) Kitchener, R.E., who made the area 3584 square miles. The population in 1881 was 186,173; in 1891, 209,286. The island is divided into six districts, which contain, besides their chief towns, 687 villages and 58 monasteries. LIMASOL (Gr. *Lemessos*), on the south coast, is the chief seat of the wine and carob trade. KYRENIA (Gr. *Kyreneia*), on the north coast, has a small harbour recently improved, and carries on some trade with the Cazamanian coast, which is plainly visible. Its castle, a virgin fortress, for it has never been captured, was built in the earliest years of the 13th century. For NICOSIA, FAMAGUSTA, LARNACA, and PAPHOS, see under those heads.

*Constitution and Government.*—Under a convention signed at Constantinople, 4th June 1878, Great Britain engaged to join the Sultan of Turkey in defending his Asiatic possessions (in certain contingencies) against Russia, and the Sultan, "in order to enable England to make necessary provision for executing her engagements," consented to assign the island of Cyprus to be occupied and administered by England. The British flag was hoisted on 12th June, and the conditions of the occupation were explained in an annex to the convention, dated 1st July. An Order in Council of 14th September, modified so far as related to legislation by another of 30th November, regulated the government of the island. The administration was placed in the hands of a High Commissioner with the usual powers of a Colonial Governor. Executive and Legislative Councils were established; and in each of the six districts into which, for administrative and legal purposes, the island was divided, a commissioner was appointed to represent the Government. The *Executive Council* consists of the High Commissioner, the Chief Secretary, the King's Advocate, the senior officer in charge of the troops, and the Receiver-General, with, as "additional" members, two Christians and one Mussulman. The *Legislative Council* consists of six non-elected members, being office-holders, and twelve elected members, three being chosen by the Moslems and nine by the non-Moslem inhabitants. British subjects and foreigners, who have resided five years in Cyprus, can exercise the franchise as well as Ottoman subjects. The qualification otherwise is the payment of any of the taxes classed as Vergi Taxes (see below). The courts in existence at the time of the occupation were superseded by the following, constituted by an Order in Council dated 30th November 1882:—(1) a supreme court of criminal and civil appeal; (2) six assize courts; (3) six district courts; (4) six magistrates' courts; and (5) village courts, at present ten in number. Actions are divided, according to the nationality of the defendant, into "Ottoman" and "Foreign"; in the latter, the president of the court alone exercises jurisdiction as a rule, so also in criminal cases against foreigners. The law administered is that contained in the Ottoman codes, modified by 337 ordinances passed by the Legislative Council.

*Religion.*—In 1891, 47,296 of the inhabitants were Moslems; nearly all the remaining 161,990 were Chris-

tians of the Orthodox Greek Church. The Mussulman religious courts, presided over by Cadis, are strictly confined to jurisdiction in religious cases affecting the Mahommedan population.

*Instruction.*—A general system of grants in aid of elementary schools was established in 1882. There are some 200 connected with the Greek Orthodox Church, receiving about £2730; about £650 is granted to some 70 elementary Moslem schools. Aid is also given to Armenian schools at Nicosia, a Maronite school at Kormakiti, a Moslem high school (maintained entirely by Government at a cost of about £200 a year), and a training college at Nicosia for teachers in the Orthodox Church schools, to which also £200 is granted annually. There are Greek high schools at Larnaca and Limasol. By a law of 1895 separate Boards of Education for Moslem and Greek Christian schools have been established, and in each district there are separate committees, presided over by the commissioner. The total enrolment is about 17,900—4400 Moslems and 13,500 Christians.

One hundred and twenty lepers are treated in a farm specially assigned to them. Eight weekly newspapers in Greek, and one in Turkish, are published in the island.

*Finance.*—The principal sources of revenue are:—

(1) Vergi taxes, or taxes on house and land property, and trade profits and incomes (not including salaries); (2) Military exemption tax, now payable by Moslems and Christians alike, but not by foreigners, of 2s. 6d. a head on males between 18 and 60 years of age; (3) Tithes. All tithes have been abolished, except those on cereals, carobs, silk cocoons, and, in the form of 10 per cent. *ad valorem* export duties, those on cotton, linseed, aniseed, and raisins (all other export duties and a fishing tax have been abolished); (4) Sheep, goat, and pig tax; (5) An excise on wine, spirits, and tobacco; (6) Import duties; (7) Stamps, court fees, royalties, licenses, &c.; (8) Salt monopoly.

There is a temporary tax of ½ per cent. on tithes and certain incomes to provide means for the destruction of the locusts. Foreigners are now liable to all the above taxes except the military exemption tax. The annual sum of £92,800, payable to Turkey as the average excess (according to the years 1873–78) of revenue over expenditure, but really appropriated to the interest on the British guaranteed loan of 1855, is a heavy burden. But if not lightened, taxation has at least been better apportioned.

*Production and Industry.*—Rock crystal and asbestos are still found in the district of Paphos. Gypsum is exported unburnt from the Carpas, and as plaster of Paris from Limasol and Larnaca. Statuary marble has been found on the slopes of Buffavento in the northern range. Excellent building stone exists throughout the island. The salt lakes of Larnaca and Limasol are practically inexhaustible. The most important species of the few trees that still remain in the island are the Aleppo pine, the Pinus laricio, Cypress, Cedar, Carob, Olive, and Quercus alnifolia. Recent additions are the Eucalyptus, Casuarina, Pinus pinea, and Ailanthus. Since 1878 some protection has been afforded to existing plantations, and some attempt made to extend their area; but the budget of the Forest Department is starved, and the progress made is slow. The soil is extremely fertile, and with a fair rainfall, say 13 inches, between November and April, yields magnificent crops, but the improvements in agriculture are scarcely satisfactory. The methods and appliances used are extremely primitive, and inveterate prejudice debars the average peasant from the use of new implements, of fresh seed, of manure; he cares nothing for the rotation of crops, or for the cleanliness of his land. A director of agriculture was appointed in 1896, and leaflets are issued pointing out improvements within the means of the villager, and how to deal with plant diseases and insect pests. The rehabilitation of the French vineyards has contributed almost fatally to the depreciation of the native wines, which are pure and strong, but not always palatable. The experiments made to improve the quality and to secure a European market have not, so far, proved remunerative. Very large sums have been expended on the destruction of locusts; they are now practically harmless, but live locusts and locusts' eggs are diligently collected every year. A committee exists "for the improvement of the breeds of Cyprus stock"; stallions of Arab blood have been imported, and prizes are offered for the best donkeys. Cattle, sheep, mules, and donkeys are sent in large numbers to Egypt. Cyprus mules have found favour in war in the Crimea, India, Uganda, Eritrea, and Egypt. Out of the £314,000 advanced under the Colonial Loans Act, 1899, £60,000 has been allotted for irrigation; and under the superintendence of an officer lent by the Government of Madras, two great works are in process of construction. The smaller includes a reservoir at Syncrasi (Famagusta D.), with a catchment of 27 square miles and a capacity of 70 million cubic feet. It reclaims 360 acres, and should irrigate 4320. The larger scheme includes three large reservoirs in the Mesaoria to hold up and temporarily store the flood waters of the Pedias and Yalias rivers. It is estimated that, at a cost of £50,000, 42,000 acres will be irrigated and 10,000 reclaimed. The net return is calculated at 5 per cent. on the cost of both schemes. Manufactures are unimportant.

*Commerce.*—During 1887–98 the annual value of imports and exports, as calculated for the financial year ending 31st March, fluctuated considerably. In 1887–88 the total imports were £356,375, and in 1887–89 the total exports averaged £205,781 (specie neglected). In 1899 the imports were—of goods, £289,962, and of specie, £27,799, a total of £317,761; and the exports were—of goods, £264,851, and of specie, £43,398, a total of £308,249. The most important items of imports in 1899 were manufactured cotton, £29,545; raw cotton, £18,498; tobacco, £21,961; woollens, £18,902; timber, £14,618; leather, £13,632; corn, &c. (mainly flour), £12,784; and of exports, carobs, £68,213; corn, &c. (mainly barley and wheat), £38,105; wine, £32,064; animals, £20,340; fruit (chiefly raisins), £19,829; silk cocoons, £14,708. The export of sponges reached 140 cwts.

*Shipping.*—In 1899, in the coasting trade, 2297 vessels (2080 sailing), of 146,465 tons entered, and 2358 (2141 sailing) of 145,462 tons cleared the ports; in the foreign trade 1149 vessels (932 sailing) of 258,454 tons entered, and 1144 (927 sailing) of 260,046, cleared.

*Internal Communications.*—(i.) ROADS: 488 miles of roads classed as "good" or fair "carriage roads" have been constructed between 1878–99, at a cost of £139,720. (ii.) POSTS AND TELEGRAPHS: There are 23 post offices, 18 rural mail sections, and 7 money order offices. In 1898–99, 268,670 internal letters were dealt with, 212,200 external, and 148,000 newspapers. The total cost of the postal service was £3094, leaving a surplus of £240. There are 9 telegraph offices. The Imperial Ottoman Telegraph Company has 67 miles of line, and a cable connecting the Carpas with Syria; the Eastern Telegraph Company has 170 miles of line, and a cable connecting Larnaca with Alexandria. In 1898–99 the former despatched 2650 messages, and the latter 17,750.

*Banking and Currency.*—The Imperial Ottoman Bank has branches at Larnaca, Nicosia, and Limasol. In 1882 the following coins were decreed legal currency: gold—sovereign, half-sovereign, Turkish lira, and French 20-franc piece; silver—florin, shilling, sixpence, and threepenny piece: limit of tender, £3; bronze—piastre (9 = 1s.), half-piastre, and quarter-piastre: limit of tender, 27 piastres. A law relating to weights and measures was passed in 1890. Those in use are the Turkish standards. The oke = 2·8 ℔ avoirdupois, and the donum = about ¼ acre.

AUTHORITIES.—*An Attempt at a Bibliography of Cyprus*, by C. D. COBHAM (4th ed., Nicosia, 1900), registers over 700 works which deal with Cyprus. No one full and comprehensive account of the island exists, though such is being compiled by Dr EUGEN OBERHUMMER, of Munich. The most interesting travels may be found under the names of FELIX FABER. *Evagatorium.* Stuttgart, 1843.—DE VILLAMONT. *Voyages.* Arras, 1598.—VAN KOOTWYCK. *Cotovici Itinerarium.* Antwerp, 1619.—R. COMTE DE MAS LATRIE published between 1852–61 one volume of *History* (1191–1291), and two of most precious documents in illustration of the reigns of the Lusignan kings.—FRA STEFANO LUSIGNANO, *Chorograffia di Cipro,* Bologna, 1573, and BP. STUBBS, *Two Lectures,* Oxford, 1878, are useful for the same period; and perhaps a score of contemporary pamphlets—the best of them by N. MARTINENGO, *Relatione di tutto il successo di Famagosta,* Venezia, 1572, and A. CALEPIO (in Lusignan's Chorograffia)—preserve the details of the famous sieges of Nicosia and Famagosta.—G. MARITI, *Viaggi,* Lucca, 1769, and CYPRIANOS, *History,* Venice, 1768, are the best authorities of Cyprus under Turkish rule. Mediæval tombs and their inscriptions are recorded and illustrated in T. J. CHAMBERLAYNE, *Lacrimæ Nicossienses,* Paris, 1894; and C. ENLART's charming and valuable volumes, *L'Art Gothique et la Renaissance en Chypre,* Paris, 1899, deal with mediæval architecture.—J. HACKETT treats exhaustively *The Church of Cyprus,* London, 1900. (C. D. C.)

## CYPRIOTE ARCHÆOLOGY.

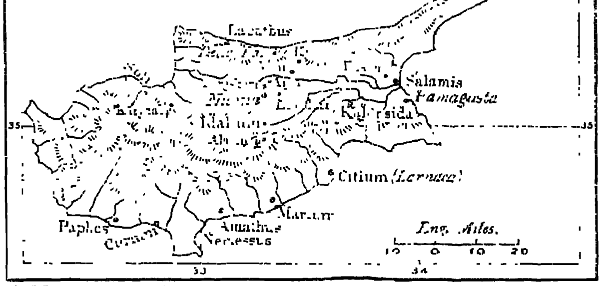
At the time when the article CYPRUS was written for the ninth edition of this Encyclopædia, little was known of the archæological history of the island. A few chance finds of vases, inscriptions, and coins; of a hoard of silver bowls at Dali (anc. *Idalium*)[1] in 1851; and of a bronze tablet with Phœnician and Cypriote bilingual inscriptions,[2] also at Dali, and about the same time, had raised questions of great interest as to the art and the language of the ancient inhabitants; Mr T. B. Sandwith, British Consul 1865–69, had laid the foundations of a sound knowledge of Cypriote pottery;[3] his successor Mr R. H. Lang (1870–72) had excavated a sanctuary of Aphrodite at Dali;[4] and at the time of writing[5] General Louis P. di Cesnola, American Consul 1872–76, was already exploring ancient sites, and opening tombs, in all parts of the island, though his results were not published till 1877.[6] But though his vast collection, now in the Metropolitan Museum of New York, remains the largest series of Cypriote antiquities in the world, the accounts which have been given of its origin are so inadequate, and have provoked so much controversy,[7] that its scientific value is small, and a large part of subsequent excavation has necessarily been directed to solve the problems suggested by its practically isolated specimens. From 1876 to 1878 Major Alexander P. di Cesnola continued his brother's work, but the large collection which he exhibited in London in 1880 was dispersed soon afterwards.[8]

On the British occupation of Cyprus in 1878, the Ottoman Law of 1874 in regard to antiquities was retained in force. Excavation is permitted under Government supervision, and the finds are apportioned in thirds, between the excavator, the landowner (who is usually bought out by the former), and the Government. The Government thirds lie neglected in a "Cyprus Museum" maintained at Nicosia by voluntary subscription. There is no staff, and no effective supervision of ancient sites or monuments. A catalogue of the collections was published by the Oxford University Press in 1899.[9] Since 1878 more than seventy distinct excavations have been made in Cyprus, of which the following are the most important.

In 1879 the British Government used the acropolis of *Citium* (Larnaca) to fill up the ancient harbour; and from the destruction a few Phœnician inscriptions, and a proto-Ionic capital, were saved. In 1882 tombs were opened by Mr G. Hake at *Salamis* and *Curium* for the South Kensington Museum, but no scientific record was made. In 1883 the Cyprus Museum was founded by private enterprise, and on its behalf Mr Max Ohnefalsch-Richter, who had already made trial diggings for Sir Charles Newton and the British Museum, excavated sanctuaries at Vóni and Kythréa (*Chytri*), and opened tombs on some other sites.[10]

In 1885 Dr F. Dümmler opened tombs at Dali, Alámbra, and elsewhere, and laid the foundations of knowledge of the Bronze Age and Early Iron Age;[11] and Mr Richter, on behalf of officials and private individuals, excavated parts of Frángissa (*Tamassus*), Episkopì, and Dali.[12]

In the same year 1885, and in 1886, a syndicate opened many tombs at Póli-tis-Khrýsochou (*Marium, Arsinoe*), and sold the contents by auction in Paris. From Mr Richter's notes of this excavation, Dr P. Herrmann



*B. V. Darbishire & O. J. R. How* *Oxford, 1901*

CYPRUS (EXCAVATION SITES).

compiled the first scientific account of Græco-Phœnician and Hellenistic Cyprus.[13] In 1886 also, M. le Vicomte E. de Castillon de St Victor opened rich Græco-Phœnician tombs at Episkopì, the contents of which are in the Louvre.[14]

The successes of 1885–86 led to the foundation of the Cyprus Exploration Fund, on behalf of which (1) in 1888 the sanctuary of Aphrodite at *Paphos* (Kouklia) was excavated by Messrs E. Gardner, M. R. James, D. G. Hogarth, and R. Elsey Smith;[15] (2) in 1889–90 more tombs were opened at Poli by Messrs J. A. R. Munro and H. A. Tubbs;[16] (3) in 1890–91 extensive trials were

made at *Salamis*, by the same;[1] (4) minor sites were examined at Leondári Vounò (1888),[2] Amargetti (1888),[3] and Limniti (1889);[4] (5) in 1888 Mr Hogarth made a surface-survey of the Karpass promontory;[5] and finally, (6) in 1894, the balance was expended by Mr J. L. Myres in a series of trials, to settle special points, at Agia Paraskevì, Kalopsída, and Larnaca.[6] In 1894 also, Dr Richter excavated round *Idalium* and *Tamassus* for the Prussian Government: the results, unpublished up to 1902, are in the Berlin Museum.[7] Finally, a legacy from Miss Emma T. Turner enabled the British Museum to open numerous tombs, by contract, of the Græco-Phœnician Age, in 1894, at Palæò-Lemessò (*Amathus*); and of the Mycenæan Age, in 1894–95 at Episkopì, in 1895–96 at Enkomi (near *Salamis*), and in 1897–99 on small sites between Larnaca and Limasol.[8] Many important sites remain still unexplored, and many problems unsolved; but the outline of Cypriote archæology which follows may give some idea of the conclusions established hitherto.

The Stone Age has left but few traces in Cyprus; no sites have been found, and even single implements are very rare. The "megalithic" monuments of Agia Phaneroméni and Halat Sultàn Teké, near Larnaca, may perhaps be dolmens of the Palestinian type; the vaulted chamber of Agia Katrína, near Enkomi, may be Mycenæan or later; the perforated monoliths at Ktima belong to oil-presses of uncertain date.

The Bronze Age, on the other hand, is of peculiar importance in an area which, like Cyprus, was one of the chief early sources of copper. It has been carefully studied both on settlement sites at Leondári Vounò and Kalopsída, and in tombs in more than thirty places, notably at Agia Paraskevì, Psemmatisméno, Alámbra, Episkopì, and Enkomi. Cypriote Bronze Age culture falls into three stages. In the first, the implements are rather of copper than of bronze, tin being absent or in small quantities (2 to 3 per cent.); the pottery, of gourd-like and often fantastic forms, is all hand-made, with a red burnished surface, with simple geometrical ornaments incised. Zoomorphic art is very rare, and imported objects are unknown. In the second stage, implements of true bronze (9 to 10 per cent. tin) become common; painted pottery appears alongside the red-ware, and foreign imports occur, such as Egyptian blue-glazed beads (xii.–xiii. dynasty: 2500–2000 B.C.) and Asiatic cylindrical seals (one of Sargon I. +2000 B.C.). In the third stage, intercourse with Palestine and Egypt, following the conquests of Thothmes III. (*c.* 1500 B.C.), brought over new fabrics of pottery, which were freely copied; and Ægean colonists introduced the Mycenæan culture and art, which rapidly dominated the primitive native industries: new types of weapons, and wheel-made pottery appear; gold and ivory become abundant, and glass and enamels are known. The magnificent tombs from Enkomi and Episkopì (in the British Museum) illustrate the wealth and advancement of Cyprus at this time.[9]

The early Iron Age which succeeds is a period of obscurity and relapse. Iron, which occurs rarely, and for ornaments, in some of the tombs at Enkomi suddenly superseded bronze for tools and weapons, and its introduction was accompanied, as in the Ægean, by economic, and probably by political changes, which broke up the high civilization of the Mycenæan colonies, and brought about a return to poverty, isolation, and comparative barbarism. Gold, and even silver, become rare; foreign imports almost cease; engraved cylinders are replaced by conical or pyramidal seals like those of Asia Minor, and dress-pins by brooches (*fibulæ*) like those of Greece; representative art languishes (except a few childish attempts to model in clay), and the decorative art becomes once more purely geometrical in character.

But while Mycenæan traditions lingered in Cyprus after their extinction in the Ægean, new Oriental influences from the Syrian coast were felt there earlier than farther west. Two lines of foreign tradition may be distinguished, originating in Egypt and Assyria respectively. Of these, the former predominates somewhat earlier than the latter, a historical date for which is given by the Assyrian conquest of Cyprus in 704 B.C. The effects are best seen in sculpture and in metal-work, though it remains doubtful whether the best examples of the latter were made in Cyprus or on the mainland. Among the great series of engraved silver bowls, some examples show almost unmixed imitation of Egyptian types; in others, Assyrian types are introduced among the Egyptian in senseless confusion; while in others both classes are merged in a mixed art which betrays a return to naturalism, and a new sense of style, and from its intermediate position between the art of Phœnicia and its colonies, and the earliest art of Hellenic Greece, has been called *Græco-Phœnician*. The same succession of styles is represented in sculpture by the votive statues from the sanctuaries of Aphrodite at Dali and of Apollo at Vóni and Frángissa; by the elaborately painted terra-cottas from the "Toumba" site at Salamis; and by magnificent examples in the Cesnola collection. Gem-engraving and pottery-painting follow very similar lines; the latter, however, with greater naïveté of treatment, and closer adherence to Mycenæan traditions.

Meanwhile, Ægean influences, which had been predominant in the Mycenæan Age, and had never wholly ceased, grew stronger as Hellenic culture matured, and slowly repelled Phœnician Orientalism. Imported vases of "Dipylon," "Proto-Corinthian," and "Rhodian" fabric (though not of orientalizing "Corinthian") occur rarely, and were imitated by the native potters, and early in the 6th century the influence of Ionia, and still more of Naucratis, becomes perceptible in imports, in ceramic, and in sculpture. Finally, from the later 6th century, and the period of "black-figured" vases onwards, a rapidly increasing mass of Attic imports (chiefly vases) brings Cyprus at last into full contact with Hellenism. Unable, however, to rival, or fully to acquire, this higher culture, native art and industry languished and became extinct even before the Ptolemaic conquest (295 B.C.), except, perhaps, in Citium, the headquarters of Phœnician influence in the island. A rare and beautiful class of terra-cottas like those of Myrina and Tanagra *may* be of Cypriote fabric, but their style is wholly of the Ægean. The Greek colonists in Cyprus traced their origin, at Curium, from Argos;[10] at Lapathus from Laconia;[11] at Paphos from Arcadia;[12] at Salamis from the Attic Salamis;[13] and at Soli also from Attica.[14] The settlements at Paphos and Salamis, and probably also at Curium, were believed to date from the period of the Trojan War; the name of Teucer, the legendary founder of Salamis, probably represents a memory of the piratical Tikkara who harried the Egyptian coast under Rameses III.; and the discovery of Mycenæan settlements at Curium and Salamis, and of traces of sub-Mycenæan occupation at Paphos and Lapathus, goes far to confirm the belief that the legends have a historical basis. The Greek dialect of Cyprus points in the same direction; it shows marked resemblances to that of Arcadia,[15] and forms with it a "South Achæan" or "South Æolic" group related to the northern Æolic of Thessaly and other parts of north and central Greece. No Greek alphabet was used in Cyprus, except by visitors,[16] until the 4th century, and the numerous inscriptions of earlier date than this are written in a peculiar and elaborate syllabary[17] which can be traced in use in late Mycenæan times,[18] and is apparently related to the linear and pictographic scripts of Crete and the South Ægean.[19] In the Phœnician centres, Citium and Idalium, a Semitic dialect and the Phœnician alphabet were in use from the 8th century at least[20]; and a cuneiform inscription recording the conquest of the island by Sargon II. has been found at Larnaca.[21]

The coins of the Greek dynasts and autonomous towns are struck on a variable standard, with a stater of 170–180 grs.[22]

For Ptolemaic (Hellenistic) Cyprus the evidence is most inadequate. Excavation in the great sanctuaries at Paphos and Idalium, and in the public buildings of Salamis, which were all wholly remodelled during this period, have produced but few works of art; and the sculpture from local shrines at Voni and Vitsada, and the frescoed tombstones from Amathus, only show how inadquately the Cypriote copied debased Hellenistic models.

For the Roman period there is abundant evidence from the sites of Salamis and Paphos, and from tombs everywhere; but little that

is characteristic or noteworthy; little attention has been paid to the sequence of style.

Of the Byzantine period little remains but the ruins of the castles of St Hilarion, Buffavento, and Kantára,[1] a magnificent series of gold ornaments[2] and some silver plate,[3] found near Kerynia in 1883 and 1897 respectively. Christian tombs usually contain nothing of value.

The Frank conquest is represented by the "Crusaders' tower" at Kolossi, and the church of St Nicholas at Nicosia; and, later, by masterpieces of a French Gothic style, such as the church (mosque) of St Sophia, and other churches at Nicosia; the cathedral (mosque) and others at Famagusta, and the monastery of Bella Pais; as well as by domestic architecture at Nicosia and elsewhere, and by a rich series of inscribed tombstones in the churches. The elaborate wood-carvings of the church at Aschelia[4] belong to the 15th century, and the "miraculous" picture at the monastery of Kykkou apparently to the 16th. The architecture of the Renaissance is illustrated by fortifications and remains of public buildings (now being quarried away) at Famagusta, by walls, gates, and domestic buildings at Nicosia, and by forts at Kerynia, Limasol, and elsewhere.

The Turks and English have added little, and destroyed much, converting churches into mosques and grain-stores, and quarrying the buildings and walls of Famagusta. There is an iron bridge over the Pedias river, and a harbour at Famagusta has been proposed. (J. L. M.)

**Cyprus, Church of.**—The Church of Cyprus is in communion and in doctrinal agreement with the other Orthodox Churches of the East (see ORTHODOX EASTERN CHURCH), but is independent (αὐτοκέφαλος) and subject to no patriarch. This position it has always claimed (see, however, W. Bright, *Notes on the Canons*, on Ephesus 8). At any rate, its independence "by ancient custom" was recognized, as against the claims of the patriarch of Antioch, by the Council of Ephesus, A.D. 431, by an edict of the Emperor Zeno (to whom the church had sent a cogent argument on its own behalf, the alleged body of its reputed founder St Barnabas, then just discovered at Salamis), and by the Trullan Council in 692. Attempts have been made subsequently by the patriarchs of Antioch to claim authority over it, the last as recently as 1600; but they came to nothing. And excepting for the period during which Cyprus was in the hands of the Lusignans and the Venetian Republic (1193–1571), the Church has never lost its independence. It receives the holy ointment (μῦρον) from without, till 1860 from Antioch and subsequently from Constantinople, but this is a matter of courtesy and not of right. Of old there were some twenty sees in the island. The bishop of the capital, Salamis or Constantia, was constituted metropolitan by Zeno, with the title "archbishop of all Cyprus," enlarged subsequently into "archbishop of Justiniana Nova and of all Cyprus," after an enforced expatriation to Justinianopolis in 688. Zeno also gave him the unique privileges of wearing and signing his name in the imperial purple, &c., which are still preserved. A Latin hierarchy was set up in 1196 (an archbishop at Nicosia with suffragans at Limasol, Paphos, and Famagusta), and the Greek bishops were made to minister to their flocks in subjection to it. The sees were forcibly reduced to four, the archbishopric was ostensibly abolished, and the bishops were compelled to do homage and swear fealty to the Latin Church. This bondage ceased at the conquest of the island by the Turks: the Latin hierarchy disappeared (the cathedral at Nicosia is now used as a mosque), and the native church emerged into comparative freedom. In 1821, it is true, all the bishops and many of their flock were put to death by way of discouraging sympathies with the Greeks; but successors were soon consecrated, by bishops sent from Antioch at the request of the patriarch of Constantinople, and on the whole the Church has prospered. The bishops-elect required the *berat* of the Sultan; but having received this, they enjoyed no little civil importance. Since 1878 the *berat* has not been given, and the bishops are less influential. The suppressed sees have never been restored, but the four which survive (now known as Nicosia, Paphos, Kition, and Kyrenia) are of metropolitan rank, so that the archbishop, whose headquarters, first at Salamis, then at Famagusta, are now at Nicosia, is a primate amongst metropolitans. There are several monasteries dating from the 11th century and onwards; also an archiepiscopal school at Nicosia, founded in 1812 and raised to the status of a "gymnasion" in 1893; and a high school for girls. But there is no theological seminary, and the ignorance of the clergy is great. Still, there are signs of progress, especially since the island passed into British hands; and if the great revenues of the Church can be redistributed and better administered, excellent results will doubtless follow.

**Cytology (Vegetable).**—Remarkable progress has been made of late years in our knowledge of minute cell structure, or Cytology, around which so much of the biological research of the present time revolves, and upon which the ultimate solution of important problems in physiology depends. This has been due largely to the application of the ribbon section-cutting microtome to histological research, to more refined methods of fixing, staining, and mounting, and to the immense improvements made in optical instruments. Among the more important subjects in which progress has been made are the minute structure of protoplasm; the phenomena of nuclear division; the structure and development of the sexual cells and germ-nuclei; the phenomena of fertilization; the structure and development of the cell-wall, starch-grains, and plastids; the protoplasmic connexions between the cells; and the structure and development of sieve-tubes and laticiferous tissue. But although much has been accomplished, we are still far from a complete understanding of minute cell-structure, and, unfortunately, the brilliant results which have been obtained by the investigation of dead stained tissues have so dominated the attention of students during this period that the living cell has been neglected, and doubt has, in consequence, been cast upon some of the results obtained. It is probable, therefore, that in the future any substantial advance in our knowledge will come, not from the exclusive study either of dead or living cells, but from a judicious correlation of observations upon both.

The contents of a living cell are collectively termed protoplasm. This consists of a semi-fluid granular substance, called the cytoplasm, one or more nuclei, and sometimes centrospheres or centrosomes, and plastids. Cells from different parts of a plant differ very much in their cell-contents. Young cells are often full of cytoplasm; old cells generally contain a large vacuole or vacuoles, and may have only a thin, almost invisible, layer of cytoplasm on their walls. Others contain chlorophyll-grains or chromatophores, starch-grains, or oil-globules. Very little is known of the finer structure of the cytoplasm of a vegetable cell. When observed under the microscope it is usually seen to consist of a homogeneous substance containing numerous granules of various sizes, and vacuoles, which are probably full of a watery

sap. It is sometimes differentiated into a clearer outer layer, of hyaloplasm, commonly called the ectoplasm, and an inner granular endoplasm. In some cases it shows, when submitted to a careful examination under the highest powers of the microscope, and especially when treated with reagents of various kinds, traces of a more or less definite structure which is sometimes very complicated. This exhibits itself in the form of a meshwork which consists of a clear homogeneous substance containing numerous minute bodies known as *microsomes*, the spaces being filled by a more fluid *ground-substance.* This structure, which is visible both in living cells and in cells treated by reagents, has been interpreted by many observers as representing a network of threads embedded in a homogeneous ground-substance. Bütschli, on the other hand, interprets it as an extremely finely vacuolated foam-structure or emulsion, comparable to that which is observed when small drops of a mixture of finely powdered potash and oil are placed in water, the vacuoles or alveoli being spaces filled with liquid, the more solid portion representing the mesh-work in which the microsomes are placed. According to Strasburger, the cytoplasm consists of *trophoplasm*, or nutritive plasm, and *kinoplasm*, which is concerned in the division of the cell. The former is of alveolar, the latter of fibrillar, nature. The structure of the protoplasm as revealed by the action of reagents is regarded with scepticism by many observers, and it has been shown, by Fischer especially, that some of the appearances observed in dead cells can be produced artificially by treating albumen and other substances of a similar nature with various reagents. But whilst due weight must be attached to such observations, it would not be wise to push them too far. The objects which are actually visible in the living cell are reproduced with striking fidelity in the fixed and hardened cell, and one might expect that their finer structure would also be to some extent preserved.

Living protoplasm is alkaline or neutral, and, so far as is known at present, is a mixture of complicated chemical compounds. By the gross analysis of simple organisms which consist mainly of protoplasm, it has been found that there are two main groups of compounds, in one of which phosphorus is present, in the other not. The phosphorus is especially abundant in the nucleus, where it enters into the composition of that important substance known as *nuclein.* It may also be present in smaller quantities in other parts of the cell. By means of a simple micro-chemical test Macallum finds that it occurs in the chromatin of all nuclei, in nucleoli, and in pyrenoids; and that it is present in small quantities in cytoplasm and chromatophores, in the central body (nucleus?) of the Cyanophyceæ and in Yeast, where it is sometimes located in a definite organ of the cell which is commonly regarded as of a nuclear nature.

***Chromatophores.***

The chromatophores or plastids are protoplasmic structures, denser than the cytoplasm, and easily distinguishable from it by their colour or greater refractive power. They are spherical, oval, fusiform, or rod-like, and are always found in the cytoplasm, never in the cell-sap. They appear to be permanent organs of the cell, and are transmitted from one cell to another by division. In young cells the chromatophores are small, colourless, highly refractive bodies, principally located around the nucleus. As the cell grows they may become converted into *leucoplasts* (starch-formers), *chloroplasts* (chlorophyll-bodies), or *chromoplasts* (colour-bodies). And all three structures may be converted one into the other (Schimper). The chloroplasts are generally distinguished by their green colour, which is due to the presence of chlorophyll; but in many Algæ this is masked by another colouring matter—*Phycoerythrin* in the Florideæ, *Phycophæin* in the Phæophyceæ, and *Phycocyanin* in the Cyanophyceæ. These substances can, however, be dissolved out in water, and the green colouring matter of the choloroplast then becomes visible. Its structure is difficult to make out, but the views put forward by various observers lead to the conclusion that the chloroplast consists of two parts, a colourless ground substance, and a green colouring matter, which is contained either in the form of fibrils, or in more or less regular spherical masses, in the colourless ground-mass. The chloroplasts increase in number by division, which takes place in higher plants when they have attained a certain size, independent of the division of the cell. In *Spirogyra* and allied forms the chloroplast grows as the cell grows, and only divides when this divides. The division in all cases takes place by constriction, or by a simultaneous splitting along an equatorial plane. In the chromatophores of many Algæ and in the Liverwort *Anthoceros* there are present homogeneous, highly refractive, crystal-like bodies, called *pyrenoids* or starch-centres, which are composed of proteid substances and surrounded by an envelope of starch-grains. In *Spirogyra* the pyrenoids are distinctly connected by cytoplasmic strands to the central mass of cytoplasm, which surrounds the nucleus, and according to some observers, they increase exclusively by division, followed by a splitting of the cytoplasmic strands. Those chromatophores which remain colourless, and serve simply as starch-formers in parts of the plant not exposed to the light, are called leucoplasts or amyloplasts. They are composed of a homogeneous proteid substance, and often contain albuminoid or proteid crystals of the same kind as those which form the pyrenoid. If exposed to light they may become converted into chloroplasts. The formation of starch may take place in any part of the leucoplast. When formed inside it, the starch-grains exhibit a concentric stratification; when formed externally in the outer layers, the stratification is excentric, and the hilum occurs on that side farthest removed from the leucoplast. As the starch-grains grow, the leucoplasts gradually disappear. Chromoplasts are the yellow, orange, or red colour-bodies found in some flowers and fruits. They arise either from the leucoplasts or chloroplasts. The fundamental substance or stroma is colourless and homogeneous. The colour is due to the presence of xanthophyll, or carotin, or both. The colouring matters are not dissolved in the stroma of the chromoplast, but exist as amorphous granules, with or without the presence of a protein crystal, or in the form of fine crystalline needles, frequently curved and sometimes present in large numbers, which are grouped together in various ways in bundles, and give the plastids their fusiform or triangular crystalline shape. Such crystalline plastids occur in many fruits and flowers (*e.g.*, *Tamus communis*, *Asparagus*, *Lonicera*, berries of Solaneæ, flowers of *Cacalia coccinea*, *Tropæolum*, bracts of *Strelitzia*, &c.), and in the root of the carrot. In some cases the plastid disappears and the crystalline pigment only is left. In the red variety of *Cucurbita pepo* these crystals may consist of rods, thin plates, flat ribbons, or spirals. Starch grains may often be seen in contact with the pigment crystals. The crystalline form appears to be due entirely to the carotin, which can be artificially crystallized from an alcohol or ether solution. In addition to the plastids, there are found in some plant-cells, *e.g.*, in the epidermal cells of the leaf of species of *Vanilla* (Wakker), and in the epidermis of different parts of the flower of *Funkia*, *Ornithogalum*, &c. (Zimmermann), highly refractive bodies of globular form, *elaioplasts*, which consist of a granular protein ground-

substance containing drops of oil. They are stained deep red in dilute solution of alkannin. There appears to be one in each cell, and in *Orithogalum umbellatum* it occurs at one of the poles of the elongated nucleus. An oily substance in the form of drops may also occur in chromatophores, and, in the Hepaticæ, oil-bodies are found which may have some relation to elaioplasts. Although no special oil-forming plastid has been observed, it appears from these observations that oil may sometimes be formed by special structures, or may accumulate in them (Pfeffer). The eye-spot which is found in motile cells of the Algæ, *Protococcus*, *Euglena*, &c., may also have something in common with the elaioplast. In *Euglena* it consists of a protoplasmic substance, in which are embedded numerous spherical or irregular drops of a red oily substance. The red colouring matter turns blue in concentrated sulphuric acid, and is probably related to the red colouring matter of chromoplasts. The eye-spot appears to be concerned in some way with the response to the light-stimulus which is exhibited by cells containing it.

It is highly probable that starch is only produced as the result of the activity of chromatophores, either in connexion with chromoplasts, chloroplasts, or leucoplasts. Starch exists, in the majority of cases, in the form of grains, which are composed of stratified layers arranged around a nucleus or hilum. The stratification, which may be concentric or excentric, appears to be due to a difference in density of the various layers. The outer layers are denser than the inner, the density decreasing more or less uniformly from the outside layers to the centre or hilum. The outermost, newly-formed layer is composed of a more homogeneous, denser substance than the inner one, and can be distinguished in all starch-grains that are in process of development. The separate layers of the starch-grain are deposited on it by the activity of the chromatophore, and according to Meyer the grain is always surrounded by a thin layer of the chromatophore which completely separates it from the cytoplasm. The layers appear to be made up of elements which are arranged radially. These are, according to Meyer, acicular crystals, which he calls *trichites*. The starch grain may thus be regarded as a crystalline structure of the nature of a sphere-crystal, as has been suggested by many observers.

***Nucleus.***

The nucleus appears to be an essential constituent of the cell. Its presence has been demonstrated in all plants with the exception of the Cyanophyceæ and Bacteria, and even here structures have been observed which resemble nuclei in some of their characteristics, and are thought to be such by some observers. The nucleus is generally regarded as a controlling centre of cell-activity, upon which the growth and development of the cell in large measure depends, and as the agent by which the transmission of specific qualities from one generation to another is brought about. If it is absent, the cell loses its power of assimilation and growth, and soon dies. Haberlandt has shown that in plant cells, when any new formation of membrane is to take place in a given spot, the nucleus is found in its immediate vicinity; and Klebs found that only that portion of the protoplasm of a cell which contains the nucleus is capable of forming a cell-wall; whilst Townsend has further shown that if the non-nucleated mass is connected by strands of protoplasm to the nucleated mass, either of the same cell or of a neighbouring cell, it retains the power of forming a cell-membrane.

The nucleus consists of an irregular network of threads surrounded by a nuclear membrane, which separates it from the cytoplasm. The nuclear cavity in which the network is placed contains a more or less fluid nuclear sap, and in the majority of plant-nuclei, but not in all, one or more spherical or slightly irregular bodies, the *nucleoli*. In the living condition the nucleus appears granular, and the thread structure is in most cases invisible, but the nucleolus is sometimes distinguishable by its more refractive appearance. The structure of the nuclear thread can only be made out by the use of reagents. It consists of a ground-substance called *Linin*, which is only slightly stained by the ordinary nuclear stains, and, embedded in it, numerous grains of a substance called *Chromatin*, having a strong affinity for stains. These chromatin-granules are looked upon by some observers as independent morphological units, the *ids* of Weismann. The staining reactions of the various parts of the nucleus depend to some extent upon their chemical constitution, especially with regard to the amount of phosphorus they contain. The chromatin is practically identical with nuclein, a complex albuminoid compound containing about 3 per cent. of phosphorus. This has a strong attraction for basic aniline dyes, and can usually be distinguished from those parts of the cell which are more easily coloured by acid anilines. But the staining reactions of nuclei may vary at different stages of their development; and it is probable that there is no method of staining which differentiates with certainty the various morphological constituents of the nucleus.

The formation of new cells by division is, in the case of uninucleate cells, preceded by or accompanied by the division of the nucleus. In multinucleate cells the division of the nucleus is independent of the division of the cell. Nuclear division may be indirect or direct, that is to say it may either be accompanied by a series of complicated changes in the nuclear structures called *mitosis* or *karyokinesis*, or it may take place by simple direct division, *amitosis*, or fragmentation. Direct division is a much less common phenomenon than was formerly supposed to be the case. It occurs most frequently in old cells, or in cells which are placed under abnormal conditions. It may also take place where rapid proliferation of the cell is going on, as in the budding of the Yeast plant. It takes place in the internodal cells of Characeæ; in the old internodal cells of *Tradescantia*; and in various other cells which have lost their power of division. It has been shown that, in cells of *Spirogyra* placed under special conditions, amitotic division can be induced, and that normal mitosis is resumed when they are placed again under normal conditions. Amitosis is probably connected by a series of intermediate gradations with karyokinesis.

In indirect nuclear division the nucleus undergoes a series of complicated changes, which result in an equal division of the chromatic substance between the two daughter nuclei. Four stages can be recognized. (1) *Prophase.*—The nucleus increases in size; the network disappears, and a much convoluted thread takes its place (Fig. 1, B). The chromatin substance increases in amount; the thread stains more deeply, and in most cases, presents a homogeneous appearance. This is commonly called the spirem-figure. The chromatin thread next becomes shorter and thicker, the nucleoli begin to disappear, and the thread breaks up into a number of segments—*chromosomes*—which vary in number in different species, but are fairly constant in the same species (Fig. 1, C, D). Coincident with these changes the nuclear membrane disappears and a spindle-shaped or barrel-shaped group of threads makes its appearance in the midst of the chromosomes, the longitudinal axis of which is at right angles to the plane of the division (Fig. 1, F). At each pole of this spindle figure there often occur fibres radiating in all directions into the cytoplasm, and sometimes a minute granular body, the *centrosome*, is also found there. (2) *Metaphase.*—The chromosomes pass to the equator of the spindle and become attached to the spindle-fibres in such a way that they form a radiating star-shaped

figure—*Aster*—when seen from the pole of the spindle. This is called the nuclear plate (Fig. 1, E, F, G, H). As they pass into this position they undergo a longitudinal splitting by which the chromatin in each chromosome becomes divided into equal halves. (3) *Anaphase.*—The longitudinal division of the chromosomes is completed by the time they have taken up their position in the nuclear plate, and the halves of the chromosomes then begin to move along the spindle-fibres to opposite poles of the spindle (Fig. 1, I, J). Many observers hold the view that the chromosomes are pulled apart by the contraction of the fibres to which they are attached. (4) *Telophase.*—When they reach the poles the chromosomes group themselves again in the form of stars—*Diaster*—with spindle-fibres extending between them (Fig. 1, K). The chromosomes then fuse together again to form a single thread (Fig. 1, L), a nucleolus appears, a nuclear membrane is formed, and daughter nuclei are thus constituted which possess the same structure and staining reactions as the mother nucleus. When this nuclear division is followed by cell-division, a cell-wall is formed between the two daughter nuclei. The spindle-fibres which extend between the daughter nuclei increase in number and extend laterally until they touch the cell-walls. They then thicken in the middle, and form a layer of granules across the cell—the cell-plate. These then disappear and the new cell-wall appears in their place. In the lower plants the new cell-wall may be formed as an outgrowth on the old one (*Spirogyra*, &c.), or it may be formed directly in the cytoplasm.

The spindle figure is probably the expression of forces which are set up in the cell for the purpose of causing the separation of the daughter chromosomes. It arises partly from the cytoplasm, partly from the nucleus, or it may be derived entirely from the nucleus—intranuclear spindle—as occurs in many of the lower plants (Fungi, &c.). The formation of the spindle begins in the prophases of division. A layer of delicate filamentous cytoplasm—kinoplasm—may collect around the nucleus, or at its poles, out of which the spindle is formed. As division proceeds, the filamentous nature of this cytoplasm becomes more prominent, and the threads begin either to converge towards the poles of the nucleus, to form a bipolar spindle, or may converge towards, or radiate from, several different points, to form a multipolar spindle. The wall of the nucleus breaks down, and the cytoplasmic spindle-fibres become mixed with those derived from the nuclear network. The formation of the spindle differs in details in different plants.

The longitudinal splitting of the chromosomes appears to take place in order to ensure that one-half of each chromatin unit—*id*—shall be distributed to each daughter nucleus. The longitudinal division of the linin thread is in fact probably initiated by the division of these chromatin granules, which are arranged in a single row along the thread. In many cases the granular nature of the chromosome is masked by the shortening of the thread and the absorption of additional chromatin substances during the various stages of the prophase, so that the chromosome appears to be a homogeneous structure. In other cases the longitudinal splitting takes place before the chromosome stage, in which case two rows of granules are visible on the linin thread at an early stage, and the shortening and thickening do not take place until the daughter chromosomes have become visible as separate threads. This phenomenon is especially prominent in the nuclear divisions which lead to the formation of the sexual cells. Here certain other features also present themselves which are not observed in the vegetative nuclei, the most important being the reduction in the number of chromosomes—to one-half. This takes place in the spore mother-cells of all those Vascular Cryptogams and Phanerogams which have been investigated, and is probably of general occurrence. We know very little of the phenomenon as it takes place in the lower plants, but in *Fucus* it occurs in the oogonial stage, so that the cells of the vegetative plant have the full number. Inasmuch as the essential feature of fertilization is the fusion of two nuclei, it is evident that unless this reduction took place the number of chromosomes would be doubled at each generation. In the higher plants this reduced number is found in all the cells of the gametophyte, the full

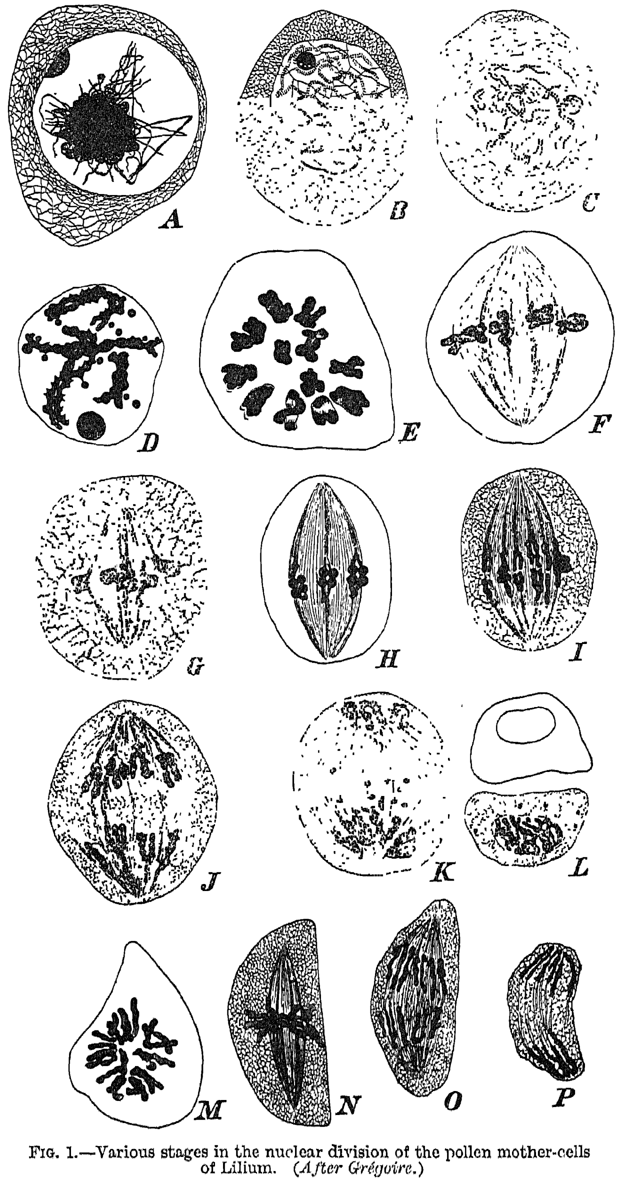

Fig. 1.—Various stages in the nuclear division of the pollen mother-cells of Lilium. (*After Grégoire.*)

number in those of the sporophyte. The reduction is brought about simply by the segmentation of the spirem thread into half the number of segments instead of the normal number; but there is no diminution in the actual amount of nuclear substance. During the second division, however, it has been stated that a qualitative reduction is brought about by the transverse division of the chromosomes, and that different chromatin granules, or ids, are thus distributed to the daughter nuclei. This has an important bearing upon the supposed function of the ids as the bearers of hereditary qualities in fertilization; but the most recent investigations seem to show that, so far as

plants are concerned, such transverse divisions do not take place. In the process of division of a spore mother-cell the spirem thread is divided longitudinally before the segmentation occurs (Fig. 1, B), and this is preceded by a peculiar contraction of the thread around the nucleolus which has been termed *synapsis* (Fig. 1, A). It has been suggested that this may be connected with the early splitting of the thread, but some observers regard it as a contraction due to reagents. The segments of each chromosome are usually twisted upon each other and may be much contorted (Fig. 1, C, D). Soon after the segmentation the chromosomes begin to shorten and thicken, and another peculiar phenomenon is then observed—each longitudinal half of the chromosome exhibits a double row of dots instead of a single row, probably due to a second division of the chromatin granules. This is not, however, accompanied by a longitudinal fission of the linin segment, and the granules are soon obscured by the continued shortening and thickening of the chromosome, which finally becomes homogeneous (Fig. 1, E). The longitudinal segments of the chromosome become more or less fused together, especially at the ends, by which variously shaped figures are produced of greater or less regularity (Fig. 1, E). The chromosomes now become attached to the spindle-fibres (Fig. 1, F, G), and as the daughter chromosomes become pulled asunder they often appear more or less V-shaped, so that each pair appears as a closed ring of irregular shape, the ends of the V's being in contact thus—<> (Fig. 1, H, I, J, K.). This V has been variously interpreted. Some observers consider that it is due to bending, others to the early longitudinal splitting, of the daughter chromosomes, the segments of which remaining connected together at one end, produce a V-shaped figure. From the recent observations of Strasburger it appears probable that the latter interpretation is the correct one in most cases, and that the former only occurs exceptionally. The form of division which is thus characterized by the early longitudinal fission of the chromosomes and the formation of more or less regular rings is called the *heterotype* division. In the one case, therefore, this ring is formed by a single longitudinal fission and subsequent bending of the two halves of the chromosome; in the other, by two longitudinal fissions at right angles to one another. In either case the first division of the germ-nucleus in which the reduced number of chromosomes appears, results in an equal division of the chromatin granules or ids to each daughter nucleus, just as in the vegetative nuclei. But now comes the important question. Is the division which next takes place in the daughter nuclei of this nature, or is it effected in such a manner as to produce a qualitative separation of the chromatin? In other words, is the division of the chromosomes of the daughter nuclei longtitudinal or transverse? Some observers contend that where the V shape is produced by a bending of the chromosome, the division is accomplished by a separation of the V's at the apex, and that in this way we get a true transverse or qualitative division. But from the observations of Farmer, Sargant, Grégoire, Strasburger, and others, it appears that in all such cases the division takes place by a longitudinal splitting of the V, and not by its separation at the apex; and where the V's are produced, not by bending, but by the early longitudinal splitting of the chromosomes, it is evident that their separation at the apex is simply the completion of this longitudinal fission, and not a transverse division at all (Fig. 1, L to P).

**Nucleolus.**

In the majority of plant-nuclei, both in the higher and lower plants, there is found, in addition to the chromatin network, a deeply stained spherical or slightly irregular body (sometimes more than one) called the nucleolus (Fig. 1, A to D). It is often vacuolar, sometimes granular, and in other cases it is a homogeneous body with no visible structure or differentiation. The special function of this organ has been a source of controversy during the past few years, and much uncertainty still exists as to its true nature. There does not appear to be any staining reaction which absolutely separates it from other structures in the cell. In resting nuclei it often stains more deeply than any other of the nuclear constituents. In nuclei in a dividing stage it tends to disappear or break up into granules, and always stains less intensely than in the resting stage. So far as we know at present, there are two distinct types of nucleoli in plants, one of which stains exactly like chromatin in the chromosome stage, the other more like the cytoplasm. Many observers are inclined to the view that true nucleoli do not contain chromatin, but our knowledge of their behaviour towards the various reagents which are stated to differentiate chromatin is not sufficiently definite to allow that view to pass uncriticized. Nor is our knowledge of the morphological behaviour of the nucleolus sufficient to enable us to draw a definite distinction between "true nucleoli" and nucleolus-like bodies. It may be that all these structures should be regarded as true nucleoli of a different chemical nature (Montgomery). The nucleolus is most commonly considered to be a store of reserve material for the use of the nucleus during division, serving also in part to nourish the chromosomes. This view, which was formerly held by Strasburger, is supported by the behaviour of the nucleolus during division. In the resting condition it stains more deeply than the chromatin network, but as the chromosomes are formed it loses its capacity for stains to a large extent, and the staining capacity of the chromosomes at the same time increases; in some cases the nucleolus breaks up, and particles of nucleolar substance are often found attached to the chromosomes, other particles being at the same time found in the cytoplasm. According to Strasburger's more recent explanation, the nucleolus is concerned mainly in the formation of the nuclear spindle. As it dissolves, it is taken up by the kinoplasm, which is thereby stimulated to form the spindle-figure, and the maximum development of the spindle fibres coincides with the complete or partial disappearance of the nucleolus. Another explanation given, which is probably the best, is that the nucleolus is a store of reserve material both for the chromosomes and for the production of the spindle.

**Centrosome.**

The centrosome is a minute homogeneous granule found in the cytoplasm of some cells in the neighbourhood of the nucleus. It is generally surrounded by a clear space, which is in turn surrounded by a granular or radiating cytoplasmic substance, the whole being known as the *centrosphere* or *attraction-sphere*. According to the researches of Van Beneden, Boveri, and others, it is an important special organ of the animal cell, and has been regarded as a regular constituent of it, like the nucleus. It is not so common in plant cells, and its presence has only been certainly demonstrated in the Thallophytes and Bryophytes. In the higher plants the structures which have been often described as centrosomes are too indefinite in their constitution to allow of this interpretation being placed upon them. Even in the lower plants, while the centrospheres may be very apparent, the granules found in them are not sufficiently uniform either in number or general character to allow of their being regarded as centrosomes (Farmer), and many of the centrosomes described are probably nothing more than granules of the fragmented nucleolus, or possibly extra-nuclear nucleoli. They do not appear to be permanent organs of the cell. They are prominent during cell-division, but may disappear in the resting stage. They are more easily seen, when the nucleus is about to undergo mitosis, at the ends

of the spindle, where they form the centres towards which the radiating fibres in the cytoplasm converge. The centrosome or centrosphere is usually regarded as the dynamic centre of the cell and a special organ of division; but its absence in many groups of plants does not lend support to this view so far as plant-cells are concerned.

***Cell membrane.***

The membrane which surrounds the protoplasts in the majority of plants is typically composed of cellulose, together with a number of other substances which are known as pectic compounds. Some of these have a neutral reaction, others react as feeble acids. They can be distinguished by their insolubility in cuprammonia, which dissolves cellulose, and by their behaviour towards stains, some of which stain pectic substances but not cellulose. Cellulose has an affinity for acid stains, pectic substances for basic stains. The cell-membrane may become modified by the process of lignification, suberization, cuticularization, or gelatinization. In the Fungi it is usually composed of a modified form of cellulose known as Fungus cellulose, which, according to Mangin, consists of callose in combination either with cellulose or pectic compounds. It is formed by the protoplasm, either by the direct conversion of the outer cytoplasmic layer into the cell-wall, or by the excretion of the substances which form the cell-wall. In the formation of the new transverse walls which are produced in cell-division, the cell-plate or protoplasmic membrane produced in the equatorial plane of the spindle-fibres appears to be transformed directly into the primary cell-wall. According to Gardiner's recent researches, the nodes of the spindle-fibres persist as the connecting threads of the protoplasts, and are not, as was formerly supposed, merged in the substance of the cell-wall. It is probable, therefore, that the cell-plate is not, as is usually stated, formed by the fusion of the thickened connecting fibres, but that it is formed out of plasmatic substances conducted to and deposited in the cell-plate region by them. According to Strasburger, the cell-plate splits into two, and the new cell-wall is formed as a secretion product between them. Thick cell-walls exhibit a distinct stratification, and the separate layers are composed of thin lamellæ. The primary cell-wall persists as the middle lamella, which appears to be of different chemical composition from the rest of the wall, and to be composed of pectic acid, or a salt of it. By the solution of this middle lamella the cells can be separated from each other. This may take place even in young cells with thin cell-walls. The substance contained in the intercellular spaces, which are formed in some cases between the cells, is probably related to the pectic substances. In many cells there is a distinct striation visible in the cell-wall in addition to the lamination and stratification. These striæ run obliquely and across each other, but the two systems do not occur in the same lamella. We know very little of the minute structure of the cell-wall beyond its lamination and striation. Nägeli considered it to be composed of minute particles of cellulose—*Micellæ*—each surrounded by water. Wiesner suggests that it consists of minute particles or dermatosomes connected together by a delicate protoplasmic network; and there is a certain amount of evidence to show that it is composed of radiating elements somewhat similar to those which are supposed to occur in starch grains. The growth of the cell-wall takes place by the addition of new layers to those already formed. These layers are secreted by the protoplasm by the direct apposition of substances on those already in existence; and they may go on increasing in thickness, both by apposition and by the intussusception of particles probably carried in through the protoplasmic fibres, which penetrate the cell-wall as long as the cell lives. The growth of the cell-wall is very rarely uniform. It is thickened more in some places than in others, and thus are formed the spiral, annular, and other markings, as well as the pits which occur on various cells and vessels. Besides the internal or centripetal growth, some cell-walls are thickened on the outside, such as pollen grains, oospores of Fungi, cells of Peridineæ, &c. This centrifugal growth must apparently take place by the activity of protoplasm external to the cell. The outer protective walls of the oospores of some Fungi are formed out of protoplasm containing numerous nuclei, which is at an early stage separated from the protoplasm of the oosphore. In the Peridineæ, Diatoms, and Desmids, according to recent researches, the thickenings on the outer walls of the cells are due to the passage of protoplasm from the interior of the cell to the outside, through pores which are found perforating the wall on all sides.

Cell-walls may become modified by the impregnation of various substances. Woody or lignified cell-walls appear to contain substances called *coniferin* and *vanillin*, in addition to various other compounds which are imperfectly known. Lignified tissues are coloured yellow by aniline sulphate or aniline chloride, violet with phloroglucin and hydrochloric acid, and characteristic reactions are also given by mixtures containing phenol, indol, skatol, thallin sulphate, &c. (see Zimmerman's *Microtechnique*). Staining reagents can also be used to differentiate lignified cell-walls. Cuticularized or suberized cell-walls occur especially in those cells which perform a protective function. They are impervious to water and gases. Both cuticularized and suberized membranes are insoluble in cuprammonia, and are coloured yellow or brown in a solution of chlor-iodide of zinc. It is probable that the corky or suberized cells do not contain any cellulose (Gilson, Wisselingh); whilst cuticularized cells are only modified in their outer layers, cellulose inner layers being still recognizable. The suberized and cuticularized cell-walls appear to contain a fatty body called suberin, and such cell-walls can be stained red by a solution of alcannin, the lignified and cellulose membranes remaining unstained.

***Protoplasmic continuity.***

Except in the unicellular plants the cell is not an independent unit. Apart from their dependence in various ways upon neighbouring cells, the protoplasts of all plants are probably connected together by fine strands of protoplasm which pass through the cell-wall (Tangl, Russow, Gardiner, Kienitz-Gerloff, and others) (Fig. 2). In *Pinus* the presence of connecting threads has recently been demonstrated throughout all the tissues of the plant. These protoplasmic strands are, except in the case of sieve tubes, so delicate that special methods have to be employed to make them visible. The basis of these methods consists in causing a swelling of the cell-wall by means of sulphuric acid or zinc chloride, and subsequent staining with Hoffmann's blue or other aniline dyes. Fresh tissue may be used, or tissue killed and hardened in dilute solution of iodine, or in osmic acid—uranium-nitrate mixture. Alcohol is not suitable. The results so far obtained show that the connecting threads may be either "pit-threads" which traverse the closing membrane of the pits in the cell-walls (Fig. 2, B), or "wall-threads" which are present in the wall of the cell (Fig. 2, A). Both pit-

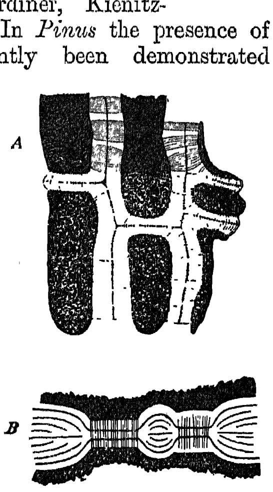

FIG. 2.—Continuity of protoplasm of cells of *Tamus communis* (A) and endosperm of *Lilium Martagon* (B). (*After Gardiner.*)

threads and wall-threads may occur in the same cell, but more often the threads are limited to the pits. The pit-threads are larger and stain more readily than the wall-threads. The threads vary in size in different plants. They are very thick in *Viscum album*, and are well seen in *Phaseolus multiflorus* and *Lilium Martagon*. In epidermal cells (*Tamus communis*, *Lilium Martagon*) the external walls are penetrated by threads which extend to the cuticle. In dead cells the threads appear to be converted into mucilage. These connecting threads probably consist of ectoplasm. They are present from the beginning of the development of the cell-wall, and arise from the spindle fibres, all of which may be continued as connecting threads (Endosperm of *Tamus communis*), or part of them may be overlaid by cellulose lamellæ (Endosperm of *Lilium Martagon*), or they may be all overlaid as in pollen mother-cells and pollen grains of *Helleborus fœtidus*. The presence of these threads between all the cells of the plant shows that the plant body must be regarded as a connected whole; the threads themselves probably play an important part in the growth of the cell-wall, the conduction of food and water, the process of secretion, and the transmission of impulses. In certain cells of the root-apices of plants, however, there exist, according to Němec, longitudinal protoplasmic fibrils which are especially concerned in the conduction of stimuli.

The component parts of the tissues of which plants are composed may consist of but slightly modified cells with copious protoplasmic contents, or of cells which have been modified in various ways to perform their several functions. In some the protoplasmic contents may persist, in others they disappear. The formation of the conducting tubes or secretory sacs which occur in all parts of the higher plants is due either to the elongation of single cells, or to the fusion of cells together in rows by the absorption of the cell-walls separating them. Such cell-fusions may be partial or complete. Cases of complete fusion occur in the formation of laticiferous vessels, and in the spiral, annular, and reticulate vessels of the xylem. Incomplete fusion occurs in sieve tubes. Tubes formed by the elongation of single cells are found in bast fibres, tracheides, and especially in laticiferous cells.

**Laticiferous tissue.**

The laticiferous tissue consists of a network of branching or anastomosing tubes which contain a coagulable fluid known as latex. These tubes penetrate to all parts of the plant and occur in all parts of the root, stem, and leaves. A protoplasmic lining is found on their walls which contains nuclei. The walls are pitted, and protoplasmic connexions between the laticiferous tubes and neighbouring parenchyma-cells have been seen. The fluid sap contains various substances, either in solution or suspended in the form of minute globules, such as sugar, tannin, malic acid in combination with lime, starch-grains, and small globules composed of caoutchouc or resin, which give to the fluid its milky appearance. There are two types of laticiferous tissue—non-articulate and articulate. The non-articulate tissue which occurs in Euphorbiaceæ, Apocyneæ, Urticaceæ, Asclepiadeæ, consists of long tubes, equivalent to single multinucleate cells, which ramify in all directions throughout the plant. The development of laticiferous cells takes place quite early in the embryo, from a group or groups of cells which form a single layer in the pericycle around the central cylinder of the embryo at the cotyledonary node. The number of these initial cells appears to be constant for each species. In some cases a second layer is found just external to the central cylinder, in the cortex, from which a separate cortical system is developed. In other cases the single layer of initial cells gives off branches which penetrate the cortex, central cylinder, and pith (Chauveaud). Laticiferous vessels arise by the coalescence of originally distinct cells. The cells not only fuse together in longitudinal and transverse rows, but put out transverse projections, which fuse with others of a similar nature, and thus form an anastomosing network of tubes which extends to all parts of the plant. They are found in the Compositæ (*Cichoriaceæ*), Campanulaceæ, Papaveraceæ, Lobeliaceæ, Papayaceæ, in some Aroideæ and Musaceæ, and in Euphorbiaceæ (*Manihot*, *Hevea*). The nuclei of the original cells persist in the protoplasmic membrane. Kny has shown that in the Cichoriaceæ hairs containing latex are commonly present, connected to the laticiferous network by means of a narrow opening at the base. The rows of cells from which the laticiferous vessels are formed can be distinguished in many cases in the young embryo while still in the dry seed (Scott), but the latex vessels in process of formation are more easily seen when germination has begun. In the process of cell-fusion the cell-wall swells slightly and then begins to dissolve gradually at some one point. The opening, which is at first very small, increases in size, and before the cross-wall has entirely disappeared, the contents of the two cells become continuous (Scott). The absorption of the cell-walls takes place very early in the germinating seedling.

**Sieve tubes.**

The sieve tubes consist of partially fused rows of cells, the transverse or lateral walls being perforated by minute openings, through which the contents of the cells are connected with each other, and which after a certain time become closed by the formation of callus on the sieve plates. The sieve tubes contain a thin lining layer of protoplasm on their walls, but no nuclei, and the cell sap contains albuminous substances which are coagulable by heat. Starch grains are sometimes present. In close contact with the segments of the sieve tubes are companion cells which communicate with the sieve tubes by delicate protoplasmic strands; they can be distinguished from ordinary parenchymatous cells by their small size and dense protoplasm. Companion cells are not found in the Pteridophyta and Gymnosperms. In the latter their place is taken by certain cells of the medullary rays and bast parenchyma. The companion cells are cut off from the same cells as those which unite to form the sieve tube. The mode of formation of the sieve plate is not certainly known; but from the fact that delicate connecting threads of protoplasm are present between the cells from their first development, it is probable that it is a special case of the normal protoplasmic continuity, the sieve pores being produced by a secondary enlargement of the minute openings, through which these delicate strands pass. According to Lecomte, the young wall consists partly of cellulose and partly of a substance which is not cellulose, the latter existing in the form of slight depressions, which mark the position of the future pores. As the sieve plate grows, these non-cellulose regions swell and gradually become converted into the same kind of mucous substance as that contained in the tube; the two cells are thus placed in open communication. If this is correct, it is easy to see that the changes which take place may be initiated by the original delicate protoplasmic strands which pass through the cell-wall. (For further information regarding tissues, see Anatomy of Plants.)

**Fertilization.**

The formation of the zygote or egg-cell takes place usually by the fusion of the contents of two cells, and always includes, as an essential feature, the fusion of two germ nuclei. In many of the lower plants the fusing cells—*gametes*—are precisely similar so far as size and general appearance are concerned; and the whole contents of the two cells fuse together, cytoplasm with cytoplasm, nucleus with nucleus, nucleolus with nucleolus, and plastid with plastid. The gametes

may be motile (some Algæ) or non-motile, as in *Spirogyra*, *Mucor*, *Basidiobolus*, &c. In many of the lower plants and in all higher plants there is a difference in size in the fusing cells, the male cell being the smaller. The reduction in size is due to the absence of cytoplasm, which is in some cases so small in amount that the cell consists mainly of a nucleus. In all cases of complete sexual differentiation the egg-cell is quiescent, but the male cell may be motile or non-motile. In many of the Fungi the non-motile male cell or nucleus is carried by means of a fertilizing tube actually into the interior of the egg-cell, and is extruded through the apex in close proximity to the egg nucleus. In the Florideæ, Lichens, and Laboulbeniaceæ the male cell is a non-motile spermatium, which is carried to the female organ by movements in the water. In *Monoblepharis*, one of the lower Fungi, in some Algæ, in the Vascular Cryptogams, in Cycads (*Zamia* and *Cycas*), and in *Ginkgo*, an isolated genus of Gymnosperms, the male cell is a motile spermatozoid with two or more cilia. In the Algæ such as *Fucus*, *Volvox*, *Oedogonium*, *Bulbochœte*, and in the Fungus *Monoblepharis*, the spermatozoid is a small oval or elongate cell containing nucleus, cytoplasm, and sometimes plastids. In the Characeæ, the Vascular Cryptogams, in *Zamia* and *Cycas*, and in *Ginkgo*, the spermatozoids are more or less highly modified cells with two or more cilia, and resemble in many respects, both in their structure and mode of formation, the spermatozoids of animals. In Characeæ and Muscineæ they are of elongate spiral form, and consist of an elongate dense nucleus and a small quantity of cytoplasm. At the anterior end are attached two cilia or flagella. In the Vascular Cryptogams the structure is much the same, but a more or less spherical mass of cytoplasm remains attached to the posterior spirals, and a large number of cilia are grouped along the cytoplasmic anterior portion of the spiral. In *Zamia* (Fig. 4, A), *Cycas*, and *Ginkgo* they consist of large spherical or oval cells with a coiled band of cilia at one end, and a large nucleus which nearly fills the cell. They are carried by the pollen tube to the apex of the prothallus, where they are extruded, and by means of their cilia swim through a small quantity of liquid, contained in a slight depression to the oosphere. In the other phanerogams the male cell, which is non-motile, is carried to the oosphere by means of a pollen tube. In the spermatozoids of *Chara*, Vascular Cryptogams, and in those of *Cycas*, *Zamia*, and *Gingko*, the cilia arise from a centrosome-like body which is found on one side of the nucleus of the spermatozoid mother-cell. This body has been called a *blepharoplast*, and in the Pteridophytes, Cycads, and *Gingko* it gives rise to the spiral band on which the cilia are formed. Belajeff regards it as a true centrosome; but this is doubtful, for while in some cases it appears to be connected with the division of the cell, in others it is independent of it. The egg-cell or oosphere is a large cell containing a single large nucleus, and in the green plants the rudiments of plastids. In plants with multinucleate cells, such as *Cystopus*, *Peronospora*, and *Vaucheria*, it is usually a uninucleate cell differentiated by separation of the nuclei from a multinucleate cell, but in *Cystopus Bliti* it is multinucleate, and in *Sphæroplea* it may contain more than one nucleus. In some cases the region where the penetration of the male organ takes place is indicated on the oosphere by a hyaline receptive spot (*Œdogonium*, *Vaucheria*, &c.), or by a receptive papilla consisting of hyaline cytoplasm (Peronosporeæ). Fertilization is effected by the union of two nuclei only in all those cases which have been carefully investigated. Even in the multinucleate oosphere of *Cystopus Bliti* the nuclei fuse in pairs; and in the oospheres of *Sphæroplea*, which may contain more than one nucleus, the egg nucleus is formed by the fusion of one only of these with the spermatozoid nucleus (Klebahn). In the higher Fungi nuclear fusions take place in Basidia or Asci which involve the union of two and sometimes more nuclei, which may be regarded as physiologically equivalent to a sexual fusion. The union of the germ nuclei has now been observed in all the main groups of Angiosperms, Gymnosperms, Ferns, Mosses, Algæ, and Fungi, and presents a striking resemblance in all. In nearly all cases the nuclei appear to fuse in the resting stage (Fig. 3, C). In many Gymnosperms the male nucleus penetrates the female nucleus before fusing with it (Blackman, Ikeno). In other cases the two nuclei place themselves side by side, the nuclear membrane between them disappears, and the contents fuse together—nuclear thread with nuclear thread, and nucleolus with nucleolus—so completely that the separate constituents of the nuclei are not visible. It was at one time thought that the centrosomes played an important part in the fertilization of plants, but recent researches seem to indicate that this is not so. Even in those cases where the cilia band, which is the product of the centrosome-like body or blepharoplast, enters the ovum, as in *Zamia* (*c* in Fig. 4, B, C, D), it appears to take no part in the fertilization phenomena, nor in the subsequent division of the nucleus. During the process of fertilization in the Angiosperms it has been shown by the researches of Nawaschin and Guignard that in *Lilium* and *Fritillaria* both generative nuclei enter the embryo sac, one fusing with the oosphere nucleus, the other with the polar nuclei (Fig. 3 A, B). A double fertilization thus takes place. Both nuclei are elongated vermiform structures, and as they enter the embryo

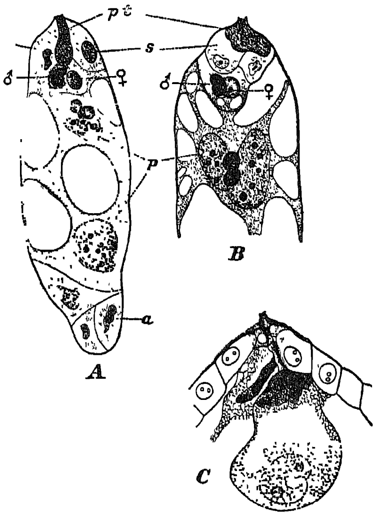

Fig. 3.—Fertilization in the Lily. (*From Wilson, after Guignard and Mottier.*) A, Two vermiform nuclei in the embryo sac; one approaching the egg-nucleus, the other uniting with the upper polar nucleus. B, Union of the vermiform nuclei with the egg-nucleus and the two polar nuclei. C, Fusion of the germ nuclei in the egg-cell; *a*, antipodal cells; *p*, polar nuclei; *pt*, pollen tube.

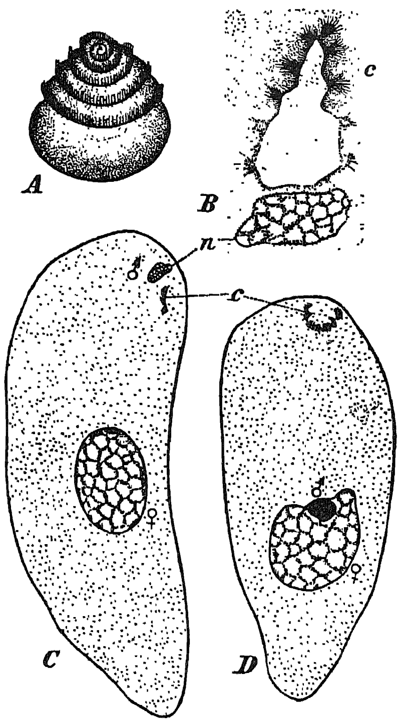

Fig. 4.—Spermatozoid and fertilization in Zamia. (*After Webber.*)

sac present a twisted appearance like a spermatozoid without cilia (Fig. 3, A, B). It has since been shown by other observers that this double fertilization occurs in many other Angiosperms, both Dicotyledons and Monocotyledons, so that it is probably of general occurrence throughout the group (see ANGIOSPERMS).

LITERATURE.—The following is a list of a few of the more important papers in which further information and a more complete list of literature will be found :—

(H. W*.)

**Czaslau** or **Časlau,** chief town of the government district of the same name in Bohemia, Austria. Population (1890), 8396, almost exclusively Czech and Catholic (655 Protestants and 247 Jews); (1900), 9145. There is a garrison of 623 men. A monument was erected in 1880 to the celebrated Hussite leader, Ziska, who was buried in the church. There are a sugar refinery, a brewery, and a distillery.

**Czech Literature** (see BOHEMIA and SLAVS, *Ency. Brit.* 9th edition). The later years of the 19th century saw a continued forward movement in the revived literature of Bohemia; but this progress may be briefly indicated, since its interest is still mainly local, except in so far as the work of Czech writers has helped to vindicate the Bohemian national movement by the reassertion of the Bohemian language as a literary vehicle. Between 1820 and 1848 a new "national school" of writers arose, led by Joseph Jungmann (1773–1847), and including the poets Jan Kollár (1793–1852), J. Kamarýt, Langer, Rubês, and Borovský (1821–56), the dramatists Turniský and Klicpera, and the novelists Jan Marek and Joseph Tyl. Jungmann introduced new models by his translations of British, French, and German literature; the new Czech drama was largely influenced by Shakespeare, and the novel by Sir Walter Scott. This "national school" gradually acquired a Panslavist character, Jungmann himself, the philologist V. Hanka (1791–1861), and the historians P. Šafařík (1795–1861), Franz Palacký (1798–1876), and Tomek (who, born in 1818, was still working at his great *History of Prague* at the end of the century) being the most prominent representatives of this tendency. After 1848 the narrower traditions of the national school gave way before a spirit of cosmopolitanism, introduced by H. Mácha (1810–76), but much encouraged by the influence of Byron; the poets H. Hálek (1835-74) and Jan Neruda (1834–91) being the leading names in this connexion. The national and cosmopolitan schools then became blended in writers of a more eclectic type, like the poets Svatopluk Cěch and "Jaroslav Vrchlický" (pseudonym for Emil Frida), the latter of whom (*b.* 1853) published some twenty volumes of poems, translations, dramas, and essays between 1893 and 1900. His epic poem *Bar-Kochba*, describing the last struggle of the Jews against Rome, is his masterpiece. Between 1890 and 1900 there was a great increase of literary production of all sorts. Julius Zeyer (*b.* 1841), besides writing poetry, has published many romantic prose stories; and Madame "Carolina Svjetla" (pseudonym for Johanna Muzák, *b.* 1830) is a novelist whose tales portray the life of the people. Among recent Czech dramatists must be mentioned Stroupéznický, the brothers Mrštik, Václav Viček, and Václav Frič (pseudonym "Brodsky," *b.* 1829), while Adolph Heyduk (*b.* 1831), has made a name as a poet, and Anton Gindely (1829–92) as a historian.

**Czernowitz** (Rumanian, *Cernâuz*), the capital of the Austrian duchy of Bukovina. Population, with suburbs (1869), 33,884; (1890), 54,171; (1900), 69,619. There is a garrison of 2965 men. There are several rather imposing modern buildings, including the Episcopal Palace in the Byzantine style, the Greek Orthodox cathedral, the Jesuit church, and a Hebrew temple in the Moorish style. The Francis Joseph University, opened in October 1875, has three faculties: theology (Greek Orthodox), law and politics, and philosophy. The language of instruction is German. In 1897 there were 41 professors and lecturers and 390 students. The industry (corn-milling and brewing) is unimportant. The trade, which is in the hands of the Jews and Armenians, is chiefly in corn, timber, cattle, hides, wool, and potash.

**Dacca,** a city of British India, giving its name to a district and division of Bengal. The city is 150 miles north-east by east of Calcutta, on an old channel of the Ganges. Railway station, 10 miles from the terminus of the river steamers at Narayanganj. Its area is about 8 square miles. The population in 1881 was 79,076, in 1891 it was 82,321, and in 1901 it was 90,679. It still shows some signs of its former magnificence. The famous manufacture of fine muslins is almost extinct, but the carving of shells, carried on from ancient times, is an important industry in the city. The Government college had 318 students in 1896, and the collegiate school 556. There is also an unaided Hindu college, with 222 students. There are 20 printing-presses, issuing 3 English and 3 vernacular newspapers. There is a large settlement of mixed Portuguese descent, known as Firinghis. Many of the public buildings, including the college, suffered severely from the earthquake of 12th June 1897.

The DISTRICT comprises an area of 2797 square miles. In 1881 it had a population of 2,113,005, and in 1891 of 2,420,656, giving an average density of 865 persons per square mile. Classified according to religion, Hindus numbered 934,063; Mahommedans, 1,450,250; Christians, 10,476, of whom 223 were Europeans; "others," 813. In 1901 the population was 2,660,631, showing an increase of 11 per cent. The land revenue and rates were Rs.6,08,761; the number of police was 697; the number of boys at school in 1896–97 was 75,836, being 42·4 per cent. of the male population of school-going age; the registered death-rate in 1897 was 27·97 per thousand. The district is now traversed by a line of the Eastern Bengal Railway, and it is further proposed to connect it by branches with the Assam-Bengal Railway; but most of the traffic is still conducted by water. It is a centre of the jute trade. There are 21 steam presses, employing 8000 hands, with an out-turn of 1,427,000 bales; and 10 hand presses, with a capital of Rs.24,00,000, employing 1130 hands, with an out-turn of 130,000 bales.

The DIVISION OF DACCA occupies the delta of the Brahmaputra, where it joins the main stream of the Ganges. It consists of the four districts of Dacca, Mymensingh, Faridpur, and Backergunge. Its area is 15,045 square miles. Its population in 1881 was 8,705,916, and in 1891 it was 9,844,127,—by far the highest rate of increase in Bengal,—with an average density of 654 persons per square mile.

**Daghestan,** a province of Russia, Transcaucasia. It occupies the triangular space between the Andi ridge, the south-east portion of the main Caucasus Range, and the Caspian Sea, and has Terek in N., Tiflis in S.W., Baku in S.E., and Caspian Sea in E. With the exception of a narrow strip of land along the seacoast and a small area in north, it is entirely covered with mountains, and presents one of the most hilly parts of the world. Area, 11,492 square miles. The snowclad Andi ridge, belonging to the system of the south-west to north-east upheavals which cross the Caucasus, branches off the later at Barbalo Peak (10,807 feet), and reaches its highest altitudes in Tebulos-mta (14,781 feet), Great Kachu (14,027 feet), and Donos-mta (13,736 feet). It is encircled on the north by a lower outer ridge, the Black Mountains, pierced by the rivers, and thickly clothed with woods, composed chiefly of beech (Ichkeria). The Bozdakh and another ridge run in the same direction between the four Koisu rivers (Avarian, Andian, Kazy-kumukh, and Kara Koisu), all flowing north-east to make the Sulak, a tributary of the Caspian. The main feature of the country is, however, according to Abich, the succession of folds of Jurassic cretaceous limestones and slates, all nearly parallel to the Caucasus, forming high and barren plateaux. Many peaks rise above 12,000 feet, and the passes are at altitudes of 11,000 feet in the interior of the country and 9000 feet in the east, towards the Caspian. The country is altogether difficult of access, and only one military route leads from Groznyi on the Terek to the military town of Botlikh on the Andi Koisu, while the eleven passes known across the Caucasus are mere bridle-paths. The climate is severe on the plateaux, hot towards the Caspian, and dry everywhere. The average temperatures are: year 51°, January 26°, July 73° at Temir-khan-shura (42° 49′ N., alt. 475 feet). The yearly rainfall varies from 21 to 17 inches.

The population of Daghestan was 590,336 in 1897, out of whom there were only 5000 Russians. It consists chiefly of mountaineers, known under the general name of Lezghians, in the west, and of a mixture of the same with Tatars and Georgians in the Caspian coast region. For a long time the highlands of Daghestan were the stronghold of the Caucasians against the Russians, especially under the leadership of Shamil. The difficulties of communication between the valleys have resulted in the formation of a great number of dialects, or even languages, which have been divided by Baron Uslar into several groups. The Avarian is a sort of inter-tribal tongue, while the Lakh or Kazi-kumukh language, the Kyurin, the Dargo-kaitakh, the Andi, and the Tabasaran are as many separate languages of common origin, subdivided in their turn into a number of dialects.

The mountaineers breed some cattle, and cultivate with great difficulty their small fields on the slopes of the mountains. In the littoral regions excellent crops are obtained with the aid of irrigation. The mountaineers excel also in a variety of petty trades.

A railway line of great importance, connecting the North Caucasian line, Rostov to Petrovsk, with the Transcaucasian line, Batum to Baku, has been built of late. It runs along the sea-coast from Petrovsk, through the Derbent "Gate," to Baku.

The province is divided into nine districts: Temir-khan-shura, Avarian, Andian, Gunib, Dargo, Kazy-kumukh, Kastago-Tabasaran, Kyurinsk, and Samur. The only towns are: Temir-khan-shura, capital of the province (9210 inh.), Derbent on the Caspian (14,821), and Petrovsk, a seaport of some importance (9810). The chief towns of the districts are mere military villages or forts, of which the fort of Gunib, the last stronghold of Shamil, has only 825 inhabitants. (P. A. K.)

**Dagupan,** the most important commercial centre in the province of Pangasinan, Luzon, Philippine Islands, and the northern terminus of the only railway in the islands. It is situated near the mouth of one of the branches of the Agno, but can be approached only by vessels of very small draught, because of a narrow bar at the river's mouth. It has a healthful climate, and is the chief point of exportation for a very rich province, which produces rice, sugar, indigo, Indian corn, and copra in abundance. It has a shipyard in which small sailing vessels and steam launches are constructed. The principal language is Pangasinan. Population, 16,000.

**Dahomey.**—An old West African kingdom, now a French colony, bounded on the S. by the Gulf of Guinea, on the E. by Lagos, on the N. and N.W. by the military territories of the French Sudan, and the W. by Togoland. With a coast-line of only 75 miles, the area after the decree of October 1899 (see below) was estimated at about 59,000 square miles, and the population at about 450,000, but nothing is as yet known with any degree of accuracy on these points. The coast is very low, sandy, and obstructed by a bar. Behind the immediate coast-line is a line of lagoons, where small steamers can ply: that of Porto Novo, on the east, that of Whidah, the longest (26 miles), and that of Grand Popo. The Ofe, the only important river (240 miles), drains the colony from the Bariba country to Porto Novo. The Zu is an affluent. The climate is very hot and moist. Four seasons are well marked: the long dry season, from December 1 to March 15; the season of the great rains, from March 15 to July 15; the short dry season, from July 15 to September 15; and the little rains, from September 15 to December 1. The negroes, of whom the population

entirely consists, belong to the Mina, Ewe, Fou, Mahi, Nago, and Bariba races. Cultivation is primitive and nine-tenths of the lands are waste. Maize, manioc, yams, and potatoes grow along the coast; millet in the interior. The forests contain the baobab, the cocoanut palm and the oil palm. Cattle are rare, and a few years ago the ox was entirely unknown. An experimental farm is carried on at Porto Novo.

France first established factories in 1851 at Whidah, after the signature of a treaty with the king. In 1868 a similar power was granted at Kotonu, and in 1878 France received authority to collect the customs at this locality. In the meantime, in 1863, the kingdom of Porto Novo had accepted the French protectorate, and the Anglo-French agreement of 1864 had fixed its boundaries. This protectorate was soon afterwards abandoned by Napoleon III., but was re-established in 1882; in 1885 a Franco-German convention assigned Grand Popo to France and Little Popo, to the west of the coast of Dahomey, to Germany. In 1890, Gleglé, king of Dahomey, claimed the right to collect the customs at Kotonu, ceded to France in 1878, and to depose the king of Porto Novo, while he also interfered with the French and with the population protected by France. The dispute ended with a treaty which secured to France her rights and to the king of Dahomey an annual pension of £800. In 1892 the attitude of King Behanzin rendered a new war necessary; Abomey, his capital, was taken by General Dodds, his states were annexed, and he himself was sent a prisoner to the Antilles. In 1894 the colony was separated from France's other West African possessions and became a separate administrative unit. Anglo-French conventions of 1889 and 1898 fixed the eastern frontier, and a Franco-German convention of 1897 settled the boundary on the west. The limits northwards were fixed on the disintegration of the French Sudan in 1899, when some of the cantons of Kwala, or Nebba, and the territory of Say, on the Niger, were added to the colony's possessions.

The colony is administered by a governor (himself under the Governor-General of French West Africa), assisted by a council composed of three official and three civil members. It has a paymaster-general and a justice of peace. It is one of the three French West African colonies which have been allowed to manage their own finances, with the result that it is entirely self-supporting. In 1899 the receipts amounted to £110,634, or £34,634 more than was anticipated in the budget. The budget for 1901 anticipated £89,000, of which the native tax was expected to produce £14,000. The principal items of expenditure provided for, apart from £31,000 for the administrative service, were: public works, &c., £21,500; the occupation of Upper Dahomey, £19,000; native troops and police, £9000. The chief towns are Porto Novo (50,000), the seat of government; Grand Popo (2000), a port; Kotonu (1000), a port; Whidah, a port; and in the interior, Abomey (15,000), the capital of Dahomey, 75 miles from the sea, Allada (10,000), and Agony (20,000).

The following table gives the value of the principal articles of import and export for 1898 and 1899, with the totals for those years:—

| Year. | Imports. | | | Exports. | | |
|---|---|---|---|---|---|---|
| | Textiles. | Intoxicants. | Total. | Palm Kernels. | Palm Oil. | Total. |
| 1898 | £83,000 | £155,000 | £400,000 | £170,000 | £109,000 | £301,500 |
| 1899 | 77,000 | 182,000 | 494,000 | ... | ... | 509,000 |

In 1898 Great Britain sent nearly all the textiles, Germany nearly all the intoxicants. The exports of kernels to Lagos was more than half the total, while France and Germany divided the remainder about equally. Lagos and France each received nearly half the oil export. France's total share of the imports in 1898 amounted to only £135,000; of the exports to only £118,300.

France can only slowly increase her sales, the convention of 1898 having guaranteed absolute equality in respect of customs. There are few roads, but a telegraph line connects Kotonu with Abomey, Gurma on the Niger, and Senegal. A railway is projected between Kohonou and the Niger. With Europe there is telegraphic communication (at Kotonu) over an English submarine cable, and steamship communication by lines from Bordeaux and Marseilles and Liverpool and Hamburg. In 1898, of 433 steamers which visited Dahomey, 111 were French, 133 British, and 156 German. French, English, and American coins circulate, and also cowrie shells. The difficulty of firmly establishing French money as the basis of exchange is one of the problems of the colony.

**Daiquiri,** a village 15 miles east of Santiago de Cuba. An expensive iron pier, built by the American shippers of Cuban ores, was used for the landing of the American army in the advance on Santiago in 1898. Population (1899), 1380.

# DAIRY-FARMING.

*Contents*:—

## Modern Changes.

No branch of agriculture underwent greater changes during the closing quarter of the 19th century than dairy-farming; within the period named, indeed, the dairying industry may be said to have been revolutionized. The two great factors in this modification were the introduction about the year 1880 of the centrifugal cream-separator, whereby the old slow system of raising cream in pans was dispensed with, and the invention some ten years later of a quick and easy method of ascertaining the fat content of samples of milk without having to resort to the tedious processes of chemical analysis. About the year 1875 the agriculturists of the United Kingdom, influenced by various economic causes, began to turn their thoughts more intently in the direction of dairy-farming, and to the increased production of milk and cream, butter and cheese. On 24th October 1876 was held the first London Dairy Show, under the auspices of a committee of agriculturists, and it has been followed by a similar show in every subsequent year. The official report of the pioneer show stated that "there was a much larger attendance and a greater amount of enthusiasm in the movement than even the most sanguine of its promoters anticipated." On the day named Professor J. Prince Sheldon read at the show a paper on the dairying industry, and

proposed the formation of a society to be called the British Dairy Farmers' Association. This was unanimously agreed to, and thus was founded an organization which has since been closely identified with the development of the dairying industry of the United Kingdom. In its earlier publications the Association was wont to reproduce from *Household Words* the following tribute to the cow:—

"If civilized people were ever to lapse into the worship of animals, the Cow would certainly be their chief goddess. What a fountain of blessings is the Cow! She is the mother of beef, the source of butter, the original cause of cheese, to say nothing of shoe-horns, hair-combs, and upper leather. A gentle, amiable, ever-yielding creature, who has no joy in her family affairs which she does not share with man. We rob her of her children that we may rob her of her milk, and we only care for her when the robbing may be perpetrated."

The Association has, directly or indirectly, brought about many valuable reforms and improvements in dairying. Its London shows have provided, year after year, a variety of object-lessons in cheese, in butter, and in dairy equipment. In order to demonstrate to producers what is the ideal to aim at, there is nothing more effective than a competitive exhibition of products, and the approach to uniform excellence of character in cheese and butter of whatever kinds is most obvious to those who remember what these products were like at the first two or three dairy shows. Simultaneously there has been a no less marked advance in the mechanical aids to dairying, including, in particular, the centrifugal cream-separator, the crude germ of which was first brought before the public at the International Dairy Show held at Hamburg in the spring of 1877. The Association in good time set the example, now beneficially followed in many parts of Great Britain, of providing means for technical instruction in the making of cheese and butter, by the establishment of a dairy school in the Vale of Aylesbury, subsequently removing it to new and excellent premises at Reading, where it is known as the British Dairy Institute. The initiation of butter-making contests at the annual dairy shows stimulated the competitive instinct of dairy workers, and afforded the public useful object-lessons; in more recent years milking competitions have been added. Milking trials and butter tests of cows conducted at the dairy shows have afforded results of much practical value. Many of the larger agricultural societies have found it expedient to include in their annual shows a working dairy, wherein butter-making contests are held and public demonstrations are given.

What are regarded as the dairy breeds of cattle is illustrated by the prize schedule of the annual London Dairy Show, in which sections are provided for cows and heifers of the Shorthorn, Jersey, Guernsey, Red Polled, Ayrshire, Kerry, and Dexter breeds, the characteristics of which are set forth in the article AGRICULTURE. A miscellaneous class is also provided, the entries in which are mostly cross-breds. There are likewise classes for Shorthorn bulls, Jersey bulls, and bulls of any other pure breed, but it is stipulated that all bulls must be of proved descent from dams that have won prizes in the milking trials or butter tests of the British Dairy Farmers' Association or other high-class agricultural society. The importance of securing dairy characters in the sire is thus recognized, and it is notified that, as the object of the bull classes is to encourage the breeding of bulls for dairy purposes, the prizes are to be given solely to animals exhibited in good stock-getting condition.

## MILK AND BUTTER TESTS.

The award of prizes in connexion with milking trials cannot be determined simply by the quantity of milk yielded in a given period, say twenty-four hours. Other matters must obviously be taken into consideration, such as the quality of the milk and the time that has elapsed since the birth of the last calf. With regard to the former point, for example, it is quite possible for one cow to give more milk than another, but for the milk of the second cow to include the larger quantity of butter-fat. The awards are therefore determined by the total number of points obtained according to the following scheme:—

One point for every ten days since calving (deducting the first forty days), with a maximum of fourteen points.
One point for every pound of milk, taking the average of two days' yield.
Twenty points for every pound of butter-fat produced.
Four points for every pound of "solids other than fat."
*Deductions.*—Ten points each time the fat is below 3 per cent.
Ten points each time the solids other than fat fall below 8·5 per cent.

This method of award is at present the best that can be devised, but it is possible that, as experience accumulates, some rearrangement of the points may be found to be desirable. Omitting many of the details, Table I. shows some of the results in the case of the Shorthorn and Jersey cows to which prizes were awarded in 1900. The days "in milk" denote in each case the number of days that have elapsed since calving; and if the one day's yield of milk is desired in gallons, it can be obtained approximately[1] by dividing the weight in pounds by 10: thus, the Shorthorn cow Heroine III. gave 52·4 lb, or 5·24 gallons, of milk per day. The table is incidentally of interest as showing how superior as milch kine are the unregistered or non-pedigree Shorthorns—which are typical of the great majority of dairy cows in the United Kingdom—as compared with the pedigree animals entered, or eligible for entry, in Coates's Herd-Book. The evening's milk, it should be added, is nearly always richer in fat than the morning's, but the percentages in the table relate to the entire day's milk.

TABLE I. *Prize Shorthorn and Jersey Cows in the Milking Trials, London Dairy Show,* 1900.

| Cow. | Age. | In Milk. | Milk per Day. | Fat. | Other Solids. | Total Points. |
|---|---|---|---|---|---|---|
| | Years. | Days. | lb | Per cent. | Per cent. | No. |
| SHORTHORNS eligible for Herd-Book— | | | | | | |
| Heroine III. | 6 | 61 | 52·4 | 3·7 | 8·3 | 91·5 |
| Musical | 7 | 16 | 45·2 | 3·2 | 9·3 | 90·8 |
| Lady Rosedale | 8 | 48 | 47·8 | 3·5 | 9·0 | 88·7 |
| SHORTHORNS not eligible for Herd-Book— | | | | | | |
| Granny | 9 | 33 | 70·2 | 3·5 | 8·9 | 144·1 |
| Cherry | 9 | 103 | 55·5 | 4·0 | 8·9 | 127·1 |
| Chance | 6 | 23 | 60·0 | 3·6 | 8·9 | 124·6 |
| JERSEYS— | | | | | | |
| Sultane 14th | 12 | .256 | 41·7 | 4·9 | 9·4 | 112 |
| Queen Bess | 7½ | 136 | 39·4 | 4·8 | 9·0 | 101 |
| Gloaming IV. | 7 | 156 | 30·5 | 6·7 | 9·5 | 94·9 |

The milking trials are based upon a chemical test, as it is necessary to determine the percentage of fat and of solids other than fat in each sample of milk. The butter test, on the other hand, is a churn test, as the cream has to be separated from the milk and churned. The following is the scale of points used at the London Dairy Show in making awards in butter tests:—

One point for every ounce of butter; one point for every completed ten days since calving, deducting the first forty days. Maximum allowance for period of lactation, 12 points.

[1] A gallon of milk weighs 10·3 lb, so that very little error is involved in converting pounds to gallons by dividing the number of pounds by 10.

Fractions of ounces of butter, and incomplete periods of less than ten days, to be worked out in decimals and added to the total points.

In the case of cows obtaining the same number of points, the prize to be awarded to the cow that has been the longest time in milk.

No prize or certificate to be given in the case of:—

(a) Cows under five years old failing to obtain 28 points.

(b) Cows five years old and over failing to obtain 32 points.

The manner in which butter tests are decided will be rendered clear by a study of Table II. It is seen that whilst the much larger Shorthorn cows—having a bigger frame to maintain and consuming more food—gave both more milk and more butter in the day of twenty-four hours, the Jersey milk was much the richer in fat. In the case of the first-prize Jersey the "butter ratio," as it is termed, was excellent, as only 13·83 ℔ of milk were required to yield 1 ℔ of butter; in the case of the second-prize Shorthorn, practically twice this quantity (or 27·11 ℔) was needed. Moreover, if the days in milk are taken into account, the difference in favour of the Jersey is seen to be 123 days.

TABLE II. *Prize Shorthorn and Jersey Cows in the Butter Tests, London Dairy Show*, 1900.

| Cows. | Age. | In Milk. | Milk per Day. | Butter. | Milk to 1 ℔ Butter. | Points for Butter. | Points for Lactation. | Total Points. |
|---|---|---|---|---|---|---|---|---|
| | Years. | Days. | ℔ oz. | ℔ oz. | ℔ | No. | No | No. |
| SHORTHORNS— | | | | | | | | |
| 1st | 9 | 104 | 55 2 | 2 5¼ | 23·67 | 37·25 | 6·40 | 43 65 |
| 2nd | 9 | 34 | 72 7 | 2 10½ | 27·11 | 42·75 | .. | 42·75 |
| 3rd | 7 | 33 | 58 5 | 2 7½ | 23·47 | 39·75 | .. | 39·75 |
| JERSEYS— | | | | | | | | |
| 1st | 7 | 157 | 29 10 | 2 2¼ | 13·83 | 34·25 | 11·70 | 45·95 |
| 2nd | 4 | 103 | 33 10 | 2 3 | 15·37 | 35·00 | 6·30 | 41·30 |
| 3rd | 12 | 257 | 40 13 | 1 12 | 23·32 | 28·00 | 12 00 | 40·00 |

The butter-yielding capacity of the choicest class of butter cows, the Jerseys, is amply illustrated in the results of the butter tests conducted by the English Jersey Cattle Society over the period of fourteen years 1886 to 1899 inclusive. These tests have been carried out year after year at half a dozen different shows, and the results are classified in Table III. according to the age of the animals. The average time in milk is measured by the number of days since calving, and the milk and butter yields are those for the day of twenty-four hours. The last column shows the "butter ratio." This number is lower in the case of the Jerseys than in that of the general run of dairy cows. The average results from the total of 1023 cows of the various ages are:—One day's milk, 32 ℔ 2¼ oz., equal to about 3 gallons, or 12 quarts; one day's butter, 1 ℔ 10¾ oz.; butter ratio, 19·13, or about 16 pints of milk to 1 ℔ of butter. Individual yields are sometimes extraordinarily high. Thus at the Tring show in 1899 the three leading Jersey cows gave the following results:—

TABLE III. *Summary of the English Jersey Cattle Society's Butter Tests, Fourteen Years*, 1886 *to* 1899.

| Cows' Ages. | Cows Tested. | Average Time in Milk. | Average Milk Yield. | Average Butter Yield. | Quantity Milk to 1 ℔. Butter. |
|---|---|---|---|---|---|
| Years. | No. | Days. | ℔ oz. | ℔ oz. | ℔ |
| 1 to 2 | 2 | 34 | 15 2 | 0 13 | 18·43 |
| 2 ,, 3 | 57 | 73 | 24 15¼ | 1 5¼ | 18·74 |
| 3 ,, 4 | 108 | 77 | 29 14¾ | 1 10 | 18·42 |
| 4 ,, 5 | 165 | 72 | 32 5½ | 1 11¼ | 19·01 |
| 5 ,, 6 | 188 | 80 | 32 15¼ | 1 12 | 18·76 |
| 6 ,, 7 | 189 | 89 | 34 7¾ | 1 13 | 18·92 |
| 7 ,, 8 | 139 | 84 | 33 11¼ | 1 13¼ | 18·40 |
| 8 ,, 9 | 71 | 82 | 33 6½ | 1 12 | 19·03 |
| 9 ,, 10 | 42 | 92 | 32 6½ | 1 11¼ | 18·95 |
| 10 ,, 11 | 31 | 88 | 35 4 | 1 14¼ | 18·60 |
| 11 ,, 12 | 15 | 89 | 37 1 | 1 13¾ | 19·96 |
| 12 ,, 13 | 13 | 95 | 34 1¼ | 1 10½ | 20·56 |
| 13 ,, 14 | 3 | 54 | 42 1¼ | 2 1¾ | 19·85 |

| Cow. | Age. | Live-Weight. | In Milk. | Butter. | Butter Ratio. |
|---|---|---|---|---|---|
| | Years. | ℔ | Days. | ℔ oz. | ℔ |
| Sundew 4th | 8 | 929 | 77 | 3 6¾ | 15·10 |
| Madeira 5th | 7 | 1060 | 107 | 2 15¼ | 16·14 |
| Em | 7 | 864 | 44 | 3 4¾ | 13·32 |

The eight prize-winning Jerseys on this occasion, with an average weight of 916 ℔ and an average of 117 days in milk, yielded an average of 2 ℔ 9 oz. of butter per cow in the twenty-four hours, the butter ratio working out at 16·69. At the Tring show of 1900 a Shorthorn cow Cherry gave as much as 4 ℔ 4½ oz. of butter in twenty-four hours; she had been in milk 41 days, and her butter ratio worked out at 15·79, which is unusually good for a big cow.

In the six years 1895 to 1900 inclusive 285 cows of the Shorthorn, Jersey, Guernsey, and Red Polled breeds were subjected to butter tests at the London Dairy Show, and the general results are summarized in Table IV.

TABLE IV. *Average Butter Yields and Butter Ratios at the London Dairy Show, Six Years*, 1895 *to* 1900.

| Breed. | No. of Cows. | In Milk. | Butter. | Milk to 1 ℔ Butter. |
|---|---|---|---|---|
| | | Days. | ℔ oz. | ℔ |
| Shorthorn | 106 | 50 | 1 11 | 28·81 |
| Jersey | 126 | 99 | 1 10¼ | 19·15 |
| Guernsey | 23 | 72 | 1 9½ | 21·86 |
| Red Polled | 30 | 60 | 1 4¼ | 30·29 |

Although cows in the showyard may perhaps be somewhat upset by their unusual surroundings, and thus not yield so well as at home, yet the average results of these butter-test trials over a number of years are borne out by the private trials that have taken place in various herds. The trials have, moreover, brought into prominence the peculiarities of different breeds, such as: (*a*) that the Shorthorns, Red Polls, and Kerries, being cattle whose milk contains small fat globules, are better for milk than the Jerseys and Guernseys, whose milk is richer, containing larger-sized fat globules, and is therefore more profitable for converting into butter; (*b*) that the weights of the animals, and consequently the proportionate food, must be taken into account in estimating the cost of the dairy produce; (*c*) that the influence of the stage reached in the period of lactation is much more marked in some breeds than in others.

An instructive example of the milk-yielding capacity of Jersey cows is afforded in the carefully kept records of Lord Rothschild's herd at Tring Park, Herts. The following are the figures, the gallons being calculated at the rate of 10 ℔ of milk to the gallon:—

In 1897, 30 cows averaged 6396 ℔, or 640 gallons per cow.
In 1898, 29 ,, ,, 6209 ,, 621 ,, ,,
In 1899, 37 ,, ,, 6430 ,, 643 ,, ,,
In 1900, 39 ,, ,, 6136 ,, 614 ,, ,,

The average over the four years works out at about 630 gallons per cow per annum.

Cows of larger type will give more milk than the Jerseys, but it is less rich in fat. The milk record for the year 1900 of the herd of Red Polled cattle belonging to Mr Garrett Taylor, Whitlingham, Norfolk, affords a good example. The cows in the herd, which had before

1900 produced one or more calves, and in 1900 added another to the list, being in full profit the greater part of the year, numbered 82. Their total yield was 521,950 lb of milk, or an average of 6365 lb—equivalent to about 636 gallons—per cow. In 1899 the average yield of 96 cows was 6283 lb, or 628 gallons; in 1898 the average yield of 75 cows was 6473 lb, or 647 gallons. Of cows which dropped a first calf in the autumn of 1899, one of them—Lemon—milked continuously for 462 days, yielding a total of 7166 lb of milk, being still in milk when the herd year closed on 27th December. Similar cases were those of Nora, which gave 9066 lb of milk in 455 days; Doris, 8138 lb in 462 days; Brisk, 9248 lb in 469 days; Della, 8806 lb in 434 days, drying 28 days before the year ended; and Lottie, 6327 lb in 394 days, also drying 28 days before the year ended; these were all cows with their first calf. Eight cows in the herd gave milk on every day of the 52 weeks, and 30 others had their milk recorded on 300 days or more. Three heifers which produced a first calf before 11th April 1900, averaged in the year 4569 lb of milk, or about 456 gallons. In 1900 three cows, Eyke Jessie, Kathleen, and Doss, each gave over 10,000 lb, or 1000 gallons of milk; four cows gave from 9000 lb to 10,000 lb, two from 8000 lb to 9000 lb, 17 from 7000 lb to 8000 lb, 19 from 6000 lb to 7000 lb, 30 from 5000 lb to 6000 lb, and 16 from 4000 lb to 5000 lb. The practice, long followed at Whitlingham, of developing the milk-yielding habit by milking a young cow so long as she gives even a small quantity of milk daily, is well supported by the figures denoting the results.

Though milking trials and butter tests are not usually available to the ordinary dairy farmer in the management of his herd, it is, on the other hand, a simple matter for him to keep what is known as a milk register. By a milk register is meant a record of the quantity of milk yielded by a cow. In other words, it is a quantitative estimation of the milk the cow gives. It affords no information as to the quality of the milk, or as to its butter-yielding or cheese-yielding capacity. Nevertheless, by its aid the milk-producing capacity of a cow can be ascertained exactly, and her character in this respect can be expressed by means of figures about which there need be no equivocation. A greater or less degree of exactness can be secured, according to the greater or less frequency with which the register is taken. Even a weekly register would give a fair idea as to the milk yields of a cow, and would be extremely valuable as compared with no register at all.

The practice of taking the milk register, as followed in a well-known dairy, may be briefly described. The cows are always milked in the stalls, and during summer they are brought in twice a day for this purpose. After each cow is milked, the pail containing the whole of her milk is hung on a spring balance suspended in a convenient position, and from the gross weight indicated there is deducted the already known weight of the pail.[1] The difference, which represents the weight of milk, is recorded in a book suitably ruled. This book when open presents a view of one week's records. In the left-hand column are the names of the cows; on the right of this are fourteen columns, two of which receive the morning and evening record of each cow. In a final column on the right appears the week's total yield for each cow; and space is also allowed for any remarks. Fractions of a pound are not entered, but 18 lb 12 oz. would be recorded as 19 lb, whereas 21 lb 5 oz. would appear as 21 lb, so that a fraction of over half a pound is considered as a whole pound, and a fraction of under half a pound is ignored. By dividing the pounds by 10 the yield in gallons is readily ascertained.

Every dairy farmer has some idea, as to each of his cows, whether she is a good, a bad, or an indifferent milker, but such knowledge is at best only vague. By the simple means indicated the character of each cow as a milk-producer is slowly but surely recorded in a manner which is at once exact and definite. Such a record is particularly valuable to the farmer, in that it shows to him the relative milk-yielding capacities of his cows, and thus enables him gradually to weed out the naturally poor milkers and replace them by better ones. It also guides him in regulating the supply of food according to the yield of milk. The register will, in fact, indicate unerringly which are the best milk-yielding cows in the dairy, and which therefore are, with the milking capacity in view, the best to breed from.

The simplicity and inexpensiveness of the milk register must not be overlooked. These are features which should commend it especially to the notice of small dairy farmers, for with a moderate number of cows it is particularly easy to introduce the register. But even with a large dairy it will be found that, as soon as the system has got fairly established, the additional time and trouble involved will sink into insignificance when compared with the benefits which accrue.

The importance of ascertaining not only the quantity but also the quality of milk is aptly illustrated in the case of two cows at the Tring show, 1900. The one cow gave in 24 hours $4\frac{1}{2}$ gallons of milk, which at 7d. per gallon would work out at about 2s. 7d.; she made 2 lb 12 oz. of butter, which at 1s. 4d. per lb would bring in 3s. 8d.; consequently by selling the milk the owner lost about 1s. 1d. per day. The second cow gave $5\frac{1}{3}$ gallons of milk, which would work out at 3s. 1d.; she made 1 lb 12 oz. of butter, which would only be worth 2s. 4d., so that by converting the milk into butter the owner lost 9d. per day.

The colour of milk is to some extent an indication of its quality—the deeper the colour the better the quality. The colour depends upon the size of the fat globules, a deep yellowish colour indicating large globules of fat. When the globules are of large size the milk will churn more readily, and the butter is better both in quality and in colour.

The following fifty dairy rules relating to the milking and general management of cows, and to the care of milk and dairy utensils, were drawn up on behalf of, and published by, the United States Department of Agriculture at Washington. They are given here with a few merely verbal alterations:—

THE OWNER AND HIS HELPERS.

1. Read current dairy literature and keep posted on new ideas.
2. Observe and enforce the utmost cleanliness about the cattle, their attendants, the cow house, the dairy, and all utensils.
3. A person suffering from any disease, or who has been exposed to a contagious disease, must remain away from the cows and the milk.

THE COW HOUSE.

4. Keep dairy cattle in a shed or building by themselves. It is preferable to have no cellar below and no storage loft above.
5. Cow houses should be well ventilated, lighted, and drained; should have tight floors and walls, and be plainly constructed.
6. Never use musty or dirty litter.
7. Allow no strong-smelling material in the cow house for any length of time. Store the manure under cover outside the cow house, and remove it to a distance as often as practicable.

[1] A portable milk-weighing appliance is made in which the weight of the pail is included, and an indicator shows on a dial the exact weight in pounds and ounces, and likewise the volume in gallons and pints, of the milk in the pail. When the pail is empty the indicator of course points to zero.

8. Whitewash the cow house once or twice a year; use gypsum in the manure gutters daily.
9. Use no dry, dusty feed just previous to milking; if fodder is dusty, sprinkle it before it is fed.
10. Clean and thoroughly air the cow house before milking; in hot weather sprinkle the floor.
11. Keep the cow house and dairy room in good condition, and then insist that the dairy, factory, or place where the milk goes be kept equally well.

THE COWS.

12. Have the herd examined at least twice a year by a skilled veterinarian.
13. Promptly remove from the herd any animal suspected of being in bad health, and reject her milk. Never add an animal to the herd until it is ascertained to be free from disease, especially tuberculosis.
14. Do not move cows faster than a comfortable walk while on the way to the place of milking or feeding.
15. Never allow the cows to be excited by hard driving, abuse, loud talking, or unnecessary disturbance; do not expose them to cold or storms.
16. Do not change the feed suddenly.
17. Feed liberally, and use only fresh, palatable feed-stuffs; in no case should decomposed or mouldy material be used.
18. Provide water in abundance, easy of access, and always pure; fresh, but not too cold.
19. Salt should always be accessible to the cows.
20. Do not allow any strong-flavoured food, like garlic, cabbages, and turnips, to be eaten, except immediately after milking.
21. Clean the entire skin of the cow daily. If hair in the region of the udder is not easily kept clean, it should be clipped.
22. Do not use the milk within twenty days before calving, nor for three to five days afterwards.

MILKING.

23. The milker should be clean in all respects; he should not use tobacco while milking; he should wash and dry his hands just before milking.
24. The milker should wear a clean outer garment, used only when milking and kept in a clean place at other times.
25. Brush the udder and surrounding parts just before milking, and wipe them with a clean damp cloth or sponge.
26. Milk quietly, quickly, cleanly, and thoroughly. Cows do not like unnecessary noise or delay. Commence milking at exactly the same hour every morning and evening, and milk the cows in the same order.
27. Throw away (but not on the floor—better in the gutter) the first two or three streams from each teat; this milk is very watery and of little value, but it may injure the rest.
28. If in any milking a part of the milk is bloody or stringy or unnatural in appearance, the whole should be rejected.
29. Milk with dry hands; never let the hands come in contact with the milk.
30. Do not allow dogs, cats, or loafers to be around at milking time.
31. If any accident occurs by which a pail, full or partly full, of milk becomes dirty, do not try to remedy this by straining, but reject all this milk and rinse the pail.
32. Weigh and record the milk given by each cow, and take a sample morning and night, at least once a week, for testing by the fat test.

CARE OF MILK.

33. Remove the milk of every cow at once from the cow house to a clean dry room, where the air is pure and sweet. Do not allow cans to remain in the cow house while they are being filled with milk.
34. Strain the milk through a metal gauze and a flannel cloth or layer of cotton as soon as it is drawn.
35. Cool the milk as soon as strained—to 45° F. if the milk is for shipment, or to 60° if for home use or delivery to a factory.
36. Never close a can containing warm milk.
37. If the cover is left off the can, a piece of cloth or mosquito netting should be used to keep out insects.
38. If milk is stored, it should be kept in tanks of fresh cold water (renewed as often as the temperature increases to any material extent), in a clean, dry, cold room. Unless it is desired to remove cream, it should be stirred with a tin stirrer often enough to prevent the forming of a thick cream layer.
39. Keep the night milk under shelter so that rain cannot get into the cans. In warm weather keep it in a tank of fresh cold water.
40. Never mix fresh warm milk with that which has been cooled.
41. Do not allow the milk to freeze.
42. In no circumstances should anything be added to milk to prevent its souring. Cleanliness and cold are the only preventives needed.
43. All milk should be in good condition when delivered at a creamery or a cheesery. This may make it necessary to deliver twice a day during the hottest weather.
44. When cans are hauled far they should be full, and carried in a spring waggon.
45. In hot weather cover the cans, when moved in a waggon, with a clean wet blanket or canvas.

THE UTENSILS.

46. Milk utensils for farm use should be made of metal and have all joints smoothly soldered. Never allow them to become rusty or rough inside.
47. Do not haul waste products back to the farm in the cans used for delivering milk. When this is unavoidable, insist that the skim milk or whey tank be kept clean.
48. Cans used for the return of skim milk or whey should be emptied, scalded, and cleaned as soon as they arrive at the farm.
49. Clean all dairy utensils by first thoroughly rinsing them in warm water; next clean inside and out with a brush and hot water in which a cleaning material is dissolved; then rinse and, lastly, sterilize by boiling water or steam. Use pure water only.
50. After cleaning, keep utensils inverted in pure air, and sun if possible, until wanted for use.

### Food and Milk Production.

In their comprehensive paper relating to the feeding of animals, published in 1895, Lawes and Gilbert discussed amongst other questions that of milk production, and directed attention to the great difference in the demands made on the food—on the one hand for the production of meat (that is, of animal increase), and on the other for the production of milk. Not only, however, do cows of different breeds yield different quantities of milk, and milk of characteristically different composition, but individual animals of the same breed have very different milk-yielding capacity; and whatever the capacity of a cow may be, she has a maximum yield at one period of her lactation, which is followed by a gradual decline. Hence, in comparing the amounts of constituents stored up in the fattening increase of an ox with the amounts of the same constituents removed in the milk of a cow, it is necessary to assume a wide range of difference in the yield of milk. Accordingly, Table V. shows the amounts of nitrogenous substance, of fat, of non-nitrogenous substance not fat, of mineral matter, and of total solid matter, carried off in the weekly yield of milk of a cow, on the alternative assumptions of a production of 4, 6, 8, 10, 12, 14, 16, 18, or 20 quarts per head per day. For comparison, there is given at the foot of the table the amounts of nitrogenous substance, of fat, of mineral matter, and of total solid matter, in the weekly increase in live-weight of a fattening ox of an average weight of 1000 ℔—first, on the assumption of a weekly increase of 10 ℔, and, secondly, of 15 ℔. The estimates of the amounts of constituents in the milk are based on the assumption that it will contain 12·5 per cent. of total solids—consisting of 3·65 albuminoids, 3·50 butter-fat, 4·60 sugar, and 0·75 of mineral matter. The estimates of the constituents in the fattening increase of oxen are founded on determinations made at Rothamsted.

With regard to the very wide range of yield of milk per head per day which the figures in the following table assume, it may be remarked that it is by no means impossible that the same animal might yield the largest amount, namely, 20 quarts, or 5 gallons, per day near the beginning, and only 4 quarts, or 1 gallon, or even less, towards the end of her period of lactation. At the same time, an entire herd of, for example, Shorthorns or Ayrshires, of fairly average quality, well fed, and including animals at various periods

of lactation, should not yield an average of less than 8 quarts, or 2 gallons, and would seldom exceed 10 quarts, or $2\frac{1}{2}$ gallons, per head per day the year round.

TABLE V. *Comparison of the Constituents of Food carried off in Milk, and in the Fattening Increase of Oxen.*

| [1 Gallon=10·33 ℔.] | Nitrogenous Substance. | Fat. | Non-Nitrogenous Substance not Fat (Sugar). | Mineral Matter. | Total Solid Matter. |
|---|---|---|---|---|---|
| *In Milk per Week.* | | | | | |
| If:— | ℔ | ℔ | ℔ | ℔ | ℔ |
| 4 quarts per head per day | 2·64 | 2·53 | 3·33 | 0·54 | 9·04 |
| 6 ,, ,, ,, | 3·96 | 3·80 | 4·99 | 0·81 | 13·56 |
| 8 ,, ,, ,, | 5·28 | 5·06 | 6·66 | 1·08 | 18·08 |
| 10 ,, ,, ,, | 6·60 | 6·33 | 8·32 | 1·35 | 22·60 |
| 12 ,, ,, ,, | 7·92 | 7·59 | 9·99 | 1·62 | 27·12 |
| 14 ,, ,, ,, | 9·24 | 8·86 | 11·65 | 1·89 | 31·64 |

| 18 ,, ,, ,, | 11·88 | 11·39 | 14·98 | 2·43 | 40·68 |
| 20 ,, ,, ,, | 13·20 | 12·65 | 16·65 | 2·70 | 45·20 |
| *In Increase in Live-Weight per Week.—Oxen.* | | | | | |
| If 10 ℔ increase . . | 0·75 | 6·35 | ... | 0·15 | 7·25 |
| If 15 ℔ increase . . | 1·13 | 9·53 | ... | 0·22 | 10·88 |

For the sake of illustration, an average yield of milk of 10 quarts, equal $2\frac{1}{2}$ gallons, or between 25 and 26 ℔ per head per day, may be assumed, and the amount of constituents in the weekly yield at this rate may be compared with that in the weekly increase of the fattening ox at the higher rate assumed in the table, namely, 15 ℔ per 1000 ℔ live-weight, or 1·5 per cent. per week. It is seen that whilst of the nitrogenous substance of the food the amount stored up in the fattening increase of an ox would be only 1·13 ℔, the amount carried off as such in the milk would be 6·6 ℔, or nearly six times as much. Of mineral matter, again, whilst the fattening increase would only require about 0·22 ℔, the milk would carry off 1·35 ℔, or again about six times as much. Of fat, however, whilst the fattening increase would contain 9·53 ℔, the milk would contain only 6·33 ℔, or only about two-thirds as much. On the other hand, whilst the fattening increase contains no other non-nitrogenous substance than fat, the milk would carry off 8·32 ℔ in the form of milk-sugar. This amount of milk-sugar, reckoned as fat, would correspond approximately to the difference between the fat in the milk and that in the fattening increase.

It is evident, then, that the drain upon the food is very much greater for the production of milk than for that of meat. This is especially the case in the important item of nitrogenous substance; and if, as is frequently assumed, the butter-fat of the milk is at any rate largely derived from the nitrogenous substance of the food, so far as it is so at least about two parts of such substance would be required to produce one of fat. On such an assumption, therefore, the drain upon the nitrogenous substance of the food would be very much greater than that indicated in the table as existing as nitrogenous substance in the milk. To this point further reference will be made presently.

Attention may next be directed to the amounts of food, and of certain of its constituents, consumed for the production of a given amount of milk. This point is illustrated in Table VI., which shows the constituents consumed per 1000 ℔ live-weight per day in the case of the Rothamsted herd of 30 cows in the spring of 1884. On the left hand are shown the actual amounts of the different foods consumed per 1000 ℔ live-weight per day; and in the respective columns are recorded—first the amounts of total dry substance which the foods contained, and then the amounts of digestible nitrogenous, digestible non-nitrogenous (reckoned as starch), and digestible total organic substance which the different foods would supply; these being calculated according to Lawes and Gilbert's own estimates of the percentage composition of the foods, and to Wolff's estimates of the proportion of the several constituents which would be digestible.

The first column shows that the amount of total dry substance of food actually consumed by the herd, per 1000 ℔ live-weight per day, was scarcely 20 ℔, whilst Wolff's[1] estimated requirement, as stated at the foot of the table, is 24 ℔. But his ration would doubtless consist to a greater extent of hay and straw-chaff, containing a larger proportion of indigestible and effete woody fibre. The figures show, indeed, that the Rothamsted ration supplied, though nearly the same, even a somewhat less amount of total digestible constituents than Wolff's.

TABLE VI. *Constituents consumed per* 1000 ℔ *Live-Weight per Day, for Sustenance and for Milk-Production. The Rothamsted Herd of* 30 *Cows, Spring* 1884.

* Albuminoid ratio, 1–4·4.
† Exclusive of 0·4 fat; albuminoid ratio, 1–5·4.

Of digestible nitrogen substance, the food supplied 2·64 ℔ per day, whilst the amount estimated to be required for sustenance merely is 0·57 ℔; leaving, therefore, 2·07 ℔ available for milk-production. The 23·3 ℔ of milk yielded per 1000 ℔ live-weight per day would, however, contain only 0·85 ℔; and there would thus remain an apparent excess of 1·22 ℔ of digestible nitrogenous substance in the food supplied. But against the amount of 2·64 ℔ actually consumed, Wolff's estimate of the amount required for sustenance and for milk-production is 2·5 ℔, or but little less than the amount actually consumed at Rothamsted. On the assumption that the expenditure of nitrogenous substance in the production of milk is only in the formation of the nitrogenous substances of the milk, there would appear to have been a considerable excess given in the food. But Wolff's estimate assumes no excess of supply, and that the whole is utilized; the fact being that he supposes the butter-fat of

[1] *Landw. Fütterungslehre*, 5te Aufl., 1888, p. 249.

the milk to have been derived largely, if not wholly, from the albuminoids of the food.

It has been shown that although it is possible that some of the fat of a fattening animal may be produced from the albuminoids of the food, certainly the greater part of it, if not the whole, is derived from the carbohydrates. But the physiological conditions of the production of milk are so different from those for the production of fattening increase, that it is not admissible to judge of the sources of the fat of the one from what may be established in regard to the other. It has been assumed, however, by those who maintain that the fat of the fattening animal is formed from albuminoids, that the fat of milk must be formed in the same way. Disallowing the legitimacy of such a deduction, there do, nevertheless, seem to be reasons for supposing that the fat of milk may, at any rate in large proportion, be derived from albuminoids.

Thus, as compared with fattening increase, which may in a sense be said to be little more than an accumulation of reserve material from excess of food, milk is a special product, of a special gland, for a special normal exigency of the animal. Further, whilst common experience shows that the herbivorous animal becomes the more fat the more, within certain limits, its food is rich in carbohydrates, it points to the conclusion that both the yield of milk and its richness in butter are more connected with a liberal supply of the nitrogenous constituents in the food. Obviously, so far as this is the case, it may be only that thereby more active change in the system, and therefore greater activity of the special function, is maintained. The evidence at command is, at any rate, not inconsistent with the supposition that a good deal of the fat of milk may have its source in the breaking up of albuminoids, but direct evidence on the point is still wanting; and supposing such breaking up to take place in the gland, the question arises—What becomes of the by-products? Assuming, however, that such change does take place, the amount of nitrogenous substance supplied to the Rothamsted cows would be less in excess of the direct requirement for milk-production than the figures in the table would indicate—if, indeed, in excess at all.

The figures in the column of Table VI. relating to the estimated amount of digestible non-nitrogenous substance reckoned as starch show that the quantity actually consumed was 11·71 ℔, whilst the amount estimated by Wolff to be required was 12·5 ℔, besides 0·4 ℔ of fat. The figures further show that, deducting 7·4 ℔ for sustenance from the quantity actually consumed, there would remain 4·31 ℔ available for milk-production, whilst only about 3·02 ℔ would be required supposing that both the fat of the milk and the sugar had been derived from the carbohydrates of the food; and according to this calculation, there would still be an excess in the daily food of 1·29 ℔. It is to be borne in mind, however, that estimates of the requirement for mere sustenance are mainly founded on the results of experiments in which the animals are allowed only such a limited amount of food as will maintain them without either loss or gain when at rest. But physiological considerations point to the conclusion that the expenditure, independently of loss or gain, will be the greater the more liberal the ration; and hence it is probable that the real excess, if any, over that required for sustenance and milk-production would be less than that indicated in the table, which is calculated on the assumption of a fixed requirement for sustenance for a given live-weight of the animal. Supposing that there really was any material excess of either the nitrogenous or the non-nitrogenous constituents supplied over the requirement for sustenance and milk-production, the question arises—Whether, or to what extent, it conduced to increase in live-weight of the animals, or whether it was in part, or wholly, voided, and so wasted?

As regards the influence of the period of the year, with its characteristic changes of food, on the quantity and composition of the milk, the first column of the second division of Table VII. shows the average yield of milk per head per day of the Rothamsted herd, averaging about 42 cows, almost exclusively Shorthorns, in each month of the year, over six years, 1884 to 1889 inclusive; and the succeeding columns show the amounts of butter-fat, of solids not fat, and of total solids in the average yield per head per day in each month of the year, calculated, not according to direct analytical determinations made at Rothamsted, but according to the results of more than 14,000 analyses made, under the superintendence of Dr Vieth, in the laboratory of the Aylesbury Dairy Company in 1884;[1] the samples analysed representing the milk from a great many different farms in each month.

* Average over five years only, as the records did not commence until February 1884.

It should be stated that the Rothamsted cows had cake throughout the year; at first 4 ℔ per head per day, but afterwards graduated according to the yield of milk, on the basis of 4 ℔ for a yield of 28 ℔ of milk, the result being that then the amount given averaged more per head per day during the grazing period, but less earlier and later in the year. Bran, hay and straw-chaff, and roots (generally mangel), were also given when the animals were not turned out to grass. The general plan was, therefore, to give cake alone in addition when the cows were turned out to grass, but some other dry food, and roots, when entirely in the shed during the winter and early spring months.

Referring to the column showing the average yield of milk per head per day each month over the six years, it will be seen that during the six months—January, February, September, October, November, and December—the average yield was sometimes below 20 ℔, and on the average only about 21 ℔ of milk per head per day; whilst over the other six months it averaged 27·63 ℔, and over May and June more than 31 ℔, per head

[1] *The Analyst*, April 1885, vol. x. p. 67.

per day. That is to say, the quantity of milk yielded was considerably greater during the grazing period than when the animals had more dry food, and roots instead of grass.

Next, referring to the particulars of composition, according to Dr Vieth's results, which may well be considered as typical for the different periods of the year, it is seen that the specific gravity of the milk was only average, or lower than average, during the grazing period, but rather higher in the earlier and later months of the year. The percentage of total solids was rather lower than the average at the beginning of the year, lowest during the chief grazing months, but considerably higher in the later months of the year, when the animals were kept in the shed and received more dry food. The percentage of butter-fat follows very closely that of the total solids, being the lowest during the best grazing months, but considerably higher than the average during the last four or five months of the year, when more dry food was given. The percentage of solids not fat was considerably the lowest during the later months of the grazing period, but average, or higher than average, during the earlier and later months of the year. It may be observed that, according to the average percentages given in the table, a gallon of milk will contain more of both total solids and of butter-fat in the later months of the year; that is, when there is less grass and more dry food given.

Turning to the last three columns of the table, it is seen that although, as has been shown, the percentage of the several constituents in the milk is lower during the grazing months, the actual amounts contained in the quantity of milk yielded per head are distinctly greater during those months. Thus, the amount of butter fat yielded *per head per day* is above the average of the year from April to September inclusive; the amounts of solids not fat are over average from April to August inclusive; and the amounts of total solids yielded are average, or over average, from April to August inclusive.

From the foregoing results it is evident that the quantity of milk yielded per head is very much the greater during the grazing months of the year, but that the percentage composition of the milk is lower during that period of higher yield, and considerably higher during the months of more exclusively dry-food feeding. Nevertheless, owing to the much greater quantity of milk yielded during the grazing months, the actual quantity of constituents yielded per cow is greater during those months than during the months of higher percentage composition but lower yield of milk per head. It may be added that a careful consideration of the number of newly-calved cows brought into the herd each month shows that the results as above stated were perfectly distinct, independently of any influence of the period of lactation of the different individuals of the herd.

The few results which have been brought forward in relation to *milk-production* are admittedly quite insufficient adequately to illustrate the influence of variation in the quantity and composition of the food on the quantity and composition of the milk yielded. Indeed, owing to the intrinsic difficulties of experimenting on such a subject, involving so many elements of variation, any results obtained have to be interpreted with much care and reservation. Nevertheless, it may be taken as clearly indicated that, within certain limits, high feeding, and especially high nitrogenous feeding, does increase both the yield and the richness of the milk.[1] But it is evident that when high feeding is pushed beyond a comparatively limited range, the tendency is to increase the weight of the animal—that is, to favour the development of the individual, rather than to enhance the activity of the functions connected with the reproductive system. This is, of course, a disadvantage when the object is to maintain the milk-yielding condition of the animal; but when a cow is to be fattened off it will be otherwise.

It has been stated that, early in the period of six years in which the Rothamsted results that have been quoted were obtained, the amount of oil-cake given was graduated according to the yield of milk of each individual cow; as it seemed unreasonable that an animal yielding, say, only four quarts per day, should receive, beside the home foods, as much cake as one yielding several times the quantity. The obvious inference is, that any excess of food beyond that required for sustenance and milk-production would tend to increase the weight of the animal, which, according to the circumstances, may or may not be desirable.

It may be observed that direct experiments at Rothamsted confirm the view, arrived at by common experience, that roots, and especially mangel, have a favourable effect on the flow of milk. Further, the Rothamsted experiments have shown that a higher percentage of butter-fat, of other solids, and of total solids, was obtained with mangel than with silage as the succulent food. The yield of milk was, however, in a much greater degree increased by grazing than by any other change in the food; and at Rothamsted the influence of roots comes next in order to that of grass, though far behind it, in this respect. But with grazing, as has been shown, the percentage composition of the milk is considerably reduced; though, owing to the greatly increased quantity yielded, the amount of soil-constituents removed in the milk when cows are grazing may nevertheless be greater per head per day than under any other conditions. Lastly, it has been clearly illustrated how very much greater is the demand upon the food, especially for nitrogenous and for mineral constituents, in the production of milk than in that of fattening increase.

### Manurial Value of Food consumed in the Production of Milk.

In any attempt to estimate the average value of the manure derived from the consumption of food for the production of milk, the difficulty arising from the very wide variation in the amount of milk yielded by different cows, or by the same cow at different periods of her lactation, is increased by the inadequate character of information concerning the difference in the amount of the food actually consumed by the animal coincidently with the production of such different amounts of milk. But although information is lacking for correlating, with numerical accuracy, the great differences in milk-yield of

[1] The evidence on this point taken by the Committee on Milk and Cream Regulations in 1900 is somewhat conflicting. The report states that an impression commonly prevails that the quality of milk is more or less determined by the nature and composition of the food which the cow receives. One witness said that farmers who produce milk for sale feed differently from what they do if they are producing for butter. Another stated that most of the statistics which go to show that food has no effect on milk fail, because the experiments are not carried far enough to counterbalance that peculiarity of the animal first to utilize the food for itself before utilizing it for the milk. A witness who kept a herd of 100 milking cows expressed the opinion that improvement in the quality of milk can be effected by feeding, though not to any large extent. On the other hand, it was maintained that the fat percentage in the milk of a cow cannot be raised by any manner or method of feeding. It is possible that in the case of cows very poorly fed the addition of rich food would alter the composition of their milk, but if the cows are well-fed to begin with, this would not be so. The proprietor of a herd of 500 milking cows did not think that feeding affected the quality of milk from ordinarily well-kept animals. An experimenter found that the result of resorting to rather poor feeding was that the first effect was produced upon the weight of the cow and not upon the milk; the animal began to get thin, losing its weight, though there was not very much effect upon the quality of the milk.

individual cows with the coincident differences in consumption to produce it, it may be considered as satisfactorily established that more food is consumed by a herd of cows to produce a fair yield of milk, of say 10 or 12 quarts per head per day, than by an equal live-weight of oxen fed to produce fattening increase. In the cases supposed it may, for practical purposes, be assumed that the cows would consume about one-fourth more food than the oxen. Accordingly, in the Rothamsted estimates of the value of the manure obtained on the consumption of food for the production of milk, it is assumed that one-fourth more will be consumed by 1000 ℔ live-weight of cows than by the same weight of oxen; but the estimates of the amounts of the constituents of the food removed in the milk, or remaining for manure, are nevertheless reckoned per ton of each kind of food consumed, as in the case of those relating to feeding for the production of fattening increase. It may be added that the calculations of the amounts of the constituents in the milk are based on the same average composition of milk as is adopted in the construction of Table V. Thus the nitrogen is taken at 0·579 (=3·65 nitrogenous substance) per cent., the phosphoric acid at 0·2175 per cent., and the potash at 0·1875 per cent. in the milk.

Table VIII. shows in detail the estimate of the amount of nitrogen in one ton of each food, and in the milk produced from its consumption, on the assumption of an average yield of 10 quarts per head per day; also the

TABLE VIII. *Estimates of the Total or Original Manure-Value of Cattle Foods after Consumption by Cows for the Production of Milk. Valuations on the assumption of an average production by a herd of* 10 *quarts of milk per head per day.*

amount remaining for manure, the amount of ammonia corresponding to the nitrogen, and the value of the ammonia at 4d. per ℔. Similar particulars are also given in relation to the phosphoric acid and the potash consumed in the food, removed in the milk, and remaining for manure, &c. This table will serve as a sufficient illustration of the mode of estimating the *total or original* value of the manure, derived from the consumption of the different foods for the production of milk in the case supposed; that is, assuming an average yield of a herd of 10 quarts per head per day.

In Table IX. are given the results of similar detailed calculations of the *total or original* manure-value (as in Table VIII. for 10 quarts), on the alternative assumptions

of a yield of 6, 8, 12, and 14 quarts per head per day. For comparison there is also given, in the first column, the estimate of the *total or original* manure-value when the foods are consumed for the production of fattening increase.

So much for the plan and results of the estimations of *total or original* manure-value of the different foods, that is, deducting only the constituents removed in the milk, and reckoning the remainder at the prices at which they can be purchased in artificial manures. With a view to direct application to practice, however, it is necessary to estimate the *unexhausted manure-value* of the different foods, or what may be called their *compensation-value*, after they have been used for a series of years by the outgoing tenant and he has realized a certain portion of the manure-value in his increased crops. In the calculations for this purpose the rule is to deduct one-half of the *original manure-value* of the food used the last year, and one-third of the remainder each year to the eighth, in the case of all the more concentrated foods, and of the roots—in fact, of all the foods in the list excepting the hays and the straws. For these, which contain larger amounts of indigestible matter, and the constituents of which will be more slowly available to crops, two-thirds of the *original manure-value* is deducted for the last year, and only one-fifth from year to year to the eighth year back. The results of the estimates of *compensation-value* so made are given for the five yields of 6, 8, 10, 12, and 14 quarts of milk per head per day respectively in Lawes and Gilbert's paper[1] on the valuation of the manures obtained by the consumption of foods for the production of milk, which may be consulted for fuller details. It must, however, be borne in mind that when cows are fed in sheds or yards the manure is generally liable to greater losses than is the case with fattening oxen. The manure of the cow contains much more water in proportion to solid matter than that of the ox. Water will, besides, frequently be used for washing, and it may be that a good deal of the manure is washed into drains and lost. In the event, therefore, of a claim for compensation, the management and disposal of the manure requires the attention of the valuer. Indeed, the varying circumstances that will arise in practice must be carefully considered. Bearing these in mind, the estimates may be accepted as at any rate the best approximation to the truth that existing knowledge provides; and they should be found sufficient for the requirements of practical use. Obviously they will be more directly applicable in the case of cows feeding entirely on the foods enumerated in the list, and not depending largely on grass; but, even when the animals are partially grass-fed, the value of the manure derived from the additional dry food, or roots, may be estimated according to the scale given. The whole question is more fully dealt with under AGRICULTURE.

TABLE IX. *Comparison of the Estimates of Total or Original Manure-Value, when Foods are consumed for the Production of Fattening Increase, with those when the Food is consumed by Cows giving different Yields of Milk.*

## CHEESE AND CHEESE-MAKING.

For generations, perhaps for centuries, the question has been discussed as to why there should be so large a proportion of bad and inferior cheese and so small a proportion of really good cheese made in farmhouses throughout the land. That the result is not wholly due to skill and care, or to the absence of these qualities, on the part of the dairymaid may now be taken for granted. Instances might be quoted in which the most painstaking of dairymaids, in the cleanest of dairies, have failed to produce cheese of even second-rate quality and character, and yet others in which excellent cheese has been made under commonplace conditions as to skill and equipment, and with not much regard to cleanliness in the dairy. The explanation of what was so long a mystery has been found in the domain of ferments. It is now known that whilst various micro-organisms, which in many dairies have free access to the milk, have ruined an incalculable quantity of cheese—and of butter also—neither cheese nor butter of first-rate quality can be made without the aid of lactic acid bacilli. As an illustrative case, mention may be made of that of two most painstaking dairymaids who had tried in vain to make good cheese from the freshest of milk in the cleanest of dairies in North Lancashire. Advice to resort to the use of the ferment was acted upon, and the result was a revelation and a transformation, excellent prize-winning cheese being made from that time forward. By the addition of a "starter," in the form of a small quantity of sour milk, whey, or buttermilk, in an advanced stage of fermentation, the development of acidity in the main body of milk is accelerated. It has been ascertained that the starter is practically a culture of bacteria, which, if desired, may be obtained as a pure culture. Professor J. R. Campbell, as the result of recent experiments on pure cultures for Cheddar cheese-making, states[2] that (1) first-class Cheddar cheese can be made by using pure cultures of a lactic organism; (2) this organism abounds in all samples of sour milk and sour whey; (3) the use of a whey starter is attended with results equal in every respect to those obtained from a milk-starter. It is well within

[1] *Journ. Roy. Agric. Soc.*, 1898.
[2] *Trans. Highl. and Agric. Soc. Scot.*, 1899.

the power of any dairyman to prepare what is practically a pure culture of the same bacterium as is supplied from the laboratory. Moreover, the sour-whey starter used by some of the successful cheese-makers before the introduction of the American system is in effect a pure culture, from which it follows that these men had, by empirical methods, attained the same end as that to which bacteriological research subsequently led. Wherever a starter is necessary, the use of a culture practically pure is imperative, whether such culture be obtained from the laboratory or prepared by what may be called the "home-made starter." Pure cultures may be bought for a few shillings in the open market.

The factory-made cheese of Canada, the United States, and Australasia, which is so largely imported into the United Kingdom, is all of the Cheddar type. The factory system has made no headway in the original home of the Cheddar cheese in the West of England. The system was thus described in the *Journal* of the British Dairy Farmers' Association in 1889 by Mr R. J. Drummond:—

"In the year 1885 I was engaged as cheese instructor by the Ayrshire Dairy Association, to teach the Canadian system of Cheddar cheese-making. I commenced operations under many difficulties, being a total stranger to both the people and the country, and with this, the quantities of milk were very much less than I had been in the habit of handling. Instead of having the milk from 500 to 1000 cows, we had to operate with the milk from 25 to not over 60 cows.

"The system of cheese-making commonly practised in the county of Ayr at that time was what is commonly known as the Joseph Harding or English Cheddar system, which differs from the Canadian system in many details, and in one particular is essentially different, namely, the manner in which the necessary acidity in the milk is produced. In the old method a certain quantity of sour whey was added to the milk each day before adding the rennet, and I have no doubt in my own mind that this whey was often added when the milk was already acid enough, and the consequence was a spoiled cheese.

"Another objection to this system of adding sour whey was, should the stuff be out of condition one day, the same trouble was inoculated with the milk from day to day, and the result was sure to be great unevenness in the quality of the cheese. The utensils commonly in use were very different to anything I had ever seen before; instead of the oblong cheese vat with double casings, as is used by all the best makers at the present time, a tub, sometimes of tin and sometimes of wood, from 4 to 7 feet in diameter by about 30 inches deep, was universally in use. Instead of being able to heat the milk with warm water or steam, as is commonly done now, a large can of a capacity of from 20 to 30 gallons was filled with cold milk and placed in a common hot-water boiler, and heated sufficiently to bring the whole body of milk in the tub to the desired temperature for adding the rennet. I found that many mistakes were made in the quantity of rennet used, as scarcely any two makers used the same quantity to a given quantity of milk. Instead of having a graduated measure for measuring the rennet, a common tea-cup was used for this purpose, and I have found in some dairies as low as 3 oz. of rennet was used to 100 gallons of milk, where in others as high as 6½ oz. was used to the same quantity. This of itself would cause a difference in the quality of the cheese.

"Coagulation and breaking completed, the second heating was effected by dipping the whey from the curd into the can already mentioned, and heated to a temperature of 140° F., and returned to the curd, and thus the process was carried on till the desired temperature was reached. This mode of heating I considered very laborious and at the same time very unsatisfactory, as it is impossible to distribute the heat as evenly through the curd in this way as by heating either with hot water or steam. The other general features of the method do not differ from our own very materially, with the exception that in the old method the curd was allowed to mature in the bottom of the tub, where at the same stage we remove the curd from the vat to what we call a curd-cooler made with a sparred bottom, so as to allow the whey to separate from the curd during the maturing or ripening process. In regard to the quality of cheese on the one method compared with the other, I think that there was some cheese just as fine made in the old way as anything we can possibly make in the new, with one exception, and that is, that the cheese made according to the old method will not toast—instead of the casein melting down with the butter-fat, the two become separated, which is very much objected to by the consumer—and, with this, want of uniformity through the whole dairy. This is a very short and imperfect description of how the cheese was made at the time I came into Ayrshire; and I will now give a short description of the system that has been taught by myself for the past four years, and has been the means of bringing this county so prominently to the front as one of the best cheese-making counties in Britain.

"Our duty in this system of cheese-making begins the night before, in having the milk properly set and cooled according to the temperature of the atmosphere, so as to arrive at a given heat the next morning. Our object in this is to secure, at the time we wish to begin work in the morning, that degree of acidity or ripeness essential to the success of the whole operation. We cannot give any definite guide to makers how, or in what quantities, to set their milk, as the whole thing depends on the good judgment of the operator. If he finds that his milk works best at a temperature of 68° F. in the morning, his study the night before should tend toward such a result, and he will soon learn by experience how best to manage the milk in his own individual dairy. I have found in some dairies that the milk worked quite fast enough at a temperature of 64° in the morning, where in others the milk set in the same way would be very much out of condition by being too sweet, causing hours of delay before matured enough to add the rennet. Great care should be taken at this point, making sure that the milk is properly matured before the rennet is added, as impatience at this stage often causes hours of delay in the making of a cheese. I advise taking about six hours from the time the rennet is added till the curd is ready for salting, which means a six-hours process; if much longer than this, I have found by experience that it is impossible to obtain the best results. The cream should always be removed from the night's milk in the morning and heated to a temperature of about 84° before returning it to the vat. To do this properly and with safety, the cream should be heated by adding about two-thirds of warm milk as it comes from the cow to one-third of cream, and passed through the ordinary milk-strainers. If colouring matter is used, it should be added fifteen to twenty minutes before the rennet, so as to become thoroughly mingled with the milk before coagulation takes place.

"We use from 4 to 4½ oz. of Hansen's rennet extract to each 100 gallons of milk, at a temperature of 86° in spring and 84° in summer, or sufficient to coagulate milk firm enough to cut in about forty minutes when in a proper condition. In cutting, great care should be taken not to bruise the curd. I cut lengthwise, then across with perpendicular knife, then with horizontal knife the same way as the perpendicular, leaving the curd in small cubes about the size of ordinary peas. Stirring with the hands should begin immediately after cutting, and continue for ten to fifteen minutes prior to the application of heat. At this stage we use a rake instead of the hands for stirring the curd during the heating process, which lasts about one hour from time of beginning until the desired temperature of 100° or 102° is reached. After heating, the curd should be stirred another twenty minutes, so as to become properly firm before allowing it to settle. We like the curd to lie in the whey fully one hour after allowing it to settle before it is ready for drawing the whey, which is regulated altogether by the condition of the milk at the time the rennet is added. At the first indication of acid, the whey should be removed as quickly as possible. I think at this point lies the greatest secret of cheese-making—to know when to draw the whey.

"I depend entirely on the hot-iron test at this stage, as I consider it the most accurate and reliable guide known to determine when the proper acidity has been developed. To apply this test, take a piece of steel bar about 18 inches long by an inch wide and ¼ inch thick, and heat to a black heat: if the iron is too hot, it will burn the curd; if too cold, it will not stick; consequently it is a very simple matter to determine the proper heat. Take a small quantity of the curd from the vat and compress it tightly in the hand, so as to expel all the whey; press the curd against the iron, and when acid enough it will draw fine silky threads ¼ inch long. At this stage the curd should be removed to the curd-cooler as quickly as possible, and stirred till dry enough to allow it to mat, which generally takes from five to eight minutes. The curd is now allowed to stand in one end of the cooler for thirty minutes, when it is cut into pieces from 6 to 8 inches square and turned, and so on every half-hour until it is fit for milling. After removing the whey, a new acid makes its appearance in the body of the curd which seems to depend for its development upon the action of the air, and the presence of which experience has shown to be an essential element in the making of a cheese. This acid should be allowed to develop properly before the addition of salt. To determine when the curd is ready for salting, the hot-iron test is again resorted to; and when the curd will draw fine silky threads 1½ inch long, and at the same time have a soft velvety feel when pressed in the hand, the butter-fat will not separate with the whey from the curd. I generally advise using 1 ℔ of salt to 50 ℔ of curd, more or less, according to the condition of the curd. After salting, we let the curd lie fifteen minutes, so as to allow the salt to be thoroughly dissolved before pressing.

"In the pressing, care should be taken not to press the curd too severely at first, as you are apt to lose some of the butter-fat, and

with this I do not think that the whey will come away so freely by heavy pressing at first. We advise three days' pressing before cheese is taken to the curing-room. All cheese should have a bath in water at a temperature of 120° next morning after being made, so as to form a good skin to prevent cracking or chipping. The temperature of the curing-room should be kept as near 60° as possible at all seasons of the year, and I think it a good plan to ventilate while heating."

With regard to the hot-iron test for acidity, Mr F. J. Lloyd, in describing his investigations on behalf of the Bath and West of England Society, states that cheese-makers have long known that in both the manufacture and the ripening of cheese the acidity produced—known to the chemist as "lactic acid"—materially influences the results obtained, and that amongst other drawbacks to the test referred to is the uncertainty of the temperature of the iron itself. He gives an account,[1] however, of a chemical method involving the use of a standard solution of an alkali (soda), and of a substance termed an "indicator" (phenolphthalein), which changes colour according to whether a solution is acid or alkaline. The apparatus used with these reagents is called the acidimeter. The two stages in the manufacture of a Cheddar cheese most difficult to determine empirically are (1) when to stop stirring and to draw the whey, and (2) when to grind the curd. The introduction of the acidimeter has done away with these difficulties; and though the use of this apparatus is not actually a condition essential to the manufacture of a good cheese, it is to many makers a necessity and to all an advantage. By its use the cheese-maker can determine the acidity of the whey, and so decide when to draw the latter off, and will thus secure not only the proper development of acidity in the subsequent changes of cheese-making, but also materially diminish the time which the cheese takes to make. Furthermore, it has been proved that the acidity of the whey which drains from the curd when in the cooler is a sufficiently accurate guide to the condition of the curd before grinding; and by securing uniformity in this acidity the maker will also ensure uniformity in the quality and ripening properties of the cheese. Speaking generally, the acidity of the liquid from the press should never fall below 0·80 per cent. nor rise above 1·20 per cent., and the nearer it can be kept to 1·00 per cent. the better. Simultaneously, of course, strict attention must be paid to temperature, time, and every other factor which can be accurately determined. Analyses of large numbers of Cheddar cheeses manufactured in every month of the cheese-making season show the average composition of ripe specimens to be—water, 35·58 per cent.; fat, 31·33; casein, 29·12; mineral matter or ash, 3·97. It has been maintained that in the ripening of Cheddar cheese fat is formed out of the curd, but a comparison of analyses of ripe cheeses with analyses of the curd from which the cheeses were made affords no evidence that this is the case.

The quantity of milk required to make 1 ℔ of Cheddar cheese may be learnt from Table X., which shows the results obtained at the cheese school of the Bath and West of England Society in the two seasons of 1899 and 1900. The cheese was sold at an average age of ten to twelve weeks. In 1899 a total of 21,220 gallons of milk yielded 20,537 ℔ of saleable cheese, and in 1900, 31,808 gallons yielded 29,631 ℔. In the two years together 53,028 gallons yielded 50,168 ℔, which is equivalent to 1·05 gallon of milk to 1 ℔ of cheese. For practical purposes it may be taken that one gallon, or slightly over 10 ℔, of milk yields 1 ℔ of pressed cheese. The prices obtained are added as a matter of interest.

Cheshire cheese is largely made in the county from which it takes its name, and in adjoining districts. It is extensively consumed in Manchester and Liverpool, and other parts of the densely populated county of Lancaster.

TABLE X. *Quantities of Milk employed and of Cheese produced in the Manufacture of Cheddar Cheese.*

| When Made. | Milk. | Green Cheese. | Saleable Cheese. | Shrinkage. | Price. |

| Sept. and Oct. | 8943 | 9635 | 8666 | 10 per cent. | 66s. |

The following is a description of the making of Cheshire cheese:—

The evening's milk is set apart until the following morning, when the cream is skimmed off. The latter is poured into a pan which has been heated by being placed in the boiling water of a boiler. The new milk obtained early in the morning is poured into the vessel containing the previous evening's milk with the warmed cream, and the temperature of the mixture is brought to about 75° F. Into the vessel is introduced a piece of rennet, which has been kept in warm water since the preceding evening, and in which a little Spanish annatto (a quarter of an ounce is enough for a cheese of 60 ℔) is dissolved. (Marigolds, boiled in milk, are occasionally used for colouring cheese, to which they likewise impart a pleasant flavour. In winter, carrots scraped and boiled in milk, and afterwards strained, will produce a richer colour; but they should be used with moderation, on account of their taste.) The whole is now stirred together, and covered up warm for about an hour, or until it becomes curdled; it is then turned over with a bowl and broken very small. After standing a little time, the whey is drawn from it, and as soon as the curd becomes somewhat more solid it is cut into slices and turned over repeatedly, the better to press out the whey.

The curd is then removed from the tub, broken by hand or cut by a curd-breaker into small pieces, and put into a cheese vat, where it is strongly pressed both by hand and with weights, in order to extract the remaining whey. After this it is transferred to another vat, or into the same if it has in the meantime been well scalded, where a similar process of breaking and expressing is repeated, until all the whey is forced from it. The cheese is now turned into a third vat, previously warmed, with a cloth beneath it, and a thin hoop or binder put round the upper edge of the cheese and within the sides of the vat, the cheese itself being previously enclosed in a clean cloth, and its edges placed within the vat, before transfer to the cheese-oven. These various processes occupy about six hours, and eight more are requisite for pressing the cheese, under a weight of 14 or 15 cwt. The cheese during that time should be twice turned in the vat. Holes are bored in the vat which contains the cheese, and also in the cover of it, to facilitate the extraction of every drop of whey. The pressure being continued, the cheese is at length taken from the vat as a firm and solid mass.

On the following morning and evening it must be again turned and pressed; and also on the third day, about the middle of which it should be removed to the salting chamber, where the outside is well rubbed with salt, and a cloth binder passed round it which is not turned over the upper surface. The cheese is then placed in brine extending half-way up in a salting-tub, and the upper surface is thickly covered with salt. Here it remains for nearly a week, being turned twice in the day. It is then left to dry for two or three days, during which period it is turned once—being well salted at each turning—and cleaned every day. When taken from the brine it is put on the salting benches, with a wooden girth round it of nearly the thickness of the cheese, where it stands a few days, during which time it is again salted and turned every day. It is next washed and dried; and after remaining on the drying benches about seven days, it is once more washed in warm water with a brush, and wiped dry. In a couple of hours after this it is rubbed all over with sweet whey butter, which operation is afterwards frequently repeated; and, lastly, it

[1] *Report on Cheddar Cheese-Making*, London, 1899.

is deposited in the cheese- or store-room—which should be moderately warm and sheltered from the access of air, lest the cheese should crack—and turned every day, until it has become sufficiently hard and firm. These cheeses require to be kept a considerable time.

As a matter of fact, there are three different modes of cheese-making followed in Cheshire, known as the *early* ripening, the *medium* ripening, and the *late* ripening processes. There is also a method which produces a cheese that is permeated with "green mould" when ripe, called "Stilton Cheshire"; this, however, is confined to limited districts in the county. The early ripening method is generally followed in the spring of the year, until the middle or end of April; the medium process, from that time until late autumn, or until early in June, when the late ripening process is adopted and followed until the end of September, changing again to the medium process as the season advances. The late ripening process is not found to be suitable for spring or late autumn make. There is a decided difference between these several methods of making. In the early ripening system a larger quantity of rennet is used, more acidity is developed, and less pressure employed than in the other processes. In the medium ripening process a moderate amount of acidity is developed, to cause the natural drainage of the whey from the curd when under press. In the late ripening system, on the other hand, the development of acidity is prevented as far as possible, and the whey is got out of the curd by breaking down finer, using more heat, and skewering when under press. In the Stilton Cheshire process a larger quantity of rennet is used, and less pressure is employed, than in the medium or late ripening systems.

It is hardly possible to enunciate any general rules for the making of Stilton cheese, which differs from Cheddar and Cheshire in that it is not subjected to pressure. Mr J. Marshall Dugdale, in 1899, made a visit of inspection to the chief Leicestershire dairies where this cheese is produced, but in his report[1] he stated that every Stilton cheese-maker worked on his own lines, and that at no two dairies did he find the details all carried out in the same manner. There is a fair degree of uniformity up to the point when the curd is ladled into the straining-cloths, but at this stage, and in the treatment of the curd before salting, diversity sets in, several different methods being in successful use. Most of the cheese is made from two curds, the highly acid curd from the morning's milk being mixed with the comparatively sweet curd from the evening's milk. Opinion varies widely as to the degree of tightening of the straining-cloths. No test for acidity appears to be used, the amount of acidity being judged by the taste, feel, and smell of the curd. When the desired degree of acidity has developed, the curd is broken by hand to pieces the size of small walnuts, and salt is added at the rate of about 1 oz. to 4 ℔ of dry curd, or 1 oz. to 3½ ℔ of wet curd, care being taken not to get the curd pasty. If a maker has learnt how to rennet the milk properly, and how to secure the right amount of acidity at the time of hooping—that is, when the broken and salted curd is put into the wooden hoops which give the cheese its shape—he has acquired probably two of the most important details necessary to success. It was formerly the custom to add cream to the milk used for making Stilton cheese, but the more general practice now is to employ new milk alone, which yields a product apparently as excellent and mellow as that from enriched milk.

As a cheese matures or becomes fit for consumption, not only is there produced the characteristic flavour peculiar to the type of cheese concerned, but with all varieties, independently of the quality of flavours developed, a profound physical transformation of the casein occurs. In the course of this change the firm elastic curd "breaks down"—that is, becomes plastic, whilst chemically the insoluble casein is converted into various soluble decomposition products. These ripening phenomena—the production of flavour and the breaking down of the casein (that is, the formation of proper texture) —used to be regarded as different phases of the same process. As subsequently shown, however, these changes are not necessarily so closely correlated. The theories formerly advanced as explanatory of the ripening changes in cheese were suggestive rather than based upon experimental *data*, and it is only since 1896 that careful scientific studies of the problem have been made. Of the two existing theories, the one, which is essentially European, ascribes the ripening changes wholly to the action of living organisms—the bacteria present in the cheese. The other, which had its origin in the United States, asserts that there are digestive enzymes—that is, unorganized or soluble ferments—inherent in the milk itself that render the casein soluble. The supporters of the bacterial theory are ranged in two classes. The one, led by Duclaux, regards the breaking down of the casein as due to the action of liquefying bacteria (Tyrothrix forms). On the other hand, Von Freudenreich has ascribed these changes to the lactic-acid type of bacteria, which develop so luxuriantly in hard cheese like Cheddar.

With regard to the American theory, and in view of the important practical results obtained by Babcock and Russell at the Wisconsin experiment station, the following account[2] of their work is of interest, especially as the subject is of high practical importance. In 1897 they announced the discovery of an inherent enzyme in milk, which they named *galactase*, and which has the power of digesting the casein of milk and producing chemical decomposition products similar to those that normally occur in ripened cheese. The theory has been advanced by them that this enzyme is an important factor in the ripening changes; and as in their experiments bacterial action was excluded by the use of anæsthetic agents, they conclude that, so far as the breaking down of the casein is concerned, bacteria are not essential to this process. In formulating a theory of cheese-ripening, they have further pointed out the necessity of considering the action of rennet extract as a factor concerned in the curing changes. They have shown that the addition of increased quantities of rennet extract materially hastens the rate of ripening, and that this is due to the pepsin which is present in all commercial rennet extracts. They find it easily possible to differentiate between the proteolytic action—that is, the decomposing of proteids—of pepsin and galactase, in that the first-named enzyme is incapable of producing decomposition products lower than the peptones precipitated by tannin. They have shown that the increased solubility—the ripening changes—of the casein in cheese made with rennet is attributable solely to the products peculiar to peptic digestion. The addition of rennet extract or pepsin to fresh milk does not produce this change, unless the acidity of the milk is allowed to develop to a point which experience has shown to be the best adapted to the making of Cheddar cheese. The *rationale* of the empirical process of ripening the milk before the addition of the rennet is thus explained. In studying the properties of galactase it was further found that this enzyme, as well as those present in rennet extract, is operative at very low temperatures, even below freezing-point. When cheese made in the normal manner was kept at temperatures ranging from 25° to 45° F. for periods averaging from 8 to 18 months, it was found that the texture of the product simulated that of a perfectly ripened cheese, but that such cheese developed a very mild flavour in comparison with the normally-cured product. Subsequent storage at

[1] "The Practice of Stilton Cheese-Making," *Journ. Roy. Agric. Soc.*, 1899.

[2] *Experiment Station Record*, xii. 9. Washington, 1901.

somewhat higher temperatures gives to such cheese a flavour the intensity of which is determined by the duration of storage. This indicates that the breaking down of the casein and the production of the flavour peculiar to cheese are in a way independent of each other and may be independently controlled—a point of great economic importance in commercial practice. Although it is generally believed that cheese ripened at low temperatures is apt to develop a more or less bitter flavour, the flavours in the cases described were found to be practically perfect. Under these conditions of curing, bacterial activity is inoperative, and these experiments are held to furnish an independent proof of the enzyme theory.

Not only are these investigations of interest from the scientific standpoint, as throwing light on the obscure processes of cheese-curing, but from a practical point of view they open up a new field for commercial exploitation. The inability to control the temperature in the ordinary factory curing-room results in serious losses, on account of the poor and uneven quality of the product, and the consumption of cheese has been greatly lessened thereby. These conditions may all be avoided by this low-temperature curing process, and it is not improbable that the cheese industry may undergo important changes in methods of treatment. With the introduction of cold-storage curing, and the necessity of constructing centralized plant for this purpose, the cheese industry may perhaps come to be differentiated into the manufacture of the product in factories of relatively cheap construction, and the curing or ripening of the cheese in central curing stations. In this way not only would the losses which occur under present practices be obviated, but the improvement in the quality of the cured product would be more than sufficient to cover the cost of cold-storage curing.

The characteristics of typical specimens of the different kinds of English cheese may be briefly described. Cheddar cheese possesses the aroma and flavour of a nut—the so-called "nutty" flavour. It should melt in the mouth, and taste neither sweet nor acid. It is of flaky texture, neither hard nor crumbly, and is firm to the touch. It is early-ripening and, if not too much acid is developed in the making, long-keeping. Before all others it is a cosmopolitan cheese. Some cheeses are "plain," that is, they possess the natural paleness of the curd, but many are coloured with annatto—a practice that might be dispensed with. The average weight of a Cheddar cheese is about 70 ℔. Stilton cheese is popularly but erroneously supposed to be commonly made from morning's whole milk with evening's cream added, and to be a "double-cream" cheese. The texture is waxy, and a blue-green mould permeates the mass if well ripened; the flavour is suggestive of decay. The average weight of a Stilton is 15 ℔. Cheshire cheese has a fairly firm and uniform texture, neither flaky on the one hand nor waxy on the other; is of somewhat sharp and piquant flavour when fully ripe; and is often—at eighteen months old, when a well-made Cheshire cheese is at its best—permeated with a blue-green mould, which, as in the case of Stilton cheese, contributes a characteristic flavour which is much appreciated. Cheshire cheese is, like Cheddar, sometimes highly-coloured, but the practice is quite unnecessary; the weight is about 55 ℔. Gloucester cheese has a firm, somewhat soapy, texture and sweet flavour. Double Gloucester differs from single Gloucester only in size, the former usually weighing 26 to 30 ℔, and the latter 13 to 15 ℔. Leicester cheese is somewhat loose in texture, and mellow and moist when nicely ripened. Its flavour is "clean," sweet, and mild, and its aroma pleasant. To those who prefer a mild flavour in cheese, a perfect Leicester is perhaps the most attractive of all the so-called "hard" cheese; the average weight of such a cheese is about 35 ℔. Derby cheese in its best forms is much like Leicester, being "clean" in flavour and mellow. It is sometimes rather flaky in texture, and is slow-ripening and long-keeping if made on the old lines; the average weight is 25 ℔. Lancashire cheese, when well made and ripe, is loose in texture and is mellow; it has a piquant flavour. As a rule it ripens early and does not keep long. Dorset cheese—sometimes called "blue vinny" (or veiny)—is of firm texture, blue-moulded, and rather sharp-flavoured when fully ripe; it has a local popularity, and the best makes are rather like Stilton. Wensleydale cheese, a local product in North Yorkshire, is of fairly firm texture and mild flavour, and may almost be spread with a knife when ripe; the finest makes are equal to the best Stilton. Cotherstone cheese, also a Yorkshire product, is very much like Stilton, and commonly preferable to it. The blue-green mould develops, and the cheese is fairly mellow and moist, whereas many Stiltons are hard and dry. Wiltshire cheese, in the form of "Wilts truckles," may be described as small Cheddars, the weight being usually about 16 ℔. Caerphilly cheese is a thin, flat product, having the appearance of an undersized single Gloucester and weighing about 8 ℔; it has no very marked characteristics, but enters largely into local consumption amongst the mining population of Glamorganshire and Monmouthshire. Soft cheese of various kinds is made in many localities, beyond which its reputation scarcely extends. One of the oldest and best, somewhat resembling Camembert when well ripened, is the little "Slipcote," made on a small scale in the county of Rutland; it is a soft, mellow, moist cheese, its coat slipping off readily when the cheese is at its best for eating—hence the name. Cream cheese is likewise made in many districts, but nowhere to a great extent. A good cream cheese is fairly firm but mellow, with a slightly acid yet very attractive flavour. It is the simplest of all cheese to make—cream poured into a perforated box lined with loose muslin practically makes itself into cheese in a few days' time, and is usually ripe in a week.

In France the pressed varieties of cheese with hard rinds include Gruyère, Cantal, Roquefort, and Port Salut. The first-named, a pale yellow cheese full of holes of varying size, is made in Switzerland and in the Jura Mountains district in the east of France; whilst Cantal cheese, which is of lower quality, is a product of the midland districts, and is made barrel-shape. Roquefort cheese is made from the milk of ewes, which are kept chiefly as dairy animals in the department of Aveyron, and the cheese is cured in the natural mountain caves at the village of Roquefort. It is a small, rather soft, white cheese, abundantly veined with a greenish-blue mould, and weighs between 4 and 5 ℔. The Port-Salut is quite a modern cheese, which originated in the abbey of that name in Mayenne; it is a thin, flat cheese, of characteristic and not unattractive odour and flavour. The best known of the soft unpressed cheeses are Brie, Camembert, and Coulommiers, whilst Pont l'Evêque, Livarot, and other varieties are also made. After being shaped in moulds of various forms, these cheeses are laid on straw mats to cure, and when fit to eat they possess about the same consistency as butter. The Neufchâtel, Gervais, and Bondon cheeses are soft varieties intended to be eaten quite fresh, like cream cheese.

Of the varieties of cheese made in Switzerland, the best known is the Emmenthaler, which is about the size of a cart-wheel, and has a weight varying from 150 to 300 ℔. It is full of small holes of almost uniform size and very regularly distributed. In colour and flavour it is the same as Gruyère. The Edam and Gouda are the common cheeses of Holland. The Edam is spherical in shape, weighs from 3 to 4 ℔, and is usually dyed crimson on

the outside. The Gouda is a flat cheese with convex edges, and is of any weight up to 20 ℔. Of the two, the Edam has the finer flavour. Limburger is the leading German cheese, whilst other varieties are the Backstein and Munster; all are strong-smelling. Parmesan cheese is an Italian product, round and flat, about 5 inches thick, weighing from 60 to 80 ℔, and possessed of fine flavour. Gorgonzola cheese, so called from the Italian town of that name near Milan, is made in the Cheddar shape, and weighs from 20 to 40 ℔. When ripe it is permeated by a blue mould, and resembles in flavour, appearance, and consistency a rich old Stilton.

### Butter and Butter-Making.

As with cheese, so with butter, large quantities of the latter have been inferior not because the cream was poor in quality, but because the wrong kinds of bacteria had taken possession of the atmosphere in hundreds of dairies. The greatest if not the latest novelty in dairying in the last decade of the 19th century was the isolation of lactic acid bacilli, their cultivation in a suitable medium, and their employment in cream preparatory to churning. Used thus in butter-making, an excellent product results, provided cleanliness be scrupulously maintained. The culture repeats itself in the buttermilk, which in turn may be used again with marked success. Much fine butter, indeed, was made long before the bearing of bacteriological science upon the practice of dairying was recognized—made by using acid buttermilk from a previous churning.

In Denmark, which is, for its size, the greatest butter-producing country in the world, most of the butter is made with the aid of "starters," or artificial cultures which are employed in ripening the cream. Though the butter made by such cultures shows little if any superiority over a good sample made from cream ripened in the ordinary way,—that is, by keeping the cream at a fairly high temperature until it is ready for churning, when it must be cooled—it is claimed that the use of these cultures enables the butter-makers of Denmark to secure a much greater uniformity in the quality of their produce than would be possible if they depended upon the ripening of the cream through the influence of bacteria taken up in the usual way from the air.

Butter-making is an altogether simpler process than cheese-making, but success demands strict attention to sound principles, the observance of thorough cleanliness in every stage of the work, and the intelligent use of the thermometer. The following rules for butter-making, issued by the Royal Agricultural Society, sufficiently indicate the nature of the operation:—

Prepare churn, butter-worker, wooden hands, and sieve as follows:—(1) Rinse with cold water. (2) Scald with boiling water. (3) Rub thoroughly with salt. (4) Rinse with cold water.

*Always use a correct thermometer.*

The cream, when in the churn, to be at a temperature of 56° to 58° F. in summer and 60° to 62° F. in winter. The churn should never be more than half full. Churn at number of revolutions suggested by maker of churn. If none are given, *churn at* 40 *to* 45 *revolutions per minute.* Always churn slowly at first.

*Ventilate* the churn *freely* and frequently during churning, until no air rushes out when the vent is opened.

*Stop churning immediately* the butter comes. This can be ascertained by the sound; if in doubt, *look.*

The butter should now be like grains of mustard seed. Pour in a small quantity of cold water (1 pint of water to 2 quarts of cream) to harden the grains, and give a few more turns to the churn gently.

Draw off the buttermilk, giving plenty of time for draining. Use a straining-cloth placed over a hair-sieve, so as to prevent any loss, and wash the butter in the churn with plenty of cold water; then draw off the water, and repeat the process until the water comes off quite clear.

*To brine butter,* make a strong brine, 2 to 3 ℔ of salt to 1 gallon of water. Place straining-cloth over mouth of churn, pour in brine, put lid on churn, turn sharply half a dozen times, and leave for 10 to 15 minutes. Then lift the butter out of churn into sieve, turn butter out on worker, leave it a few minutes to drain, and work gently till all superfluous moisture is pressed out.

*To drysalt butter,* place butter on worker, let it drain 10 to 15 minutes, then work gently till all the butter comes together. Place it on the scales and weigh; then weigh salt, for slight salting, $\frac{1}{4}$ oz.; medium, $\frac{1}{2}$ oz.; heavy salting, $\frac{3}{4}$ oz. to the ℔ of butter. Roll butter out on worker and carefully sprinkle salt over the surface, a little at a time; roll up and repeat till all the salt is used.

*Never touch the butter with your hands.*

Well-made butter is firm and not greasy. It possesses a characteristic texture or "grain," in virtue of which it cuts clean with a knife and breaks with a granular fracture, like that of cast-iron. Theoretically, butter should consist of little else than fat, but in practice this degree of perfection is never attained. Usually the fat ranges from 83 to 88 per cent., whilst water is present to the extent of from 10 to 15 per cent.[1] There will also be from 0·2 to 0·8 per cent. of milk-sugar, and from 0·5 to 0·8 per cent. of casein. It is the casein which is the objectionable ingredient, and the presence of which is usually the cause of rancidity. In badly washed or badly worked butter, from which the buttermilk has not been properly removed, the proportion of casein, or curd, left in the product may be considerable, and such butter has only inferior keeping qualities. At the same time, the mistake may be made of overworking or of overwashing the butter, thereby depriving it of the delicacy of flavour which is one of its chief attractions as an article of consumption if eaten fresh. The object of washing with brine is that the small quantity of salt thus introduced shall act as a preservative and develop the flavour. Streaky butter may be due either to curd left in by imperfect washing, or to an uneven distribution of the salt.

### Equipment of the Dairy.

The improved form of milking-pail shown in Fig. 1 has rests or brackets, which the milker when seated on

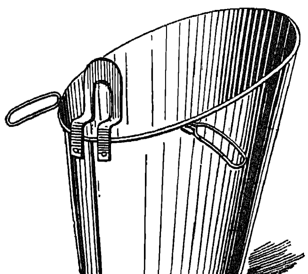

Fig. 1.—Milking Pail.

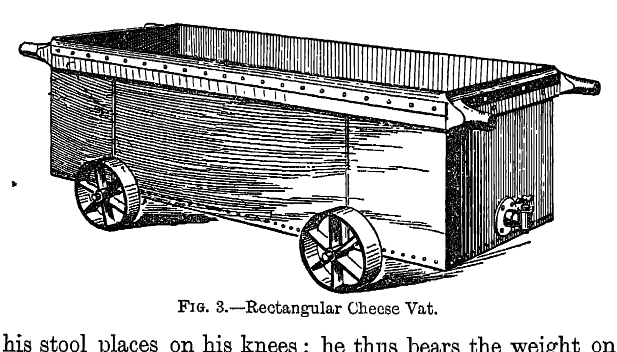

Fig. 3.—Rectangular Cheese Vat.

his stool places on his knees; he thus bears the weight on his thighs, and is entirely relieved of the strain involved

[1] Market butter is sometimes deliberately over-weighted with water, and a fraudulent profit is obtained by selling this extra moisture at the price of butter. In July 1901, therefore, a departmental committee was appointed to inquire into the matter (*vide infra*).

in gripping the can between the knees. The milk sieve or strainer (Fig. 2) is used to remove cow-hairs and any other mechanical impurity that may have fallen into the milk. A double straining surface is provided, the second being of very fine gauze placed vertically, so that the pressure of the milk does not force the dirt through; the strainer is easily washed. The cheese tub or vat receives the milk for cheese-making. The rectangular form shown in Fig. 3 is a Cheshire cheese-vat, for steam. The inner vat is of tinned steel, and the outer is of iron and is fitted with pipes for steam supply. Round cheese-tubs (Fig. 4) are made of strong sheets of steel, doubled tinned to render them lasting. They are fitted with a strong bottom hoop and bands round the sides, and can be double-jacketed for steam-heating if required. Curd-knives (Fig. 5) are used for cutting the coagulated mass into cubes in order to liberate the whey. They are made of fine steel, with sharp edges; there are also wire curd-breakers. The object of the curd-mill (Fig. 6) is to grind consolidated curd into small pieces, preparatory to salting and vatting; two spiked rollers work up to spiked breasts. Hoops, into which the curd is placed in order to acquire the shape of the cheese, are of wood or steel, the former being made of well-seasoned oak with iron bands (Fig. 7), the latter of tinned steel. The cheese is more easily removed

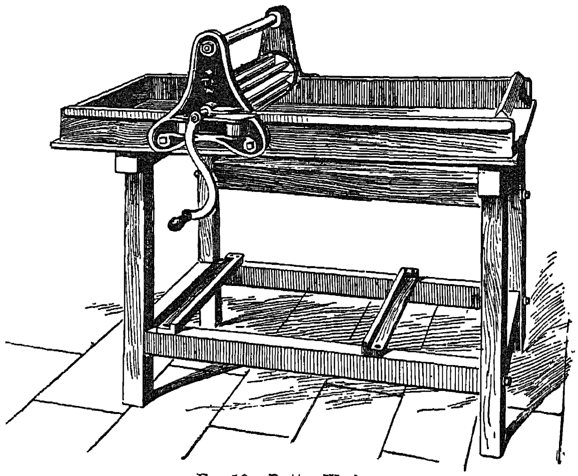

FIG. 16.—Butter Worker.

from the steel hoops, and they are readily cleaned. The cheese-press (Fig. 8) is used only for hard or "pressed" cheese, such as Cheddar. The arrangement is such that the pressure is continuous; in the case of soft cheese the curd is merely placed in moulds (Figs. 9 and 10) of the required shape, and then taken out to ripen, no pressure being applied. The cheese-room is fitted with easily-turned shelves, on which newly-made "pressed" cheeses are laid to ripen.

In the butter dairy, when the centrifugal separator is not used, milk is "set" for cream-raising in the milk-pan (Fig. 11), a shallow vessel of white porcelain, tinned steel, or enamelled iron. The skimming-dish or skimmer (Fig. 12), made of tin, is for collecting the cream from the surface of the milk, whence it is transferred to the cream-crock (Fig. 13), in which vessel the cream remains from one to three days, till it is required for churning. Many different kinds of churns are in use, and vary much in size, shape, and fittings; the one illustrated in Fig. 14 is a very good type of diaphragm churn. The butter-scoop (Fig. 15) is of wood, and is sometimes perforated; it is used for taking the butter out of the churn. The butter-worker (Fig. 16) is employed for consolidating newly-churned butter, pressing out superfluous water, and mixing in salt. More extended use, however, is now being made of the "Délaiteuse" butter-dryer, a centrifugal machine that rapidly extracts the moisture from the butter, and renders the butter-worker unnecessary, whilst the butter produced has a better grain. Scotch hands (Fig. 17), made of boxwood, are used for the lifting, moulding, and pressing of butter.

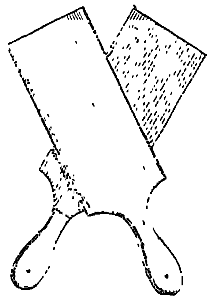

FIG. 17.—Scotch Hands.

In the centrifugal cream-separator the new milk is allowed to flow into a bowl, which is caused to rotate on its own axis several thousand times per minute. The heavier portion which makes up the watery part of the milk flies to the outer circumference of the bowl, whilst the lighter particles of butter-fat are forced to travel in an inner zone. By a simple mechanical arrangement the separated milk is forced out at one tube and the cream at another, and they are collected in distinct vessels. Separators are made of all sizes, from small machines dealing with 10 or 20 up to 100 gallons an hour, and worked by hand (Fig. 18), to large machines separating 150 to 440 gallons an hour, and worked by horse, steam, or other power (Fig. 19). Separation is found to be most effective at temperatures ranging in different machines from 80° to 98° F., though as high a temperature as 150° is sometimes employed. The most efficient separators remove nearly the whole of the butter-fat, the quantity of fat left in the separated milk falling in some cases to as low as 0·1 per cent. When cream is raised by the deep-setting method, from 0·2 to 0·4 per cent. of fat is left in the skim-milk; by the shallow-setting method from 0·3 to 0·5 per cent. of the fat is left behind. As a rule, therefore, "separated" milk is much poorer in fat than ordinary "skim" milk left by the cream-raising method in deep or shallow vessels.

The first continuous working separator was the invention of Dr de Laval. The more recent invention by Baron von Bechtolsheim of what are known as the Alfa discs, which are placed along the centre of the bowl of the separator, has much increased the separating capacity of the machines without adding to the power required. This has been of great assistance to dairy farmers by lessening the cost of the manufacture of butter, and thus enabling a large additional number of factories to be established in different parts of the world, particularly in Ireland, where these disc machines are very extensively used.

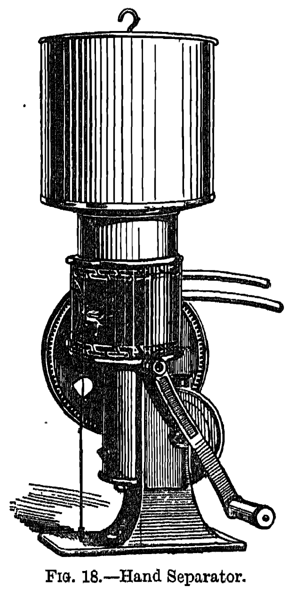

FIG. 18.—Hand Separator.

The pasteurizer—so named after the French chemist Pasteur — affords a means whereby at the outset the milk is maintained at a temperature of 170° to 180° F. for a period of eight or ten minutes. The object of this is to destroy the tubercle bacillus, if it should happen to exist in the milk, whilst incidentally the bacilli associated with several other diseases communicable through the medium of milk would also be killed if they were present. Discordant results have been recorded by experimenters who have attempted to kill tubercle bacilli in milk by heating the latter in open vessels, thereby permitting the formation of a scum

or "scalded layer" capable of protecting the tubercle bacilli, and enabling them to resist a higher temperature

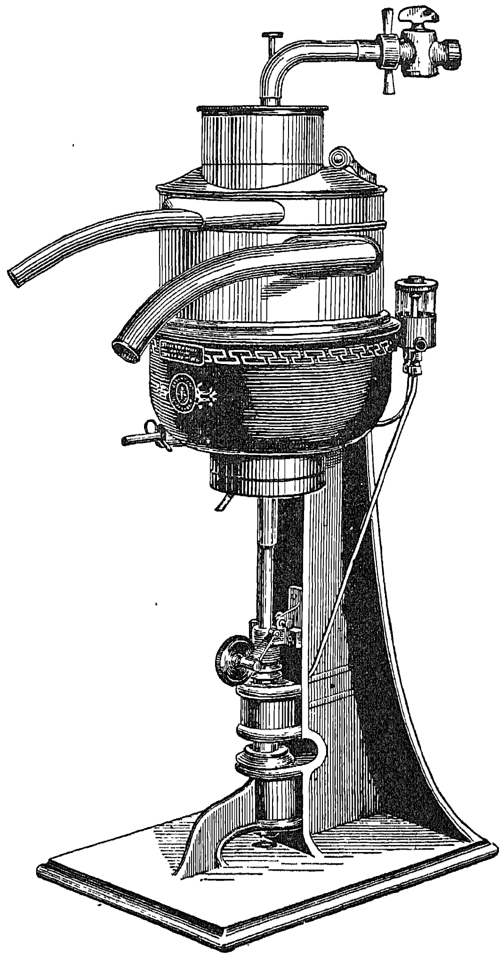

FIG. 19.—Power Separator.

than otherwise would be fatal to them. At a temperature not much above 150° F. milk begins to acquire the cooked flavour which is objectionable to many palates, whilst its "body" is so modified as to lessen its suitability for creaming purposes. Three factors really enter into effective pasteurization of milk, namely, (1) the temperature to which the milk is raised, (2) the length of time it is kept at that temperature, (3) the maintenance of a condition of mechanical agitation to prevent the formation of "scalded layer." Within limits, what a higher temperature will accomplish if maintained for a very short time may be effected by a lower temperature continued over a longer period. The investigation of the problem forms the subject of a paper[1] in the *17th Annual Report of the Wisconsin Agricultural Experiment Station*, 1900. The following are the results of the experiments:—

1. An exposure of tuberculous milk in a tightly closed commercial pasteurizer for a period of ten minutes destroyed in every case the tubercle bacillus, as determined by the inoculation of such heated milk into susceptible animals like guinea-pigs.
2. Where milk is exposed under conditions that would enable a pellicle or membrane to form on the surface, the tubercle organism is able to resist the action of heat at 140° F. (60° C.) for considerably longer periods of time.
3. Efficient pasteurization can be more readily accomplished in a closed receptacle such as is most frequently used in the commercial treatment of milk, than where the milk is heated in open bottles or open vats.
4. It is recommended, in order thoroughly to pasteurize milk so as to destroy any tubercle bacilli which it may contain, without in any way injuring its creaming properties or consistency, to heat the same in closed pasteurizers for a period of not less than twenty minutes at 140° F.

Under these conditions one may be certain that disease bacteria such as the tubercle bacillus will be destroyed without the milk or cream being injured in any way. For over a year this new standard has been in constant use in the Wisconsin University Creamery, and the results, from a purely practical point of view, reported a year earlier by Farrington and Russell,[2] have been abundantly confirmed.

Dairy engineers have solved the problem as to how large bodies of milk may be pasteurized, the difficulty of raising many hundreds or thousands of gallons of milk up to the required temperature, and maintaining it at that heat for a period of twenty minutes, having been successfully dealt with. The plant usually employed provides for the thorough filtration of the milk as it comes in from the farms, its rapid heating in a closed receiver and under mechanical agitation up to the desired temperature, its maintenance thereat for the requisite time, and finally its sudden reduction to the temperature of cold water through the agency of a refrigerator, to be next noticed.

Refrigerators are used for reducing the temperature of milk to that of cold water, whereby its keeping properties

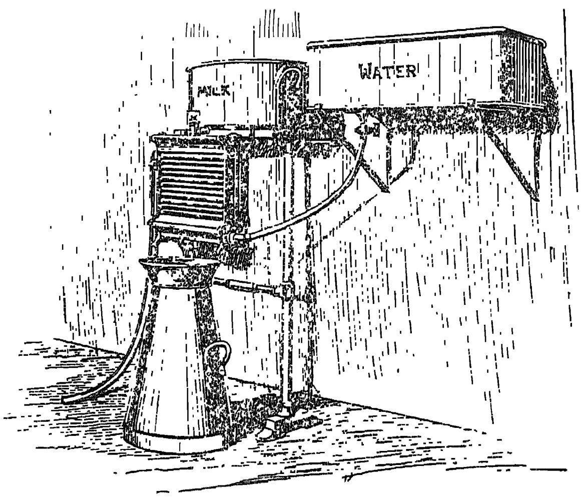

FIG. 20.—Refrigerator and Can.

are enhanced. The milk flows down the outside of the metal refrigerator (Fig. 20), which is corrugated in order to provide a larger cooling surface, whilst cold water circulates through the interior of the refrigerator. The conical vessel into which the milk is represented as flowing from the refrigerator in Fig. 20 is absurdly called a "milk-churn," whereas milk-can is a much more appropriate name. For very large quantities of milk, such as flow from a pasteurizing plant, cylindrical refrigerators (Fig. 21), made of tinned copper, are available; the cold water circulates inside, and the milk, flowing down the outside in a very thin sheet, is rapidly cooled from a temperature of

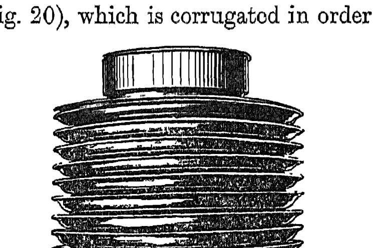

FIG. 21.—Cylindrical Cooler or Refrigerator.

[1] "Thermal Death-Point of Tubercle Bacilli, and Relation of same to Commercial Pasteurization of Milk." By H. L. Russell and E. G. Hastings.

[2] *16th Rept. Wis. Agric. Expt. Station*, 1899, p. 129.

140° F. or higher to 1° above the temperature of the water.

The fat test for milk was originally devised by Dr S. M. Babcock, of the Wisconsin Experiment Station, U.S.A. It combines the principle of centrifugal force with simple chemical action. Besides the machine itself and its graduated glass vessels, the only requirements are sulphuric acid of standard strength and warm water. The machines—often termed butyrometers—are commonly made to hold from two up to two dozen testers. After the tubes or testers have been charged, they are put in the apparatus, which is rapidly rotated as shown (Fig. 22); in a few minutes the test is complete, and with properly graduated vessels the percentage of fat can be read off at a glance. The butyrometer is extremely useful, alike for measuring periodically the fat-producing capacity of individual cows in a herd, for rapidly ascertaining the percentage of fat in milk delivered to factories and paying for such milk on the basis of quality, and for determining the richness in fat of milk supplied for the urban milk trade. Any intelligent person can soon learn to work the apparatus, but its efficiency is of course dependent upon the accuracy of the measuring vessels. To ensure this the Board of Agriculture have made arrangements with the National Physical Laboratory, Old Deer Park, Richmond, Surrey, to verify at a small fee the pipettes, measuring-glasses, and test-bottles used in connexion with the centrifugal butyrometer, which in recent years has been improved by Dr N. Gerber of Zurich.

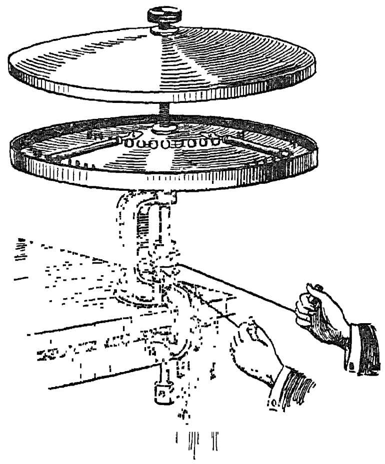

Fig. 22.—Butyrometer.

### Dairy Factories.

In connexion with co-operative cheese-making the merit of having founded the first "cheesery" or cheese factory is generally credited to Jesse Williams, who lived near Rome, in Oneida county, New York State. The system, therefore, was of American origin. Williams was a skilled cheese-maker, and the produce of his dairy sold so freely, at prices over the average, that he increased his output of cheese by adding to his own supply of milk other quantities which he obtained from his neighbours. His example was so widely followed that by the year 1866 there had been established close upon 500 cheese factories in New York State alone. In 1870 two co-operative cheeseries were at work in England, one in the town of Derby and one at Longford in the same county. There are now thousands of cheeseries in the United States and Canada, and also many "creameries," or butter factories, for the making of high-class butter.

The first creamery was that of Alanson Slaughter, and it was built near Wallkill, Orange county, New York State, in 1861, or ten years later than the first cheese factory; it dealt daily with the milk of 375 cows. Cheeseries and creameries would almost certainly have become more numerous than they are in England but for the rapidly-expanding urban trade in country milk. The development of each, indeed, has been contemporaneous since 1871, and they are found to work well in conjunction one with the other—that is to say, a factory is useful for converting surplus milk into cheese or butter when the milk trade is overstocked, whilst the trade affords a convenient avenue for the sale of milk whenever this may happen to be preferable to the making of cheese or butter. Extensive dealers in milk arrange for its conversion into cheese or butter, as the case may be, at such times as the milk market needs relief, and in this way a cheesery serves as a sort of economic safety-valve to the milk trade. The same cannot always be said of creameries, because the machine-skimmed milk of some of these establishments has been far too much used to the prejudice of the legitimate milk trade in urban districts. Be this as it may, the operations of cheeseries and creameries in conjunction with the milk trade have led to the diminution of home dairying. A rapidly-increasing population has maintained, and probably increased, its consumption of milk, which has obviously diminished the farmhouse production of cheese, and also of butter. The foreign competitor has been less successful with cheese than with butter, for he is unable to produce an article qualified to compete with the best that is made in Great Britain. In the case of butter, on the other hand, the imported article, though not ever surpassing the best home-made, is on the average much better, especially as regards uniformity of quality. Colonial and foreign producers, however, send into the British markets as a rule only the best of their butter, as they are aware that their inferior grades would but injure the reputation their products have acquired.

There are no official statistics concerning dairy factories in Great Britain, and such figures relating to Ireland were issued for the first time in 1901. The number of dairy factories in Ireland in 1900 was returned at 506, comprising 333 in Munster, 92 in Ulster, 52 in Leinster, and 29 in Connaught. Of the total number of factories, 495 received milk only, 9 milk and cream, and 2 cream only. As to ownership, 219 were joint-stock concerns, 190 were maintained by co-operative farmers, and 97 were proprietary. In the year ended 30th September 1900 these factories used up nearly 121 million gallons of milk, namely, 94 in Munster, 14 in Ulster, 7 in Leinster, and 6 in Connaught. The number of centrifugal cream-separators in the factories was 985, of which 889 were worked by steam, 79 by water, 9 by horse-power, and 8 by hand-power. The number of hands permanently employed was 3653, made up of 2976 in Munster, 279 in Leinster, 278 in Ulster, and 120 in Connaught. The year's output was returned at 401,490 cwt. of butter, 439 cwt. of cheese (made from whole milk), and 46,253 gallons of cream. In most cases the skim-milk is returned to the farmers. A return of the number of separators used in private establishments gave a total of 899, comprising 693 in Munster, 157 in Leinster, 39 in Ulster, and 10 in Connaught. In factories and private establishments together as many as 1884 separators were thus accounted for. Much of the factory butter would be sent into the markets of Great Britain, though some would no doubt be retained for local consumption. A great improvement in the quality of Irish butter has recently been noticeable in the exhibits entered at the London Dairy Show.

### Adulteration of Dairy Produce.

The Sale of Food and Drugs Act, 1899, which came into operation on January 1, 1900, contains several sections relating to the trade in dairy produce in the United Kingdom. Section 1 imposes penalties in the case of the importation of produce insufficiently marked, such as (a) margarine or margarine-cheese, except in packages conspicuously marked "Margarine" or "Margarine-cheese";

(*b*) adulterated or impoverished butter (other than margarine) or adulterated or impoverished milk or cream, except in packages or cans conspicuously marked with a name or description indicating that the butter or milk or cream has been so treated; (*c*) condensed separated or skimmed milk, except in tins or other receptacles which bear a label whereon the words "Machine-skimmed Milk" or "Skimmed Milk" are printed in large and legible type. For the purposes of this section an article of food is deemed to be adulterated or impoverished if it has been mixed with any other substance, or if any part of it has been abstracted, so as in either case to affect injuriously its quality, substance, or nature; provided that an article of food shall not be deemed to be adulterated by reason only of the addition of any preservative or colouring matter of such a nature and in such quantity as not to render the article injurious to health. Section 7 provides that every occupier of a manufactory of margarine or margarine-cheese, and every wholesale dealer in such substances, shall keep a register showing the quantity and destination of each consignment of such substances sent out from his manufactory or place of business, and this register shall be open to the inspection of any officer of the Board of Agriculture. Any such officer shall have power to enter at all reasonable times any such manufactory, and to inspect any process of manufacture therein, and to take samples for analysis. Section 8 is of much practical importance, as it limits the quantity of butter-fat which may be contained in margarine; it states that it shall be unlawful to manufacture, sell, expose for sale, or import any margarine the fat of which contains more than 10 per cent. of butter-fat, and every person who manufactures, sells, exposes for sale, or imports any margarine which contains more than that percentage shall be guilty of an offence under the Margarine Act, 1887. For the purposes of the Act *margarine-cheese* is defined as "any substance, whether compound or otherwise, which is prepared in imitation of cheese, and which contains fat not derived from milk"; whilst *cheese* is defined as "the substance usually known as cheese, containing no fat derived otherwise than from milk." The so-called "filled" cheese of American origin, in which the butter-fat of the milk is partially or wholly replaced by some other fat, would come under the head of "margarine-cheese." In making such cheese a cheap form of fat, usually of animal origin, but sometimes vegetable, is added to and incorporated with the skim-milk, and thus takes the place previously occupied by the genuine butter-fat. The Act is regarded by some as defective in that it does not prohibit the artificial colouring of margarine to imitate butter.

In connexion with this Act a departmental committee was appointed in 1900 "to inquire and report as to what regulations, if any, may with advantage be made by the Board of Agriculture under section 4 of the Sale of Food and Drugs Act, 1899, for determining what deficiency in any of the normal constituents of genuine milk or cream, or what addition of extraneous matter or proportion of water, in any sample of milk (including condensed milk) or cream, shall for the purposes of the Sale of Food and Drugs Acts, 1875 to 1899, raise a presumption, until the contrary is proved, that the milk or cream is not genuine." Much evidence of the highest interest to dairy farmers was taken, and subsequently published as a Blue-Book (Cd. 484). The report of the committee (Cd. 491) included the following "recommendations," which were signed by all the members excepting one:—

I. That regulations under section 4 of the Food and Drugs Act, 1899, be made by the Board of Agriculture with respect to milk (including condensed milk) and cream.

II. (*a*) That in the case of any milk (other than skimmed, separated, or condensed milk) the total milk-solids in which on being dried at 100° C. do not amount to 12 per cent. a presumption shall be raised, until the contrary is proved, that the milk is deficient in the normal constituents of genuine milk.

(*b*) That any milk (other than skimmed, separated, or condensed milk) the total milk-solids in which are less than 12 per cent., and in which the amount of milk-fat is less than 3·25 per cent., shall be deemed to be so deficient in milk-fat as to raise a presumption, until the contrary is proved, that it has been mixed with separated milk or water, or that some portion of its normal content of milk-fat has been removed. In calculating the percentage amount of deficiency of fat the analyst shall have regard to the above-named limit of 3·25 per cent. of milk-fat.

(*c*) That any milk (other than skimmed, separated, or condensed milk) the total milk-solids in which are less than 12 per cent., and in which the amount of non-fatty milk-solids is less than 8·5 per cent., shall be deemed to be so deficient in normal constituents as to raise a presumption, until the contrary is proved, that it has been mixed with water. In calculating the percentage amount of admixed water the analyst shall have regard to the above-named limit of 8·5 per cent. of non-fatty milk-solids, and shall further take into account the extent to which the milk-fat may exceed 3·25 per cent.

III. That the artificial thickening of cream by any addition of gelatin or other substance shall raise a presumption that the cream is not genuine.

IV. That any skimmed or separated milk in which the total milk-solids are less than 9 per cent. shall be deemed to be so deficient in normal constituents as to raise a presumption, until the contrary is proved, that it has been mixed with water.

V. That any condensed milk (other than that labelled "machine-skimmed milk" or "skimmed milk," in conformity with section 11 of the Food and Drugs Act, 1899) in which either the amount of milk-fat is less than 10 per cent., or the amount of non-fatty milk-solids is less than 25 per cent., shall be deemed to be so deficient in some of the normal constituents of milk as to raise a presumption, until the contrary is proved, that it is not genuine.

The committee further submitted the following expressions of opinion on points raised before them in evidence:—

(*a*) That it is desirable to call the attention of those engaged in the administration of the Food and Drugs Acts to the necessity of adopting effective measures to prevent any addition of water, separated or condensed milk, or other extraneous matter, for the purpose of reducing the quality of genuine milk to any limits fixed by regulation of the Board of Agriculture.

(*b*) That it is desirable that steps should be taken with the view of identifying or "ear-marking" separated milk by the addition of some suitable and innocuous substance, and by the adoption of procedure similar to that provided by section 7 of the Food and Drugs Act, 1899, in regard to margarine.

(*c*) That it is desirable that, so far as may be found practicable, the procedure adopted in collecting, forwarding, and retaining pending examination, samples of milk (including condensed milk) and cream under the Food and Drugs Acts should be uniform.

(*d*) That it is desirable that, so far as may be found practicable, the methods of analysis used in the examination of samples of milk (including condensed milk) or cream taken under the Food and Drugs Acts should be uniform.

(*e*) That it is desirable in the case of condensed milk (other than that labelled "machine-skimmed milk" or "skimmed milk," in conformity with section 11 of the Food and Drugs Act, 1899) that the label should state the amount of dilution required to make the proportion of milk-fat equal to that found in uncondensed milk containing not less than 3·25 per cent. of milk-fat.

(*f*) That it is desirable in the case of condensed whole milk to limit, and in the case of condensed machine-skimmed milk to exclude, the addition of sugar.

(*g*) That the official standardizing of the measuring vessels commercially used in the testing of milk is desirable.

In the minority report, signed by Mr Geo. Barham, the most important clauses are the following:—

(*a*) That in the case of any milk (other than skimmed, separated, or condensed milk) the total milk-solids in which are less

than 11·75 per cent., and in which, during the months of July to February inclusive, the amount of milk-fat is less than 3 per cent., and in the case of any milk which during the months of March to June inclusive shall fall below the above-named limit for total solids, and at the same time shall contain less than 2·75 per cent. of fat, it shall be deemed that such milk is so deficient in its normal constituent of fat as to raise a presumption, for the purposes of the Sale of Food and Drugs Acts, 1875 to 1899, until the contrary is proved, that the milk is not genuine.

(b) That any milk (other than skimmed, separated, or condensed milk) the total milk-solids in which are less than 11·75 per cent., and in which the amount of non-fatty solids is less than 8·5 per cent., shall be deemed to be so deficient in its normal constituents as to raise a presumption, for the purposes of the Sale of Food and Drugs Acts, 1875 to 1899, until the contrary is proved, that the milk is not genuine. In calculating the amount of the deficiency the analyst shall take into account the extent to which the milk-fat exceeds the limits above named.

(c) That any skimmed or separated milk in which the total milk-solids are less than 8·75 per cent. shall be deemed to be so deficient in its normal constituents as to raise a presumption, for the purpose of the Sale of Food and Drugs Acts, 1875 to 1899, until the contrary is proved, that the milk is not genuine.

Much controversy arose out of the publication of these reports, the opinion most freely expressed being that the standard recommended in the majority report was too high. The difficulty of the problem is illustrated by, for example, the diverse legal standards for milk that prevail in the United States, where the prescribed percentage of fat in fresh cows' milk ranges from 2·5 in Rhode Island to 3·5 in Georgia and Minnesota, and 3·7 (in the winter months) in Massachusetts, and the prescribed total solids range from 12 in several states (11·5 in Ohio during May and June) up to 13 in others. Standards are recognized in 21 of the states, but the remaining states have no laws prescribing standards for dairy products. That the public discussion of the reports of the committee was effective is shown by the following regulations which appeared in the *London Gazette* on 6th August 1901, and fixed the limit of fat at 3 per cent:—

The Board of Agriculture, in exercise of the powers conferred on them by section 4 of the Sale of Food and Drugs Act, 1899, do hereby make the following regulations:—

1. Where a sample of milk (not being milk sold as skimmed, or separated, or condensed milk) contains less than 3 per cent. of milk-fat, it shall be presumed for the purposes of the Sale of Food and Drugs Acts, 1875 to 1899, until the contrary is proved, that the milk is not genuine, by reason of the abstraction therefrom of milk-fat, or the addition thereto of water.
2. Where a sample of milk (not being milk sold as skimmed, or separated, or condensed milk) contains less than 8·5 per cent. of milk-solids other than milk-fat, it shall be presumed for the purposes of the Sale of Food and Drugs Acts, 1875 to 1899, until the contrary is proved, that the milk is not genuine, by reason of the abstraction therefrom of milk-solids other than milk-fat, or the addition thereto of water.
3. Where a sample of skimmed or separated milk (not being condensed milk) contains less than 9 per cent. of milk-solids, it shall be presumed for the purposes of the Sale of Food and Drugs Acts, 1875 to 1899, until the contrary is proved, that the milk is not genuine, by reason of the abstraction therefrom of milk-solids other than milk-fat, or the addition thereto of water.
4. These regulations shall extend to Great Britain.
5. These regulations shall come into operation on 1st September 1901.
6. These regulations may be cited as the Sale of Milk Regulations, 1901.

In July 1901 another departmental committee was appointed by the Board of Agriculture to inquire and report as to what regulations, if any, may with advantage be made under section 4 of the Sale of Food and Drugs Act, 1899, for determining what deficiency in any of the normal constituents of butter, or what addition of extraneous matter, or proportion of water in any sample of butter shall, for the purpose of the Sale of Food and Drugs Acts, raise a presumption, until the contrary is proved, that the butter is not genuine. As bearing upon this point reference may be made to a report of the Dairy Division of the United States Department of Agriculture on experimental exports of butter, in the appendix to which are recorded the results of the analyses of many samples of butter of varied origin. First, as to American butters, 19 samples were analysed in Wisconsin, 17 in Iowa, 5 in Minnesota, and 2 in Vermont, at the respective experiment stations of the states named. The amount of moisture throughout was low, and the quantity of fat correspondingly high. In no case was there more than 15 per cent. of water, and only 4 samples contained more than 14 per cent. On the other hand, 11 samples had less than 10 per cent., the lowest being a pasteurized butter from Ames, Iowa, with only 6·72 per cent. of water. The average amount of water in the total 43 samples was 11·24 per cent. The fat varies almost inversely as the water, small quantities of curd and ash having to be allowed for. The largest quantity of fat was 91·23 per cent. in the sample containing only 6·72 per cent. of water. The lowest proportion of fat was 80·18 per cent., whilst the average of all the samples shows 85·9 per cent., which is regarded as a good market standard. The curd varied from 0·55 to 1·7 per cent., with an average of 0·98. This small amount indicates superior keeping qualities. Theoretically there should be no curd present, but this degree of perfection is never attained in practice. It was desired to have the butter contain about 2½ per cent. of salt, but the quantity of ash in the 43 samples ranged from 0·83 to 4·79 per cent., the average being 1·88. Analyses made at Washington of butters other than American showed a general average of 13·22 per cent. of water over 28 samples representing 14 countries. The lowest were 10·25 per cent. in a Canadian butter and 10·38 in an Australian sample. The highest was 19·1 per cent. in an Irish butter, which also contained the remarkably large quantity of 8·28 per cent. of salt. Three samples of Danish butter contained 12·65, 14·27, and 15·14 per cent. respectively of water. French and Italian unsalted butter included, the former 15·46 and the latter 14·41 per cent. of water, and yet appeared to be unusually dry. In 7 samples of Irish butters the percentages of water ranged from 11·48 to 19·1. Of the 28 foreign butters 15 were found to contain preservatives. All 5 samples from Australia, the 2 from France, the single ones from Italy, New Zealand, Argentina, and England, and 4 out of the 7 from Ireland, contained boric acid.

### The Milk Trade.

The term "milk trade" has come to signify the great traffic in country milk for the supply of dwellers in urban districts. Prior to 1860 this traffic was comparatively small, or in its infancy. Thirty years earlier it could not have been brought into existence, for it is an outcome of the great network of railways which was spread over the face of the country in the latter half of the 19th century. It affords an instructive illustration of the process of commercial evolution which has been fostered by the vast increase of urban population within the period indicated. It is a tribute to the spirit of sanitary reform which—as an example in one special direction—has brought about the disestablishment of urban cow sheds and the consequent demand for milk produced in the shires. London, in fact, is now being regularly supplied with fresh milk from places anywhere within 150 miles, and the milk traffic on the railways, not only to London but to other great centres, is an important item. A factor in the development of the milk trade must no doubt be sought in the outbreak of cattle plague in 1865, for it was then that the dairymen of the metropolis were compelled to seek milk all over England, and the capillary refrigerator being invented

soon after, the production of milk has remained ever since in the hands of dairymen living mainly at a distance from the towns supplied.

This great change in country dairying, involving the continuous export of enormous quantities of milk from the farms, has been accompanied by subsidiary changes in the management of dairy farms, and has necessitated the extensive purchase of feeding-stuffs for the production of milk, especially in winter time. It is probable that, in this way, a gradual improvement of the soil on such farms has been effected, and the corn-growing soils of distant countries are adding to the store of fertility of soils in the British Isles. Country roads, exposed to the wear and tear of a comparatively new traffic, are lively at morn and eve with the rattle of vehicles conveying fresh milk from the farms to the railway stations. Most of these changes were brought about within the limits of the last third of the 19th century.

In the case of London, the daily supply of a perishable article such as milk, which must be delivered to the consumer within a few hours of its production, to a population of five millions, is an undertaking of very great magnitude, especially when it is considered that only a comparatively minute proportion of the supply is produced in the metropolitan area itself. To meet the demand of the London consumer some 5000 dairies proper exist, as well as a large number of businesses where milk is sold in conjunction with other commodities. It has been computed that some 12,000 traders are engaged in the business of milk-selling in the metropolis, and the number of persons employed in its distribution, &c., cannot be fewer than 25,000. The amount of capital involved is very great, and it may be mentioned that the paid-up capital of six of the principal distributing and retail dairy companies amounts to upwards of one million sterling. The most significant feature in connexion with the milk supply of the metropolis at the beginning of the 20th century is the gradual extinction of the town "cowkeeper"—the retailer who produces the milk he sells. The facilities afforded by the railway companies, the favourable rates which have been secured for the transport of milk, and the more enlightened methods of its treatment after production, have made it possible for milk produced under more favourable conditions to be brought from considerable distances and delivered to the retailer at a price lower than that at which it has been possible to produce it in the metropolis itself. As a result, the number of milk cows in the county of London diminished from 10,000 in 1889 to 5144 in 1900, the latter, on an estimated production of 700 gallons per cow—the average production of stall-fed town cows—representing a yearly milk yield of 3,600,000 gallons. How small a proportion this is of the total supply will be gathered from the fact that the annual quantity of milk delivered in London on the Great Western line amounts to some 11,000,000 gallons, whilst the London and North-Western Railway delivers 9,000,000, and the Midland Railway at St Pancras 5,000,000, and at others of its London stations about 1,000,000, making 6,000,000 in all. The London and South-Western Railway brings upwards of 8,000,000 gallons to London, a quantity of 7,500,000 gallons is carried by the Great Northern Railway, and the Great Eastern Railway is responsible for 7,000,000. The London, Brighton, and South Coast Railway delivers 1,000,000 gallons, and the South-Eastern and Chatham and the London and Tilbury Railways carry approximately 1,000,000 gallons between them. A large quantity of milk is also carried in by local lines from farms in the vicinity of London and delivered at the local stations, and some is now brought by the Great Central Railway, which has recently obtained an entry into London. In addition to this, milk is taken into London by carts from farms in the neighbourhood of the metropolis. A computation of the total milk supply of the metropolis reveals a quantity approximating to 60,000,000 gallons per annum, or rather more than a million gallons per week, which, taking 500 gallons as the average yearly production of the cows contributing to this supply, represents the yield of at least 120,000 cows. The growth of the supply of country milk to London is seen from the figures given by Mr George Barham, chairman of the Express Dairy Co. Limited, in an article on "The Milk Trade" contributed to Professor Sheldon's work on *The Farm and Dairy*. The quantities carried by the respective railways in 1889 are therein stated in gallons as :—Great Western, 9,000,000; London and North-Western, 7,000,000; Midland, 7,000,000; London and South-Western, 6,000,000; Great Northern, 3,000,000; Great Eastern, 3,000,000; the southern lines, 2,000,000. The increase, therefore, during the past twelve years on these lines amounts to no less than 13,500,000 gallons per annum, or 36 per cent. The diminished production in the metropolis itself amounts approximately to only 3,000,000 gallons, and it follows, therefore, that the consumption has largely increased.

Previous to 1864 it was only possible to bring milk into London from short distances, but the introduction of the refrigerator has enabled milk to be brought from places as far removed from the metropolis as North Staffordshire, and it has even been received from Scotland. Practically the whole of the milk supplied to the metropolis is produced in England. Attempts have been made to introduce foreign milk during recent years, and in 1898 a company was formed to promote the sale of fresh milk from Normandy, but the enterprise did not succeed. The trade has shown signs of reviving since, owing probably to the increased cost of the home produced article, and during the winter season of 1900–1901 the largest quantity received into the kingdom in one week amounted to 10,000 gallons. Of recent years a large demand has sprung up for sterilized milk in bottles, and a considerable trade is also done in humanized milk, which is a milk preparation approximating in its chemical composition to human milk.

Estimating the average yield of milk of each country cow at 500 gallons per annum, and assuming an average of 28 cows to each farm, as many as 4300 farmers are engaged in supplying London with milk; allotting ten cows to each milker, it needs 12 battalions of 1000 men each for this work alone. Some 3500 horses are required to convey the milk from the farms to the country railway stations. The chief sources of supply are in the counties of Derby, Stafford, Leicester, Northampton, Notts, Warwick, Bucks, Oxford, Gloucester, Berks, Wilts, Hants, Dorset, Essex, and Cambridge. It is not entirely owing to the railways that London's enormous supply of milk has been rendered possible, for the milk must still have been produced in the immediate neighbourhood of the metropolis had not the method of reducing the temperature of the product by means of the refrigerator been devised. There are probably 5700 horses engaged in the delivery of milk in London, and more people are employed in this work than in milking the cows. One of the great difficulties the London dairyman has to contend with, and a cause of frequent anxiety to him, is associated with the rise and fall of the thermometer, for a movement to the extent of ten degrees one way or the other may diminish or increase the supply in an inverse ratio to the demand. Thus, at periods of extreme cold, the cows shrink in their yield of milk, while from the same cause the Londoner is demanding more, in an extra cup of coffee, &c. Again, at periods of extreme heat, which has the same effect on the

cow's production as extreme cold, the customer also demands an increased quantity of milk. Ten degrees fall of temperature in the summer will result in a lessened demand and an enlarged supply—to such an extent, indeed, that a single firm has been known to have had returned by its carriers some 600 gallons in one day. In such cases the cream separator is capable of rendering invaluable assistance. To make cheese in London in large quantities and at uncertain intervals has been found to be impracticable, whilst to set for cream a great bulk of milk is almost equally so. But now a considerable portion of what would otherwise be lost is saved by passing the milk through separators, and churning the cream into butter.

Previous to the enormous development of the urban trade in country milk, dairy farms were in the main self-sustaining in the matter of manures and feeding-stuffs, and the cropping of arable land was governed by routine. To-day, on the contrary, many dairy farms are run at high pressure by the help of purchased materials,—corn, cake, and manure,—and the land is cropped regardless of routine and independent of courses. Such crops, moreover, are grown—white straw crops, green crops, root crops—as are deemed likely to be most needed at the time when they are ready. Green crops,—"soiling" crops, as they are termed in North America,—consisting largely of vetches or tares (held up by stalks of oat plants grown amongst them), cabbages, and in some districts green maize, are used to supplement the failing grass-lands at the fall of the year, and root crops, especially mangel, are advantageously grown for the same purpose. For winter feeding the farm is made to yield what it will in the shape of meadow and clover hay, and of course root crops of the several kinds. This provision is supplemented by the purchase of, for example, brewers' grains as a bulky food, and of oilcake and corn of many sorts as concentrated food.

## Home Output, Imports, and Exports of Dairy Produce.

Whilst the quantity of imported butter and cheese consumed in the United Kingdom from year to year can be arrived at with a tolerable degree of accuracy, it is more difficult to form an estimate of the amounts of these articles annually produced at home. Various attempts have, however, from time to time been made by competent authorities to arrive approximately at the annual output of milk, butter, and cheese in the United Kingdom, and the results have been brought down to date by Messrs W. Weddel & Co. in their annual *Dairy Produce Review* (1899–1900), from which Table XI. is quoted. It shows the estimates for each of the ten years 1890 to 1899, the numbers in the second column of "cows and heifers in milk or in calf" being identical with those officially recorded in the agricultural returns. In thus estimating the quantity of milk, butter, and cheese produced within the United Kingdom, the "average milking life" of a cow is taken to be four years, from which it follows that on the average one-fourth of the total herd has to be renewed every year by heifers with their first calf. This leaves 75 per cent. of the total herd giving milk throughout the year. Each cow of this 75 per cent. is estimated as yielding 49 cwt., or 531 gallons of milk annually. It is assumed that 15 per cent. of the total milk yield is used for the calf, 32 per cent. utilized for butter-making, 20 per cent. for cheese-making, and the remaining 33 per cent. consumed in the household as fresh milk. A ton of milk is estimated to produce 80 ℔ of butter or 220 ℔ of cheese. A gallon of milk weighs 10·33 ℔ ($10\frac{1}{3}$ ℔). The probable effects of each season upon the production have been taken into consideration in making these estimates, and it will be noticed that owing to the terrible drought of 1893 a reduction of 9 per cent. is made from the average. Accept-

Table XI. *Estimated Annual Production of Milk, Butter, and Cheese in the United Kingdom for the Ten Years ended* 31st *December* 1899.

| 1894 | 3,925,486 | 101·2 | 2,944,115 | +6·3 | 7,667,505 | 87,628 | 150,611 |
| 1895 | 3,937,590 | 100·5 | 2,953,193 | -3·5 | 6,982,087 | 79,652 | 137,148 |
| 1896 | 3,958,762 | 100 0 | 2,969,387 | -4 0 | 6,983,999 | 79,817 | 130,000 |
| 1897 | 3,984,167 | 99·7 | 2,988,126 | +3 1 | 7,547,856 | 86,261 | 148,200 |
| 1898 | 4,035,501 | 100 0 | 3,025,526 | +3·2 | 7,645,105 | 87,372 | 150,171 |
| 1899 | 4,133,249 | 101 9 | 3,099,937 | -3·5 | 7,329,027 | 83,760 | 130,020 |
| 10 *Years' Average* | 4,018,318 | 103·0 | 3,013,660 | -0·7 | 7,906,874 | 83,992 | 141,412 |

ing these estimates with due reservation,[1] it is seen that the annual production of milk varied in the decade to the extent of nearly a million tons, the exact difference between the maximum of 7,667,505 tons in 1895 and the minimum of 6,712,004 tons in 1894 being 955,501 tons. The decennial averages are 7,906,874 tons of milk, 83,992 tons of butter, and 141,412 tons of cheese.

Table XII. furnishes an estimate of the total consumption of butter in the United Kingdom in each of the years 1891 to 1900. Whilst the estimated home production did not vary greatly from year to year, the imports from colonial and foreign sources underwent almost continuous increase. The ten years' average indicates 37·6 per cent. home-made, 7·3 per cent imported colonial, and 55·1 per cent. imported foreign butter. But whereas at the beginning of the decade the proportions were 45·4 per cent. home-made, 1·5 per cent. colonial, and 53·2 per cent. foreign, at the end the percentages were 32·8, 14·7, and 52·5 respectively. It thus appears that whilst the United Kingdom was able in 1891 to furnish nearly half of its requirements (45·4 per cent.), by 1900 it was unable to supply more than one-third (32·8 per cent.).

The rapid headway which colonial butter is making in

[1] A special committee appointed by the council of the Royal Statistical Society commenced in 1901 an inquiry into the home production of milk and meat in the United Kingdom.

British markets is shown by the fact that for the five years ended 30th June 1900 the import had grown from 12,949 tons to 37,534 tons per annum, or an increase of 24,585 tons. It is during the mid-winter months that the colonial butter from Australasia arrives on the British markets, while that from Canada begins to arrive in July, and virtually ceases in the following January. The bulk of the Canadian butter reaches British markets during August, September, and October; the bulk of the Australasian in December, January, and February.

It appears to be demonstrated by the experience of the last decade of the 19th century that the United Kingdom is quite unable to turn out sufficient dairy produce to supply its own population. In the year ended 30th June 1891 the total import of butter was 102,500 tons, and for the year ended 30th June 1900 it was 170,700 tons, which shows an annual average increase in the decade of 6800 tons. This growth was on the whole very uniform, any disturbance in its regularity being attributable more to the deficient seasons in the colonies and foreign countries than to the bountiful seasons at home. Twice in the decade the import of butter from colonial sources fell off slightly from the previous year, namely, in 1896 and 1898, while only once was there any decrease in the foreign supply, and this occurred in 1900. In 1896 the colonial supply fell off by 5000 tons, principally owing to drought in Australia, but from foreign countries this deficiency was more than made good, as the increased import from these sources exceeded 16,500 tons. In 1900 the position was reversed, for while the foreign import fell away to the extent of over 8000 tons, the supply from the colonies exceeded that of 1899 by 15,000 tons, thus leaving a gain in the quantity of imported butter of nearly 7000 tons on the year. Table XII. shows that over the ten years 1891 to 1900 the import of colonial butter was augmented by 34,600 tons, and that of foreign by 33,600 tons, so that the increased import is fairly divided between colonial and foreign sources. If, however, the last five years of the period be taken, it will be seen that the increases in the arrivals of colonial butter have far exceeded those from foreign countries. Between 1891 and 1900 the Australasian colonies increased their quota by 13,400 tons, and Canada by 11,100 tons. Of foreign countries, Denmark showed the greatest development in the supply of imported butter, which increased in the ten years by 28,678 tons. Next came Russia and Holland, with increases respectively of 7207 tons and 6589 tons. Sweden, which made steady progress from 1891 to 1896, subsequently declined, and in 1900 sent 1400 tons less than in 1891. France and Germany are rapidly falling away, and the latter country will soon cease its supply altogether. Up to 1896 it was 6000 tons annually; by 1900 it had fallen to 1850 tons. France, which in 1892 sent to the United Kingdom 29,000 tons, regularly declined, and in 1900 sent only 16,800. Among the countries sending the smaller quantities, Argentina, Belgium, and Norway are all gradually increasing their supplies; but their totals are comparatively insignificant, as they together contributed in 1900 only 6400 tons out of a total foreign supply of 134,000 tons. The United States was erratic in its supplies during the decade, and up to 1900 had not made butter specially for export to the United Kingdom, as all the other foreign countries had done. Consequently it is only when supplies from elsewhere fail that American butter is sought for by British buyers. The large amount of salt in this butter, although suitable for the American palate, prevents its becoming popular in the United Kingdom.

The sources whence the United Kingdom receives butter from abroad are sufficiently indicated in Table XIII., which shows the absolute quantities and the relative proportions sent by the chief contributory countries in each of the four years 1897 to 1900, the order of precedence of the several countries being in accord with the figures for 1900. Denmark, as a result of the efforts made by that little kingdom to supply a sound product of uniform quality, possesses over 40 per cent. of the trade, and in the year 1900 received from the United Kingdom upwards of eight million pounds sterling for butter and over three million pounds sterling for bacon, the raising of pigs for the consumption of separated milk being an important adjunct of the dairying industry in Denmark, where butter factories are extensively maintained on the co-operative principle. It is worthy of note that some at least of the butter received in the United Kingdom from Russia is made in Siberia, whence it is sent at the outset on a long land journey in refrigerated railway cars for shipment at a Baltic port, usually Riga. The countries not specifically enumerated in Table XIII. from which butter is sent to the United Kingdom

are Argentina, Belgium, Norway, and Spain—these are included in "other countries."

In Table XIV., relating to the estimated home production of cheese and the imports of that article, the ten years' average indicates a home-made supply of 55·3 per cent., imports of colonial cheese 24·2 per cent., and imports of foreign cheese 20·5 per cent. Comparing, however, the first with the last year of the period 1891 to 1900, it appears that in 1891 the proportions were 58·6 per cent. home-made, 17·2 per cent. colonial, and 24·2 per cent. foreign, whereas in 1900 the percentages were 50·3, 28·9, and 20·8 respectively. Hence the colonial contribution (chiefly Canadian) has gained ground at the expense both of the home-made and of the foreign. Again, comparing 1891 with 1900, the import of cheese into the United Kingdom increased to the extent of only 24,500 tons, so that it shows no expansion comparable with that of butter, which increased by about 70,000 tons. Simultaneously the estimated home production diminished by 17,000 tons.

In imported colonial cheese Canada virtually has the field to itself, for the only other colonial cheese which

finds its way into the United Kingdom is from New Zealand, but the amount of this kind is comparatively insignificant, having been in 1900 only 4000 tons out of a total import of 128,600 tons. Australia, in several seasons since 1891, sent small quantities, but they are not worth quoting.

From foreign countries the decline in the export of cheese is mainly in the case of the United States, which shipped to British ports 10,000 tons less in 1900 than in 1891. France also is losing its cheese trade in British markets, and is being supplanted by Belgium. In 1891 France supplied over 3000 tons, in 1900 the import was below 2000 tons. Belgium in 1891 supplied less than 1000 tons, but in 1900 contributed 2600 tons. The import trade in Dutch cheese remains almost stationary. In 1891 it amounted to 15,300 tons, in 1899 it was 15,600 tons, whilst in 1900, owing to exceptionally high prices, which stimulated the manufacture, it reached 17,000 tons.

Over 80 per cent. of the cheese imported into the United Kingdom is derived from North America, but the bulk of the trade belongs to Canada, which supplies nearly 60 per cent. of the entire import. The value of the

cheese exported from Canada to the United Kingdom in the calendar year 1900 was close upon £3,800,000. As is shown in Table XV. above, Holland, Australasia, and France participate in this trade, whilst amongst the "other countries" are Germany, Italy, and Russia. The cheese sent from North America and Australasia is mostly of the substantial Cheddar type, whereas soft or "fancy" cheese is the dominant feature of the French shipments. Thus, in the calendar year 1900 the average price of the cheese imported into the United Kingdom from France was 61s. per cwt., whilst the average value of the cheese from all other sources was 50s. per cwt., there being a difference of 11s. in favour of the "soft" cheese of France.

The imports of butter and margarine into the United Kingdom were not separately distinguished before the year 1886. Previous to that date they amounted, at five year intervals, to the following aggregate quantities:—

| | 1870. | 1875. | 1880. | 1885. |
|---|---|---|---|---|
| Cwt. . . | 1,159,210 | 1,467,870 | 2,326,305 | 2,401,373 |

For the same years the imports of cheese registered the subjoined totals:—

| | 1870. | 1875. | 1880. | 1885. |
|---|---|---|---|---|
| Cwt. . . | 1,041,281 | 1,627,748 | 1,775,997 | 1,833,832 |

The imports of butter and margarine, both separately and together, and also the imports of cheese in each year from 1886 to 1900 inclusive, are set out in Table XVI., the most significant feature of which is the rapid expansion it shows in the imports of butter. In the space of nine

years, between 1887 and 1896, the quantity was doubled. On the other hand, the general tendency of the imports of margarine, which have been much more uniform than those of butter, has been in the direction of decline since 1892. It is necessary, however, to point out that there has been an increase in the number of margarine factories in the United Kingdom, and in the quantity of margarine manufactured in them, during the last few years. Taking the imports of butter and margarine together, the aggregate in 1899 and also in 1900 was practically three times as large as a quarter of a century earlier, in 1875. The imports of cheese have increased at a less rapid rate than those of butter, and the quantity imported in 1900, which was a maximum, fell considerably short of twice the quantity in 1875. In 1886, 1887, 1888, 1890, and 1892 the imports of cheese exceeded those of butter, but since the last-named year those of butter have always been the larger, and in 1899 were fully a million cwt. more than the cheese imports. The cheapness of imported fresh meat has probably had the effect of checking the growth of the demand for cheese amongst the industrial classes.

The imports of condensed milk into the United Kingdom

were not separately distinguished before 1888. In that year they amounted to 352,332 cwt. The quantities imported in subsequent years were the following:—

| Year. | Cwt. | Year. | Cwt. | Year. | Cwt. |
|---|---|---|---|---|---|
| 1889 | 339,892 | 1893 | 501,005 | 1897 | 756,243 |
| 1890 | 407,426 | 1894 | 529,465 | 1898 | 817,274 |
| 1891 | 444,666 | 1895 | 545,394 | 1899 | 824,599 |
| 1892 | 481,374 | 1896 | 611,335 | 1900 | 986,741 |

The quantity thus increased continuously in each year after 1889, with the result that in 1900 the imports had grown to nearly three times the amount of those in 1889. Simultaneously, over the period 1889–1900 the annual value of the imports steadily advanced from £704,849 to £1,405,033. Thus, while the imports of condensed milk trebled in quantity, they doubled in value. A fair proportion is, however, exported, as is shown in the following statement of exports of imported condensed milk for the four years 1897 to 1900:—

| | 1897. | 1898. | 1899. | 1900. |
|---|---|---|---|---|
| Quantity, cwt. | 143,932 | 133,596 | 118,394 | 164,602 |
| Value | £274,578 | £256,525 | £228,446 | £309,460 |

There is also an export trade in condensed milk made in the United Kingdom. Thus, in 1892 the exports of home-made condensed milk amounted to 61,442 cwt., valued at £133,556. By 1896 the quantity had almost doubled, and reached 111,959 cwt., of the value of £224,831. In subsequent years the exports were:—

| | 1897. | 1898. | 1899. | 1900. |
|---|---|---|---|---|
| Quantity, cwt. | 154,901 | 178,055 | 185,749 | 209,447 |
| Value | £302,748 | £343,070 | £353,819 | £390,559 |

Milk and cream (fresh or preserved other than condensed) received no separate classification in the imports until 1894, in which year the quantity imported was 161,633 gallons, followed by 126,995 gallons in 1895, and 22,776 gallons in 1896. The quantities have since been returned by weight—10,006 cwt. in 1897, 10,691 cwt. in 1898, 7859 cwt. in 1899, and 15,638 cwt. in 1900. The values of these imports in the successive years 1894 to 1900 were £21,371, £19,991, £5489, £9848, £11,293, £16,068, and £26,837.

The total values of the imports of dairy produce of all kinds—butter, margarine, cheese, &c.—into the United Kingdom were, at five-year intervals between 1875 and 1890, the following:—

| | 1875. | 1880. | 1885. | 1890. |
|---|---|---|---|---|
| Value | £13,211,592 | £17,232,548 | £15,632,852 | £19,505,798 |

The values in each year of the closing decade of the 19th century are set forth in Table XVII., where the totals in the last column include small sums for margarine-cheese and, since 1893, for fresh milk and cream. The aggregate value more than doubled during the last quarter of the century. The earliest year for which the value of imported butter is separately available is 1886, when it amounted to £8,141,438. Thirteen years later this sum had more than doubled, and it is an impressive fact that in the closing year of the century the United Kingdom should have expended on imported butter alone a sum closely approximating to 17½ million pounds sterling, equivalent to about three-fourths of the total amount disbursed on imported wheat grain.[1]

TABLE XVII. *Values of Dairy Products imported into the United Kingdom from* 1891 *to* 1900, *in Thousands of Pounds Sterling.*

| Year. | Butter. | Margarine. | Cheese. | Condensed Milk. | Total. |
|---|---|---|---|---|---|
| | £1000. | £1000. | £1000. | £1000. | £1000. |
| 1891 | 11,591 | 3558 | 4813 | 900 | 20,863 |
| 1892 | 11,965 | 3713 | 5417 | 930 | 22,025 |
| 1893 | 12,754 | 3655 | 5161 | 1010 | 22,580 |
| 1894 | 13,457 | 3045 | 5475 | 1079 | 23,077 |
| 1895 | 14,245 | 2557 | 4675 | 1084 | 22,581 |
| 1896 | 15,344 | 2498 | 4900 | 1170 | 23,920 |
| 1897 | 15,917 | 2485 | 5886 | 1398 | 25,715 |
| 1898 | 15,962 | 2384 | 4970 | 1436 | 24,779 |
| 1899 | 17,214 | 2549 | 5503 | 1455 | 26,747 |
| 1900 | 17,450 | 2465 | 6838 | 1743 | 28,544 |

The imports of margarine—that is, of margarine specifically declared to be such—into the United Kingdom are derived almost entirely from Holland. Out of a total of 920,416 cwt. imported in 1900 Holland supplied 862,154 cwt., and out of £2,464,839 expended on imported margarine in the same year Holland received £2,295,174. To the imports in the year named Holland contributed 93·7 per cent.; France, 2·9; Norway, 0·9; all other countries, 2·5; so that Holland possesses almost a monopoly of this trade. The quantities of imported butter, margarine, and cheese that are again exported from the United Kingdom are trivial when compared with the imports, as will be seen from the following quantities and values in the three years 1898 to 1900:—

| | 1898. | 1899. | 1900. | 1898. | 1899. | 1900. |
|---|---|---|---|---|---|---|
| | Cwt. | Cwt. | Cwt. | £ | £ | £ |
| Butter | 63,491 | 50,453 | 51,583 | 319,806 | 257,999 | 258,931 |
| Margarine | 10,023 | 13,139 | 11,326 | 24,721 | 33,319 | 27,882 |
| Cheese | 56,694 | 56,390 | 55,982 | 159,210 | 163,991 | 168,369 |

There is also a very small export trade in butter and cheese made in the United Kingdom, but its insignificant character is evident from the subjoined details as to quantities and values for the years named:—

| | 1898. | 1899. | 1900. | 1898. | 1899. | 1900. |
|---|---|---|---|---|---|---|
| | Cwt. | Cwt. | Cwt. | £ | £ | £ |
| Butter | 11,359 | 9936 | 10,127 | 59,731 | 53,195 | 53,701 |
| Cheese | 10,126 | 9758 | 9,356 | 36,803 | 35,890 | 36,691 |

## AMERICAN DAIRYING.

The development of the dairying industry in the vast region of the United States of America has been described in the official *Year-Book* by Major Henry E. Alvord, chief of the dairy division of the Bureau of Animal Industry in the Department of Agriculture at Washington. The beginning of the 20th century found the industry upon an altogether higher level than seemed possible a few decades earlier. The milch cow herself, upon which the whole business rests, has become almost as much a machine as a natural product, and a very different creature from the average animal of bygone days. The few homely and inconvenient implements for use in the laborious duties of the dairy have been replaced by perfected appliances, skilfully devised to accomplished their object and to lighten labour. Long rows of shining metal pans no longer adorn rural dooryards. The factory system of co-operative or concentrated manufacture has so far taken the place of home dairying that in entire states the cheese vat or press is as rare as the handloom, and in many counties it

[1] In 1901 the United Kingdom imported 3,702,810 cwt. of butter, valued at £19,297,005, both totals being the largest on record.

is as difficult to find a farm churn as a spinning-wheel. An illustration of the nature of the changes is afforded in the butter-making district of Northern Vermont, at St Albans, the business centre of Franklin county. In 1880 the first creamery was built in this county; ten years later there were 15. Now a creamery company at St Albans has upwards of 50 skimming or separating stations distributed through Franklin and adjoining counties. To these is carried the milk from more than 30,000 cows. Farmers who possess separators at home may deliver cream which, after being inspected and tested, is accepted and credited at its actual butter value, just as other raw material is sold to mills and factories. The separated cream is conveyed by rail and waggon to the central factory, where in one room from 10 to 12 tons of butter are made every working day—a single churning place for a whole county! The butter is all of standard quality, "extra creamery," and is sold on its reputation upon orders received in advance of its manufacture. The price is relatively higher than the average for the product of the same farms fifty years earlier. This is mainly due to better average quality and greater uniformity—two important advantages of the creamery system.

In one important detail dairy labour is the same as a century ago. Cows still have to be milked by hand. Although many attempts have been made, and patent after patent has been issued, no mechanical contrivance has yet proved a practical success as a substitute for the human hand in milking. Consequently, twice (or thrice) daily every day in the year, the dairy cows must be milked by manual labour. This is one of the main items of labour in dairying, and is a delicate and important duty. Assuming 10 cows per hour to a milker, which implies quick work, it requires the continuous service of an army of 300,000 men, working 10 or 12 hours a day throughout the year, to milk the cows kept in the United States.

The business of producing milk for urban consumption, with the accompanying agencies for transportation and distribution, has grown to immense proportions. In many places the milk trade is regulated and supervised by excellent municipal ordinances, which have done much to prevent adulteration and to improve the average quality of the supply. Quite as much is, however, being done by private enterprise through large milk companies, well organized and equipped, and establishments which make a speciality of serving milk and cream of fixed quality and exceptional purity. Such efforts to furnish "certified" and "guaranteed" milk, together with general competition for the best class of trade, are doing more to raise the standard of quality and improve the service than all the legal measures. The buildings and equipment of some of these modern dairies are beyond precedent. This branch of dairying is advancing fast, upon the safe basis of care, cleanliness, and better sanitary conditions.

Cheese-making has been transferred bodily from the domain of domestic arts to that of manufactures. In the middle of the 19th century about 100,000,000 ℔ of cheese was made yearly in the United States, and all of it in farm dairies. At the beginning of the 20th century the annual production is about 300,000,000 ℔, and 96 or 97 per cent. of this is made in factories. Of these there are nearly 3000, but they vary greatly in capacity, and some are very small. New York and Wisconsin possess a thousand each, but the former state makes nearly twice as much cheese as the latter, whilst the two together produce three-fourths of the entire output of the country. A change is taking place in the direction of bringing a number of factories previously independent into a "combination" or under the same management. This tends to improve the quality and secure greater uniformity in the product, and often reduces cost of manufacture. More than nine-tenths of all the cheese made is of the familiar standard type, copied after the English Cheddar, but new kinds and imitations of foreign varieties are increasing. The annual export of cheese from the United States ranges between 30,000,000 and 50,000,000 ℔. The consumption *per capita* does not exceed 3½ ℔ per annum, which is much less than in most European countries.

Butter differs from cheese in that it is still made much more largely on farms in the United States than in creameries. Creamery butter controls all the large markets, but this represents little more than one-third of the entire business. Estimating the annual butter product of the entire country at 1,400,000,000 ℔, not much over 500,000,000 ℔ of this is made at the 7500 or 8000 creameries in operation. Iowa is the greatest butter-producing state, and the one in which the greater proportion is made on the factory plan. The total output of butter in this state is one-tenth of all made in the Union. The average quality of butter has materially improved since the introduction of the creamery system and the use of modern appliances. Nevertheless, a vast quantity of poor butter is made—enough to afford a large and profitable business in collecting it at country stores at grease prices or a little more, and then rendering or renovating it by patent processes. This renovated butter has been fraudulently sold to a considerable extent as the true creamery article, of which it is a fair imitation while fresh, and several states have made laws for the identification of the product and to prevent buyers from being imposed upon. No butter is imported, and the quantity exported is insignificant, although there is beginning to be a foreign demand for American butter. The home consumption is estimated at the yearly rate of 20 ℔ per person, which, if correct, would indicate Americans to be the greatest butter-eating people in the world. The people of the United States also consume millions of pounds every year of butter substitutes and imitations, such as oleomargarine and butterine. Most of this is believed to be butter by those who use it, and the State Dairy Commissioners are busily employed in carrying out the laws intended to protect purchasers from these butter frauds.

The by-products of dairying have, within recent years, been put to economical uses, in an increasing degree. For every pound of butter made there are 15 to 20 ℔ of skim-milk and about 3 ℔ of butter-milk, and for every pound of cheese nearly 9 ℔ of whey. Up to 1889 or 1890 enormous quantities of skim-milk and butter-milk from the creameries and of whey from the cheese factories were entirely wasted. At farm dairies these by-products are generally used to advantage in feeding animals, but at the factories —especially at the seasons of greatest milk supply—this most desirable method of utilization is to a great extent impracticable. In many places new branches have been instituted for the making of sugar-of-milk and other commercial products from whey, and for the utilization of skim-milk in various ways. The albumin of the latter is extracted for use with food products and in the arts. The casein is desiccated and prepared as a substitute for eggs in baking, as the basis of an enamel paint, and as a substitute for glue in paper-sizing. It has also been proposed to solidify it to make buttons, combs, brush-backs, electrical insulators, and similar articles.

No census of cows in the United States was taken until the year 1840, but they have been enumerated in each subsequent decennial census. From 23 to 27 cows to every 100 of the population were required to keep the country supplied with milk, butter, and cheese, and provide for the export of dairy products. The export trade, though it has fluctuated considerably, has never exceeded the produce of 500,000 cows. At the close of the 19th century it was estimated that there was one milch cow in the United States for every four persons, making the number of cows about 17,500,000. They are, however, very unevenly distributed, being largely concentrated in the great dairy states, Iowa leading with 1,500,000 cows, and being followed closely by New York. In the middle and eastern states the milk product goes very largely to the supply of the numerous large towns and cities. In the central, west, and north-west butter is the leading dairy product.

Table XVIII. shows approximately the quantity and value of the dairy products of the United States in 1899, the grand total representing a value of $451,600,000. Adding to this the skim-milk, butter-milk, and whey, at their proper feeding value, and the calves dropped yearly, the annual aggregate value of the produce of the dairy cows exceeds $500,000,000, or is more than one hundred million pounds sterling. Accepting these estimates as conservative, they show that the commercial importance of the dairy industry of the United States is such as to justify all reasonable provisions for guarding its interests.

TABLE XVIII. *Estimated Number of Cows and Quantity and Value of Dairy Products in the United States in* 1899.

| Cows. | Product. | Rate of Product per Cow. | Total Product. | Rate of Value. | Total Value. |
|---|---|---|---|---|---|
| | | | | Cents. | Dollars. |
| 11,000,000 | Butter | 130 ℔ | 1,430,000,000 ℔ | 18 | 257,400,000 |
| 1,000,000 | Cheese | 300 ℔ | 300,000,000 ℔ | 9 | 27,000,000 |
| 5,500,000 | Milk | 380 gals. | 2,090,000,000 gals. | 8 | 167,200,000 |

(W. FR)

**Dalaguete,** a town on the east coast of the island of Cebú, Philippine Islands, in 9° 52′ N. It has a hot but healthful climate. The growing of Indian corn, sibucao, cacao, copra, and sugar, and the weaving of rough fabrics, are the sole occupations of its inhabitants. The language is Cebú-Visayan. Population, 21,000.

**Dalbeattie,** a police burgh of south-east Kirkcudbrightshire, Scotland, 14½ miles south-west of Dumfries by rail. There are important quarries in the neighbourhood, and steam granite-polishing works in the town. There is a prospect of ironstone being worked. There is a town-hall, a mechanics' institute, and a church hall. Population (1891), 3149; (1901), 3462.

**Dale, Robert William** (1829–1895), Congregationalist divine, was born in London, 1st December 1829, and was educated for the Congregational ministry. In 1853 he became co-pastor of Carr's Lane Chapel, Birmingham, with the veteran John Angell James. At first the liberality of his theology occasioned much suspicion and offence, over which, partly owing to the support of the senior minister, he so completely triumphed as to become sole pastor on the latter's death in 1859. He was for many years one of the most influential personalities in Birmingham, and took the most active part in the remarkable municipal development of that city. He was especially conspicuous in the controversies arising out of the Education Act of 1870, which, so far as Birmingham was concerned, were terminated in 1879 by a compromise, of which Dale disapproved. His adherence to Mr Chamberlain on the Irish Home Rule question did not diminish his influence. His sympathies were broad, and he had many warm friends in the Church of England. He died on 13th March 1895.

**Dalecarlia,** in Swedish *Dalarne* ("the Dales"), in popular usage the name of a very characteristic region in the middle of Sweden, characteristic in respect of its productions, but even more so in respect of its people. It is virtually the same as the county of Kopparberg, of which Falun is the chief town. The Dalecarlians or Dalesmen speak their own peculiar dialect (see a paper by A. Noreen in *De Svenska Landsmålen*, vol. iv., 1881), wear their own peculiar costumes, and are famed for their brave spirit and sturdy love of independence. More than once they have played a decisive *rôle* in the history of Sweden. In 1434, led by Engelbrecht, the miner, they rose against the oppressive tyranny of the officers of Erik XIV. of Denmark, and in 1519-23 it was amongst them that Gustavus Vasa found his staunchest supporters in his patriotic task of freeing Sweden from the yoke of the Danes. The districts around Lakes Runn and Siljan ("the Eye of the Dales"), the principal sheets of water in the valleys of the Dal rivers, are consequently classic ground. The people are for the most part small peasant proprietors. In 1894, out of 27,848 estates, no less than 27,287 were under 50 acres in extent. They eke out their scanty returns from tilling the soil by a variety of home industries, such as making scythes, saws, bells, wooden wares, hair goods, and so forth. The larger portion of the area is, however, covered with forest (75·4 per cent. in 1897), only 7·1 per cent. being under cultivation. Besides the wealth of the forests, the Dales contain some of the largest and most prolific iron mines in Sweden, especially Grängesberg. In 1898 the iron mines of Dalecarlia yielded 751,038 tons of iron ore, or 32·6 per cent. of the entire output of the kingdom. Nor is iron the only mineral. In Dalecarlia, too, are the far-famed copper mines of Falun, as well as mines of silver and lead, zinc and sulphur. In consequence of this the district has numerous smelting furnaces, blasting and rolling mills, iron and metallurgical works, as well as sawmills, wood-pulp factories, chemical works, and so forth.

See G. H. MELLIN, *Skildringar af den Skandinaviska Nordens Folklif og Natur*, vol. iii. (1865), and FREDERIKA BREMER, *I Dalarne* (1845), of which there is an English translation by Wm. and Mary Howitt (1852).

**Dalias,** a town of Spain in the province of Almeria, 8 miles from the Mediterranean. Population in 1897, 6341. In its neighbourhood are the ruins of an older town, walls, tombs, aqueducts. Between Dalias and the sea are small lagoons and an old castle turned into a guardhouse for the carabiniers. The streets are narrow and irregular, and there is no public building worth mentioning, except a parish church and the town-hall, both comparatively modern. An earthquake on 25th August 1804 destroyed most of the houses and churches, and 162 inhabitants were killed. The trade of Dalias consists of wheat, wine, oil, oranges, esparto-grass, and fruit.

**Dalkeith,** a police burgh and market-town in the county of Edinburgh, situated between the North and South Esk, 6¾ miles south-east from Edinburgh P.O. and about 5 miles from the city boundary. In 1899 the parish contained 7704 inhabitants (W. parish, 4323; E. parish, 3381), and in 1901 the police burgh had 6753. The rental of lands in the parish for 1899-1900 amounted to £40,156. In recent years Eskbank (within the parish and burgh) has been made a handsome residential quarter. The only changes of note in the industries of the town are the closing of the iron-foundry and the opening of a colliery near Eskbank. A pipe supply of water has been introduced from the Edinburgh district works, and has been supplemented by a local water scheme.

**Dallas,** capital of Dallas county, Texas, U.S.A., in 32° 45′ N. lat. and 96° 46′ W. long., on the eastern bank of Trinity river, which here is not navigable. It is at an altitude of 422 feet. It has a level site, a fairly regular plan, is sewered, and has a good water supply. It is the third city in population and the most important railway centre in Texas, being entered by five railways, four of which are trunk lines. It is in a rich agricultural region, which produces cotton, wheat, and Indian corn, and it has large trade and extensive manufactures. In 1890 its manufacturing capital was $5,250,000, employing 4082 hands, and the products were worth over $9,000,000. Prominent among these were flour and leather goods. In 1900 the assessed valuation of real and personal property, on a basis of about one-half of the full value, was $23,016,600, the net debt $1,759,458, and the tax rate from $24.02 to $24.50 per $1000. Dallas was founded in 1841, but most of its growth has come in recent years. Population (1880), 10,358; (1890), 38,067; (1900), 42,638, of whom 9035 were negroes.

**Dalmatia** (German, *Dalmatien*; Serbo-Croatian, *Dalmacija*), a crownland and kingdom of the Cisleithan part of the Austro-Hungarian monarchy. It is separated from the rest of Austria by Croatia, which belongs to the Hungarian half of the monarchy. Ethnographically and geographically it is part of the lands of the Hungarian crown, and is still included in the official title of the Kingdom of Croatia. Its reincorporation is one of the objects aimed at by a considerable section of the Croatian people. Population in 1869, 456,961; in 1880, 476,101; in 1890, including garrison of 5400 men, 527,426, the equivalent of 106·83 inhabitants per square mile; in 1900, 591,597. Proportion of females to males (1890), 993 to 1000. The Serbo-Croatians constitute 96·2 per cent. and the Italians 3 per cent. of the population, the former increasing, the latter declining. The remainder is made up of

Germans, Czechs, Slovenes, &c. 83·3 per cent. are of the Roman Catholic and 16·5 per cent. of the Greek Orthodox faith. There are 329 Jews. In 1896 the marriage-rate was 7·34, the birth-rate 40·01, or excluding still-births, 39·65, and the death-rate 29 per thousand. Of the births, 3·84 per cent. were illegitimate, with the exception of Görz and Gradisca the lowest proportion in Austria. Dalmatia sends 11 members to the Reichsrath. In the provincial Diet there are 28 Croatians, 9 Servians, and 6 Italians. The distinction drawn between Croatians and Servians in Dalmatia, as also in Croatia and Slavonia, is political and religious, and not one of race. The Croatians and Servians of those parts speak the same language, but the former are Roman Catholic and use the Latin characters in writing, and the latter are Orthodox and employ the Cyrillic characters. Notwithstanding the progress during the period 1860–1900, Dalmatia remained the most backward of the Austrian crownlands in the matter of education. In 1890, 82·8 per cent. of the population were returned as illiterate, that proportion being an improvement of 4 per cent. on the census of 1880. It possessed, in 1893, 5 intermediate and 337 elementary schools, attended by 88·4 per cent. of the children, 6 theological seminaries, 6 gymnasia, and some 40 technical and continuation schools. Of the 28 periodicals, 21 are in the Serbo-Croatian language, 5 in Italian, 1 in Latin, and 1 in polyglot. But a small proportion of the population (4·58 per cent.) is engaged in industry and mining, and 4·8 per cent. in trade and transport. Viticulture, which has latterly made great progress, cattle-breeding, and the cultivation of the olive tree, vegetables, and fruit are among the principal resources, a large number of the inhabitants also finding employment as sailors and in sea-fishing. A small quantity of sea salt is recovered by evaporation. Other industries are ship-building (which is of considerable importance), the manufacture of liqueurs (Maraschino), spirits, soap, oil, &c. Its commerce consists mainly of a lucrative transit trade with Bosnia and Herzegovina, Montenegro, Turkey, and the ports of the Adriatic and the Mediterranean. In 1890 the Dalmatian mercantile marine numbered 8 steamers and nearly 6000 sailing vessels of all sizes. Communications are in a backward state. In 1897 there were 125 kilometres of railway, 2857 kilometres of roads, and 55 kilometres of navigable waterway. There were 151 post and 98 telegraph offices.

See T. G. Jackson, *Dalmatia, the Quarnero, and Istria* (Oxford, 1887); and works by Goracucchi, Schatzmayer, Ruthner, Cons, Nolhac, Schweiger-Lerchenfeld, Eitelberger, and Pisrni.

(Æ. O'N.)

**Dalny,** a new Russian free port, opened to foreign trade in 1901, situated on the Central Manchurian Railway, and thus one of the Pacific termini of the Trans-Siberian Railway. It stands at the head of Talien-wan Bay, on the east side of Liao-tung peninsula, in Manchuria, about 20 miles north-east from Port Arthur and twenty-one days' journey by rail from St Petersburg. The harbour is roomy, easy of entrance, and free from ice all the year round. Population (1901), 50,000, of whom about one-half were workmen, mostly Chinese.

**Dalry,** a mining and manufacturing town of Ayrshire, Scotland, on the river Garnock, 17½ miles north by west of Ayr. There is a public hall, library, and a public park (1893). Ironstone is extensively worked, and the town contains woollen factories and a large worsted spinning mill. The other industries embrace cabinet-making, coke-making, brick-making, machine-knitting, box-making, currying, and the manufacture of aërated waters. The churches are two Established, two United Free, Episcopal, and Roman Catholic, and there are two memorial mission halls. Three public schools had an average attendance of 698 in 1898–99, a female industrial school 184, and a church school 129. Population (1881), 5010; (1891), 4572; (1901), 5314.

**Dalton-in-Furness,** a market-town and railway station in the North Lonsdale parliamentary division of Lancashire, England, 4 miles north-east by north of Barrow-in-Furness. The ruins of Furness Abbey are near, and Dalton Castle stands on an eminence in the town. There are Established, Roman Catholic, and various Nonconformist churches. There are numerous iron-ore mines in the parish, and ironworks at Askam, in the northern part of the district. Area (an urban district), 7223 acres. Population (1881), 13,339; (1901), 13,020.

**Damanhur,** a town and important railway station of Lower Egypt, 10 miles from Alexandria, capital of the richly cultivated province of Behera. The town stands on the site of the ancient Egyptian *Pa-Tahoth*, the *Hermopolis Parva* of the Romans. A much frequented fair is held here three times a year, and there are several cotton manufactories. Population (1900), 19,600.

**Damão** or **Damaun,** a town of Portuguese India, capital of district Damão, is situated on the east side of the entrance of the Bay of Cambay. Area of district, 148 sq. miles. Population (1894), 64,248. Salt is produced by 500 to 600 men to the extent of nearly 3000 tons annually. The cajuri palm is cultivated.

**Damaraland.** See South-West Africa, German.

**Damascus** (Hebrew, *Dammesek*, or *Darmesek;* Egyptian, *Timasku;* Assyrian, *Dimaski;* Arabic, *Dimishk esh-Shám*, or simply *esh-Shám*), the largest town in Syria, and the capital of the esh-Shám (Syria) viláyet, situated near the northern edge of the Ghúta, a fertile plain at the foot of Anti-Lebanon, at an altitude of 2250 ft. above the sea. It is the seat of the governor-general, of the Mushir commanding the 5th Army Corps, and of British and other consuls, and is connected by rail with its port, Beirút, and with el-Mezeiríb in the Haurán. The Ghúta is irrigated by the Baradá (see Abanah) and the 'Awaj, which flow eastward in several channels, and lose themselves, about 18 miles from the city, in small marshes at the edge of the Syrian desert. The plain is covered nearly everywhere with luxuriant vegetation, out of which, where the foliage is densest and most beautiful, rise the minarets and domes of the "white smokeless city." The delicious verdure and the all-pervading presence of running water constitute an abiding charm, which is heightened by the barren hills that almost surround the great oasis. Damascus stands on both banks of the main stream of the Baradá, about two miles from the mouth of the gorge through which the river runs to the plain. Most of the city, including the oldest portion, which was enclosed by a wall, lies on the right bank, and from it a long suburb, el-Meidán, stretches southwards for more than a mile along the Haj road to Mecca. On the left bank is a large suburb, el-'Amára, of later date, and north of this, at the foot of the hills, lies the beautiful suburb es-Salihíyeh. The old wall, Arab and Turkish, on Roman or perhaps earlier foundations, was pierced by several gates, and the city was traversed from east to west by a colonnaded street, "the street which was called Straight," still named Derb el-Mustakím. In the north-west corner, near the Baradá, which filled its moat, is the castle built, A.D. 1219, by el-Melik el-Ashraf. It stands on the site of an earlier building, possibly a palace, which was connected with a temple to the east, now represented by the Great Mosque of the Omeiyads. This mosque, destroyed by fire on the 14th of October 1893, and now being rebuilt, was a reconstruction, by the Khalíf el-Walíd (705–715), of the Church of St

John, built by Arcadius (395–408), on a site previously occupied by Roman, Greek, and earlier temples. Traces of the church and of the two later temples are still visible, and recent research has shown that they, and their courts, stood near the centre of a great enclosure measuring 1300 feet from east to west and 1000 feet from north to south. The streets are still narrow, crooked, and in great part unpaved. The best is the Derb el-Mustakím, which separates the Christian and Jewish quarters. The water of the Baradá is led through every quarter; but the supply is not well regulated, and in autumn the water is often unwholesome. In the gardens which surround the city grow walnut, apricot, pomegranate, almond, &c.; and beyond them are fields of wheat, barley, and maize. The climate is good: in winter there is often hard frost and much snow, and even in summer, with a day temperature of 100° F., the nights are always cool. Fever, dysentery, and ophthalmia, chiefly due to exposure to heavy dews and cold nights, are prevalent.

In 1894–95 the Damascus-Mezeiríb and Damascus-Beirút Railways were opened, and they are now worked at a loss by a French company. Damascus appears to have been an important manufacturing, agricultural, and commercial centre from an early time. Its position in a fertile oasis on the edge of the desert, with roads leading to Northern Syria, the Euphrates and Persian Gulf, Arabia, Egypt, and Acre, its natural port, enabled it to recover after every disaster, and until the opening of the Suez Canal it retained its importance. It is still the market of the nomads, but the surer and cheaper sea route has almost destroyed the transit trade to which it owed its wealth, and has even diminished the importance of the annual pilgrim caravan (Haj) to Mecca. The Damascene, however, still retains his skill as a craftsman and tiller of the soil. The furniture of mosaic wood-work, the iron, copper, and brass work, and the woven goods in cotton, silk, and wool, show great artistic taste. The principal exports are silk and cotton fabrics, wool, apricot paste, wooden and brass goods, starch, rope, &c.; and the imports are cloths, prints, muslins, raw silk, sugar, rice, &c.

The value of exports and imports in certain specified years is shown in the following table:—

| | 1890 | 1894. | 1898. |
|---|---|---|---|
| Exports . . . | £325,660 | £400,830 | £302,050 |
| Imports . . . | 525,710 | 614,490 | 675,080 |

The estimates of population vary from 154,000 (including Christians and Jews, 55,000) to 225,000 (including Christians and Jews, 35,000). Most of the Christians belong to the Orthodox and Roman Catholic (United) Greek Churches; and there are also communities of Melchites, Jacobites, Maronites, Nestorians, Armenians, and Protestants. There are British and American Missions, and a British hospital.

(C. W. W.)

**Damghán,** a town in the province of Samnán va Damghán of Persia, situated 216 miles from Teherán, on the high-road thence to Khorasan, at an elevation of 3770 feet, and in 36° 10′ N. lat. and 54° 20′ E. long. It has a population of less than 10,000. There are post and telegraph offices, and a great export trade is done in pistachios and almonds. The Damghán almonds of the kind called "Kághazí" (papery), with very thin shells, are famous throughout the country. Damghán was an important city in the Middle Ages, but only a ruined mosque, with a number of columns and some fine wood-carvings, and two minarets remain of that period. Near the city, a few miles south and south-west, are the remains of *Hecatompylos*, extending from Frát, 16 miles south of Damghán, to near Gúsheh, 20 miles west.

**Damien** [properly VEUSTER, JOSEPH DE] (1840–1889), Belgian missionary, was born at Tremeloo, near Louvain, on 3rd January 1840. He was educated for a business career, but in his eighteenth year entered the Church, joining the Society of the Sacred Heart of Jesus and Mary (also known as the Picpus Congregation), and taking Damien as his name in religion. In October 1863, while he was still in minor orders, he went out as a missionary to the Pacific Islands, taking the place of his brother, who had been prevented by an illness. Reaching Honolulu in March 1864 he was ordained priest in Whitsuntide of that year, and took up his duties as a missionary. Having observed the ravages of leprosy among the natives, and the painful scenes attending the departure of the lepers, whom it was the practice of the Hawaian Government to deport to the island of Molokai, he conceived an earnest desire to mitigate their lot, and in 1873 volunteered to take spiritual charge of the settlement at Molokai. Here he remained for the rest of his life, with occasional visits to Honolulu, until he became stricken with leprosy in 1885. Besides attending to the spiritual needs of the lepers, he managed, by the labour of his own hands and by appeals to the Hawaian Government, to improve materially the water-supply, the dwellings, and the victualling of the settlement. For five years he worked alone; subsequently other resident priests from time to time assisted him. He succumbed to leprosy on 15th April 1889. Some ill-considered imputations upon Father Damien by a Protestant clergyman produced a memorable tract by Robert Louis Stevenson, which has made Damien's self-sacrifice famous throughout the world. (J. M'F.)

**Damietta,** a town of Lower Egypt, near the mouth of the eastern branch of the Delta, terminus of the railway from Cairo, from which it is distant 125 miles by the Tanta route. The population in 1900 was 43,000, showing an increase of 9000 since 1882. Damietta gives its name to *dimity*, a kind of striped cloth, for which the place was at one time famous. Now it is chiefly important for its rice and fisheries, with which it does a brisk trade with the interior.

**Damoh,** a town and district of British India, in the Jubbulpore division of the Central Provinces. The town is a railway station, 48 miles east of Saugor. The population in 1881 was 8665; in 1891 it was 11,753.

The DISTRICT OF DAMOH has an area of 2831 square miles. The population in 1881 was 312,957, and in 1891 was 325,613, giving an average density of 115 persons per square mile. In 1901 the population was 285,138, showing a decrease of 12 per cent., due to famine. The land revenue was Rs.3,85,000, the incidence of assessment being R.0–5–3 per acre; the cultivated area in 1897–98 was 433,283 acres, of which 1858 were irrigated; the number of police was 326; the boys at school numbered 3394, being 13·6 per cent. of the male population of school-going age; the registered death-rate in 1897 was 60·84 per thousand. A branch of the Indian Midland Railway was opened throughout from Saugor to Katni (104 miles) in January 1899. Damoh suffered severely from the famine of 1896–97. Fortunately the famine of 1900 was little felt.

**Dana, Charles Anderson** (1819–1897), American journalist, was born in Hinsdale, New Hampshire, 8th August 1819; studied at Harvard University, and became a member of the Brook Farm literary, philosophical, socialistic, and agricultural community, near West Roxbury, Massachusetts, in 1842, where he had among his associates Hawthorne, George W. Curtis, George Ripley, and Margaret Fuller, the three last named being afterwards, like himself, editors in New York. As a young

man he entered ardently into the hopes of the founders of this famous enterprise, lecturing on "Friendship," &c., and remaining at Brook Farm until its abandonment in 1844; but in his later years, in the words of the historian of the community, "he departed farthest from its aspirations." After some newspaper work in Boston, Dana joined the editorial staff of Horace Greeley's New York *Tribune*, becoming its managing editor, and actively promoting the anti-slavery cause, but he left the paper in 1862, because of a sharp disagreement with Greeley regarding the conduct of the war by President Lincoln's administration. As Dana himself said: "Greeley was for peace and I was for war." Having served as a special investigating agent of the war department at the front,—informing Secretary Stanton of the capacity and methods of various generals in the field,—Dana became assistant-secretary of war in 1863, so remaining until the close of the conflict. After a brief editorial connexion in Chicago, in 1868 he became editor and chief owner of the New York *Sun*, and remained in control until his death, giving to it a flavour and character of its own, in accordance with his personal preferences and aversions. The *Sun*, under the same editorial control, was at one time a spokesman of Tammany Hall, the local democratic organization in New York City; and at another of the Republican party and its managers in city and state. In his later years, after his abandonment of the Democratic party at the time of the nomination of William J. Bryan for the Presidency, Dana was the principal advocate, in the New York press, of an aggressively "American" or national policy. Dana was also a connoisseur in art, and edited a *Household Book of Poetry* (1857) and (with George Ripley) the *New American Cyclopædia*, 15 vols. (1857-63). His reminiscences of the war, having been published in a monthly magazine, were issued in a volume in 1898. Dana died at his home at Glen Cove, Long Island, near New York, 18th October 1897.

**Dana, James Dwight** (1813-1895), American geologist, was born in Utica, New York, 12th February 1813. He early displayed a taste for science, and entered Yale College that he might study under the elder Benjamin Silliman. Graduating in 1833, for the next two years he was teacher of mathematics to midshipmen in the navy, and sailed to the Mediterranean while engaged in his duties. From 1835 to 1837 he was assistant to Professor Silliman at Yale, and then, for five years, acted as mineralogist and geologist of a United States exploring expedition, commanded by Commodore Wilkes, in the Southern and Pacific oceans. His labours in preparing the reports of such explorations as he had shared, occupied parts of thirteen years after his return to America in 1842. In 1844 he again became a resident of New Haven, married Professor Silliman's daughter, and on the resignation of Silliman was appointed Silliman Professor of Natural History and Geology in Yale College, a position which he only resigned in 1892. He was for many years, and until his death, editor of the *American Journal of Science and Arts* (founded in 1819 by Benjamin Silliman), to which he was a constant contributor, principally of articles on geology and mineralogy. A bibliographical list of his writings shows 214 titles of books and papers, beginning in 1835 with a paper on the conditions of Vesuvius in 1834, and ending with the fourth revised edition (finished in February 1895) of his *Manual of Geology*. His reports on *Zoophytes*, on the *Geology of the Pacific*, and on *Crustacea*, summarizing his work on the Wilkes expedition, appeared in 1846, 1849, and 1852-54, in quarto volumes, with copiously illustrated atlases; but as these were issued in small numbers, his general reputation more largely rests upon his *System of Mineralogy* (1837), *Manual of Geology* (1862), and *Corals and Coral Islands* (1872), the first two having repeatedly been revised in successive editions, and widely used as text-books in American colleges. In 1887 Dana visited the Hawaiian Islands to study volcanoes. He died in New Haven, 14th April 1895.

**Danao,** a town on the east coast of the island of Cebú, Philippine Islands, in 10° 28′ N. It has a comparatively cool and healthful climate, and is the centre of a rich agricultural region producing rice, Indian corn, sugar, copra, and cacao. The language is Cebú-Visayan. Population, 16,000.

**Danbury,** capital of Fairfield county, Connecticut, U.S.A., in 41° 24′ N. lat. and 73° 26′ W. long., at an altitude of 371 feet. It is entered by the New England and the New York, New Haven, and Hartford Railways. It has for a century been known for its manufacture of hats, which is still its principal industry. Besides these, it makes boots and shoes, shirts, and other articles of clothing. Population of the town (1880), 11,666; (1890), 19,473; (1900), 19,474; population of the city (1890), 16,552; (1900), 16,537.

**Dancing** is the universal human expression, by movements of the limbs and body, of a sense of rhythm which is implanted among the primitive instincts of the animal world. The rhythmic principle of motion extends throughout the universe, governing the lapse of waves, the flow of tides, the reverberations of light and sound, and the movements of celestial bodies; and in the human organism it manifests itself in the automatic pulses and flexions of the blood and tissues. Dancing is merely the voluntary application of the rhythmic principle, when excitement has induced an abnormally rapid oxidization of brain tissue, to the physical exertion by which the overcharged brain is relieved. This is primitive dancing; and it embraces all movements of the limbs and body expressive of joy or grief, all pantomimic representations of incidents in the lives of the dancers, all performances in which movements of the body are employed to excite the passions of hatred or love, pity or revenge, or to arouse the warlike instincts, and all ceremonies in which such movements express homage or worship, or are used as religious exercises. Although music is not an essential part of dancing, it almost invariably accompanies it, even in the crudest form of a rhythm beaten out on a drum. For an account of savage dances and of such customs of savage or civilized peoples as are included in this description of dancing the reader is referred to the article on Dancing in the ninth edition of this work. The present article is confined to a discussion of Modern Dancing, by which is meant dancing employed as an entertainment either for the dancers or for spectators—this being the direction in which dancing has been developed as an art in civilized countries. In its evolution, its direct application to arouse emotion or religious feeling tends to be obscured, and, although attempts are occasionally made to revive it, finally dropped out; and it is in the sense of an art or pastime that the term dancing is used in this article.

Italy, in the 15th century, saw the renaissance of dancing, and France may be said to have been the nursery of the modern art, though comparatively few modern dances are really French in origin. The national dances of other countries were brought to France, studied systematically, and made perfect there. An English or a Bohemian dance, practised only amongst peasants, would be taken to France, polished and perfected, and would at last find its way back to its own country, no more recognizable than a piece of elegant cloth when it returns from the printer to the place from which as "grey" material it was

sent. The fact that the terminology of dancing is almost entirely French is a sufficient indication of the origin of the rules that govern it. The earliest dances that bear any relation to the modern art are probably the *danses basses* and *danses hautes* of the 16th century. The *danse basse* was the dance of the court of Charles IX. and of good society, the steps being very grave and dignified, not to say solemn, and the accompaniment a psalm tune. The *danses hautes*, or *baladines*, had a skipping step, and were practised only by clowns and country people. More lively dances, such as the *Gaillarde* and *Volta* were introduced into France from Italy by Catherine de' Medici, but even in these the interest was chiefly spectacular. Other dances of the same period were the *Branle* (afterwards corrupted to *Braule*, and known in England as the Brawle)—a kind of generic dance which was capable of an almost infinite amount of variety. Thus there were imitative dances—*Branles mimés*, such as the *Branles des Ermites, Branles des flambeaux*, and the *Branles des lavandières*. The *Branle* in its original form had steps like the *Allemande*. Perhaps the most famous and stately dance of this period was the *Pavane* (of Spanish origin), which is very fully described in Tabouret's *Orchésographie*, the earliest work in which a dance is found minutely described. The *Pavane*, which was really more a procession than a dance, must have been a very gorgeous and noble sight, and it was perfectly suited to the dress of the period, the stiff brocades of the ladies and the swords and heavily plumed hats of the gentlemen being displayed in its simple and dignified measures to great advantage. The dancers in the time of Henry III. of France usually sang, while performing the *Pavane*, a *chanson*, of which this is one of the verses:

> "Approche donc, ma belle,
> Approche—toi, mon bien;
> Ne me sois plus rebelle,
> Puisque mon cœur est tien;
> Pour mon âme apaiser,
> Donne-moi un baiser."

In the *Pavane* and *Branle*, and in nearly all the dances of the 17th and 18th centuries, the practice of kissing formed a not unimportant part, and seems to have added greatly to the popularity of the pastime. Another extremely popular dance was the *Saraband*, which, however, died out after the 17th century. It was originally a Spanish dance, but enjoyed an enormous success for a time in France. Every dance at that time had its own tune or tunes, which were called by its own name, and of the *Saraband* the Chevalier de Grammont wrote that "it either charmed or annoyed everyone, for all the guitarists of the court began to learn it, and God only knows the universal twanging that followed." Vauquelin des Yveteaux in his eightieth year desired to die to the tune of the *Saraband*, "so that his soul might pass away sweetly." After the *Pavane* came the *Courante*, a court dance performed on tiptoe with slightly jumping steps and many bows and curtseys. The *Courante* is one of the most important of the strictly modern dances. The Minuet and the Waltz were both in some degree derived from it, and it had much in common with the famous *Seguidilla* of Spain. It was a favourite dance of Louis XIV., who was an adept in the art, and it was regarded in his time as of such importance that a nobleman's education could hardly have been said to be begun until he had mastered the *Courante*.

The dance which the French brought to the greatest perfection—which many, indeed, regard as the fine flower of the art—was the *Minuet*. Its origin, as a rustic dance, is not less antique than that of the other dances from which the modern art has been evolved. It was originally a *branle* of Poitou, derived from the *Courante*. It came to Paris in 1650, and was first set to music by Lully. It was at first a gay and lively dance, but on being brought to court it soon lost its sportive character and became grave and dignified. It is mentioned by Beauchamps, the father of dancing-masters, who flourished in Louis XIV.'s reign, and also by Blondy, his pupil; but it was Pécour who really gave the Minuet its popularity, and although it was improved and made perfect by Dauberval, Gardel, Marcel, and Gaétan Vestris, it was in Louis XV.'s reign that it saw its golden age. It was then a dance for two in moderate triple time, and was generally followed by the Gavotte. Afterwards the Minuet was considerably developed, and with the Gavotte became chiefly a stage dance and a means of display; but it should be remembered that the minuets which are now danced on the stage are generally highly elaborated with a view to their spectacular effect, and have imported into them steps and figures which do not belong to the Minuet at all, but are borrowed from all kinds of other dances. The original Court Minuet was a grave and simple dance, although it did not retain its simplicity for long. But when it became elaborated it was glorified and moulded into a perfect expression of an age in which deportment was most sedulously cultivated and most brilliantly polished. The "languishing eye and smiling mouth" had their due effect in the minuet; it was a school for chivalry, courtesy, and ceremony; the hundred slow graceful movements and courtesies, the pauses which had to be filled by neatly turned compliments, the beauty and bravery of attire—all were eloquent of graces and outward refinements which we cannot boast now. The fact that the measure of the Minuet has become incorporated in the structure of the Symphony shows how important was its place in the polite world. The *Gavotte*, which was often danced as a pendant to the Minuet, was also originally a peasant's dance, a *danse des Gavots*, and consisted chiefly of kissing and capering. It also became stiff and artificial, and in the later and more prudish half of the 18th century the ladies received bouquets instead of kisses in dancing the Gavotte. It rapidly became a stage dance, and it has never been restored to the ballroom. Grétry attempted to revive it, but his arrangement never became popular. Other dances which were naturalized in France were the *Ecossaise*, popular in 1760; the *Cotillon*, fashionable under Charles X., derived from the peasant *branles* and danced by ladies in short skirts; the *Galop*, imported from Germany; the *Lancers*, invented by Laborde in 1836; the *Polka*, brought by a dancing-master from Prague in 1840; the *Schottisch*, also Bohemian, first introduced in 1844; the *Bourée*, or French clog-dance; the *Quadrille*, known in the 18th century as the *Contredanse*; and the *Waltz*, which was danced as a *volte* by Henry III. of France, but only became popular in the beginning of the 19th century. We shall return to the history of some of these later dances in discussing the dances at present in use.

If France has been the nursery and school of the art of dancing, Spain is its true home. There it is part of the national life, the inevitable expression of the gay, contented, irresponsible, sunburnt nature of the people. The form of Spanish dances has hardly changed; some of them are of great antiquity, and may be traced back with hardly a break to the performances in ancient Rome of the famous dancing-girls of Cadiz. The connexion is lost during the period of the Arab invasion, but the art was not neglected, and Jovellanos suggests that it took refuge in the Asturias. At any rate, dances of the 10th and 12th centuries have been preserved uncorrupted. The earliest dances known were the *Turdion*, the *Gibidana*,

the *Pié-de-gibao*, and (later) the *Madama Orleans*, the *Alemana*, and the *Pavana*. Under Philip IV. theatrical dancing was in high popularity, and ballets were organized with extraordinary magnificence of decoration and costume. They supplanted the national dances, and the *Zarabanda* and *Chacona* were practically extinct in the 18th century. It is at this period that the famous modern Spanish dances the *Bolero*, *Seguidilla*, and the *Fandango* first appear. Of these the *Fandango* is the most important. It is danced by two people in 6–8 time, beginning slowly and tenderly, the rhythm marked by the click of castanets, the snapping of the fingers, and the stamping of feet, and the speed gradually increasing until a whirl of exaltation is reached. A feature of the *Fandango* and also of the *Seguidilla* is a sudden pause of the music towards the end of each measure, upon which the dancers stand rigid in the attitudes in which the stopping of the music found them, and only move again when the music is resumed. M. Vuillier, in his *History of Dancing*, gives the following description of the *Fandango*:—"Like an electric shock, the notes of the Fandango animate all hearts. Men and women, young and old, acknowledge the power of this air over the ears and soul of every Spaniard. The young men spring to their places, rattling castanets, or imitating their sound by snapping their fingers. The girls are remarkable for the willowy languor and lightness of their movements, the voluptuousness of their attitudes—beating the exactest time with tapping heels. Partners tease and entreat and pursue each other by turns. Suddenly the music stops, and each dancer shows his skill by remaining absolutely motionless, bounding again into the full life of the Fandango as the orchestra strikes up. The sound of the guitar, the violin, the rapid tic-tac of heels (*taconeos*), the crack of fingers and castanets, the supple swaying of the dancers, fill the spectator with ecstasy. The measure whirls along in a rapid triple time. Spangles glitter; the sharp clank of ivory and ebony castanets beats out the cadence of strange, throbbing, deepening notes—assonances unknown to music, but curiously characteristic, effective, and intoxicating. Amidst the rustle of silks, smiles gleam over white teeth, dark eyes sparkle and droop, and flash up again in flame. All is flutter and glitter, grace and animation—quivering, sonorous, passionate, seductive."

The *Bolero* is a comparatively modern dance, having been invented by Sebastian Cerezo, a celebrated dancer of the time of King Charles III. It is remarkable for the free use made in it of the arms, and is said to be derived from the ancient *Zarabanda*, a violent and licentious dance, which has entirely disappeared, and with which the later Saraband has practically nothing in common. The step of the *Bolero* is low and gliding, but well marked. It is danced by one or more couples. The *Seguidilla* is hardly less ancient than the *Fandango*, which it resembles. Every province in Spain has its own *Seguidilla*, and the dance is accompanied by *coplas*, or verses, which are sung either to traditional melodies or to the tunes of local composers; indeed, the national music of Spain consists largely of these coplas. Baron Davillier, among several specimens of *Seguidillas*, gives this one

"Mi corazon volando
Se fué á tu pecho;
Le cortaste las alas,
Y quédo dentro.
Por atrevido
Se quedará por siempre
En el metido."[1]

[1] "My heart flew to thy breast. Thou didst cut its wings, so that it remained there. And now it has waxed daring, and will stay with thee for evermore."

M. Vuillier quotes a *copla* which he heard at Polenza, in the Balearic Islands. This verse is formed on the rhythm of the *Malagueña*:

"Una estrella se ha pardida
En el ciel y no parece;
En tu cara se ha metido;
Y en tu frente resplandece."[2]

The *Jota* is the national dance of Aragon, a lively and splendid, but withal dignified and reticent, dance derived from the 16th century *Passacaille*. It is still used as a religious dance. The *Cachuca* is a light and graceful dance in triple time. It is performed by a single dancer of either sex. The head and shoulders play an important part in the movements of this dance. Other provincial dances now in existence are the *Jaleo de Jerez*, a whirling measure performed by gipsies, the *Palotéa*, the *Polo*, the *Gallegada*, the *Muyneria*, the *Habas Verdes*, the *Zapateado*, the *Zorongo*, the *Vito*, the *Tirano*, and the *Tripola Trapola*. Most of these dances are named either after the places where they are danced or after the composers who have invented tunes for them. Many of them are but slight variations from the *Fandango* and *Seguidilla*.

The history of court dancing in Great Britain is practically the same as that of France, and need not occupy much of our attention here. But there are strictly national dances still in existence which are quite peculiar to the country, and may be traced back to the dances and games of the Saxon gleemen. The Egg dance and the Carole were both Saxon dances, the Carole being a Yule-tide festivity, of which the present-day Christmas carol is a remnant. The oldest dances which remain unchanged in England are the Morris dances, which were introduced in the time of Edward III. The name Morris or Moorish refers to the origin of these dances, which are said to have been brought back by John of Gaunt from his travels in Spain. The Morris dances are associated with May-day, and are danced round a Maypole to a lively and capering step, some of the performers having bells fastened to their knees in the Moorish manner. They are dressed as characters of old English tradition, such as Robin Hood, Maid Marian, Friar Tuck, Little John, and Tom the Piper. All the true country dances of Great Britain are of an active and lively measure; they may all, indeed, be said to be founded on the jig; and the hornpipe, which is a kind of jig, is the national dance of England. Captain Cook on his voyages made his sailors dance hornpipes in calm weather to keep them in good health. A characteristic of English dances was that they partook to a great extent of the nature of games; there was little variety in the steps, which were nearly all those of the jig or hornpipe, but these were incorporated into various games or plays, of which the Morris dances were the most elaborate. Richard Baxter wrote that "sometimes the Morris dancers would come into the church in all their linen and scarves and antic dresses, with Morris bells jingling at their legs; and as soon as Common Prayer was read, did haste and presently to their play again." May-day has always been celebrated in England with rustic dances and festivities. Before the Reformation there were no really national dances in use at court; but in the reign of Elizabeth the homely, domestic style of dancing reached the height of its popularity. Remnants of many of these dances remain to-day in the games played by children and country people; "Hunt the Slipper," "Kiss in the Ring," "Here we go round the Mulberry Bush," are examples. All the Tudor dances were kissing dances, and must have been the occasion of a great deal of merriment. Mrs Groves

[2] "A star is lost and appears not in the sky; in thy face it has set itself; on thy brow it shines."

gives the following description of the Cushion Dance:—"The dance is begun by a single person, man or woman, who, taking a cushion in hand, dances about the room, and at the end of a short time stops and sings: 'This dance it will no farther go,' to which the musician answers: 'I pray you, good sir, why say so?' 'Because Joan Sanderson will not come to.' 'She must come to whether she will or no,' returns the musician, and then the dancer lays the cushion before a woman; she kneels and he kisses her, singing 'Welcome, Joan Sanderson.' Then she rises, takes up the cushion, and both dance and sing 'Prinkum prankum is a fine dance, and shall we go dance it over again?' Afterwards the woman takes the cushion and does as the man did." Other popular dances—generally adapted to the tunes of popular songs, the nature of some of which may be guessed from their titles—were the Trenchmore, Omnium-gatherum, Tolly-polly, Hoite cum toite, Dull Sir John, Faine I would, Sillinger, All in a Garden Green, An Old Man's a Bed Full of Bones, If All the World were Paper, John, Come Kiss Me Now, Cuckholds All Awry, Green Sleeves and Pudding Pies, Lumps of Pudding, Under and Over, Up Tails All, The Slaughter House, Rub her Down with Straw, Have at thy Coat Old Woman, The Happy Marriage, Dissembling Love, Sweet Kate, Once I Loved a Maiden Fair. Dancing practically disappeared during the Puritan *régime*, but with the Restoration it again became popular. It underwent no considerable developments, however, until the reign of Queen Anne, when the glories of Bath were revived in the beginning of the 18th century, and Beau Nash drew up his famous codes of rules for the regulation of dress and manners, and founded the balls in which the polite French dances completely eclipsed the simpler English ones. An account of a dancing lesson witnessed by a fond parent at this time is worth quoting, as it shows how far the writer (but not his daughter) had departed from the jolly, romping traditions of the old English dances:—"As the best institutions are liable to corruption, so, sir, I must acquaint you that very great abuses are crept into this entertainment. I was amazed to see my girl handed by and handing young fellows with so much familiarity, and I could not have thought it had been my child. They very often made use of a most impudent and lascivious step called *setting* to partners, which I know not how to describe to you but by telling you that it is the very reverse of *back to back.* At last an impudent young dog bid the fiddlers play a dance called *Moll Patley*, and, after having made two or three capers, ran to his partner, locked his arms in hers, and whisked her round cleverly above ground in such a manner that I, who sat upon one of the lowest benches, saw farther above her shoe than I can think fit to acquaint you with. I could no longer endure these enormities, wherefore, just as my girl was going to be made a whirligig, I ran in, seized my child, and carried her home." What we may call polite dancing, when it became fashionable, soon invaded London, its first home being Madame Cornely's famous Carlisle House in Soho Square. Ranelagh and Vauxhall and Almack's were all extensively patronized, and the rage for magnificent entertainment and dancing culminated in the erection of the palatial Pantheon in Oxford Street—a place so universally patronized that even Dr Johnson was to be found there. White's and Boodle's were also famous assembly rooms, but the most exclusive of all these establishments was Almack's, the original of Brooks's Club.

The only true national dances of Scotland are reels, strathspeys, and flings, while in Ireland there is but one dance—the jig, which is there, however, found in many varieties and expressive of many shades of emotion, from the maddest gaiety to the wildest lament. Curiously enough, although the Welsh dance often, they have no strictly national dances.

Dancing in present-day society is a comparatively simple affair, as five-sixths of almost all ball programmes consists of WALTZES. The origin of the Waltz is a much-debated subject, the French, Italians, and Bavarians each claiming for their respective countries the honour of having given birth to it. As a matter of fact the Waltz, as it is now danced, comes from Germany; but it is equally true that its real origin is French, since it is a development of the *Volte*, which in its turn came from the *Lavolta* of Provence, one of the most ancient of French dances. The *Lavolta* was fashionable in the 16th century, and was the delight of the Valois court. The *Volte* danced by Henry III. was really a *Valse à deux pas*; and Castil-Blaze says that "the waltz which we took again from the Germans in 1795 had been a French dance for four hundred years." The change, it is true, came upon it during its visit to Germany, hence the theory of its German origin. The first German waltz tune is dated 1770—"Ach! du lieber Augustin." It was first danced at the Paris opera in 1793, in Gardel's ballet *La Dansomanie.* It was introduced to English ballrooms in 1812, when it roused a storm of ridicule and opposition, but it became popular when danced at Almack's by the Emperor Alexander in 1816. The Waltz *à trois temps* has a sliding step in which the movements of the knees play an important part. The *tempo* is moderate, so as to allow three distinct movements on the three beats of each bar; and the Waltz is written in 3–4 time and in eight bar sentences. Walking up and down the room and occasionally breaking into the step of the dance is not true waltzing, and the habit of pushing one's partner backwards along the room is an entirely English one. But the dancer must be able to waltz equally well in all directions, pivoting and crossing the feet when necessary in the reverse turn. It need hardly be said that the feet should never leave the floor in the true Waltz. Gungl, Waldteufel, and the Strauss family may be said to have moulded the modern Waltz to its present form by their rhythmical and agreeable compositions. There are variations—chiefly American—which include hopping and lurching steps; these are degradations, and foreign to the spirit of the true Waltz.

The QUADRILLE is a *Contredanse* of some antiquity. The *Contredanse* was first brought to England from Normandy by William the Conqueror, and was common all over Europe in the 16th and 17th centuries. The term Quadrille means a kind of card game, and the dance is supposed to be in some way connected with the game. A species of Quadrille appeared in a French ballet in 1745, and since that time the dance has gone by that name. Like many other dances, it came from Paris to Almack's in 1815, and in its modern form was danced in England for the first time by Lady Jersey, Lady Harriet Butler, Lady Susan Ryder, and Miss Montgomery, with Count Aldegarde, Mr Montgomery, Mr Harley, and Mr Montague. It immediately became popular. It then consisted of very elaborate steps, which in England have been simplified until the degenerate practice has become common of walking through the dance. It can hardly be said to be popular in England to-day. This is a pity, for the Quadrille, properly danced, has many of the graces of the Minuet. It is often stated that the *Contredanse*, or square dance, is of modern French origin. This is incorrect, and probably arises from a mistaken identification of the terms Quadrille and square dance. "Dull Sir John" and "Faine I would" were square dances popular in England three hundred years ago. "Country dance" is a corrupt Anglicization of *contredanse*, and not, as is so often asserted, the true original name of the dance.

The LANCERS were invented by Laborde in Paris in 1836. They were brought over to England in 1850, and were made fashionable by Madame Sacré at her classes in Hanover Square Rooms. The first four ladies to dance the Lancers in England were Lady Georgina Lygon, Lady Jane Fielding, Mdlle Olga de Lechner, and Miss Berkeley.

The POLKA, the chief of the Bohemian national dances, was adopted by Society in 1835 at Prague. Josef Neruda had seen a peasant girl dancing and singing the Polka, and had noted down the tune and the steps. From Prague it rapidly spread to Vienna, and was introduced to Paris by Cellarius, a dancing-master, who gave it at the Odéon in 1840. It took the public by storm, and spread like an infection through England and America. Everything was named after the Polka, from public-houses to articles of dress. Mr Punch exerted his wit on the subject weekly, and even *The Times* complained that its French correspondence was interrupted, since the Polka had taken the place of politics in Paris. The true Polka has three slightly jumping steps, danced on the first three beats of a four-quaver bar, the last beat of which is employed as a rest while the toe of the unemployed foot is drawn up against the heel of the other. The Polka has recently fallen into disuse in England because of the craze for waltzing to every possible and impossible measure.

The GALOP is strictly speaking a Hungarian dance, which became popular in Paris in 1830. But some kind of a dance corresponding to the Galop was always indulged in after *Voltes* and *Contredanses*, as a relief from their grave and constrained measures.

The WASHINGTON POST, PAS DE QUATRE, and several varieties of BARN DANCE are of American origin, and have recently become fashionable. The general tendency of American dances is to be of a lively and romping measure, in which kicking and hopping and waving of the arms take the place of symmetrical figures and rhythmically designed steps.

The POLKA-MAZURKA is extremely popular in Vienna and Buda-Pest, and is a favourite theme with Hungarian composers. The six movements of this dance occupy two bars of 3–4 time, and consists of a mazurka step joined to the polka. It is of Polish origin.

The POLONAISE and MAZURKA are both Polish dances, and are still fashionable in Russia and Poland. Every State ball in Russia is opened with the ceremonious Polonaise.

The SCHOTTISCHE, a kind of modified Polka, was "created" by Markowski, who was the proprietor of a famous dancing academy in 1850. The HIGHLAND SCHOTTISCHE is a fling. The Fling and Reel are Celtic dances, and form the national dances of Scotland and Denmark. They are complicated measures of a studied and classical order in which free use is made of the arms and of cries and stampings. The STRATHSPEY is a slow and grandiose modification of the Reel.

SIR ROGER DE COVERLEY is the only one of the old English social dances which has survived to the present day, and it is frequently danced at the conclusion of the less formal sort of balls. It is a merry and lively game in which all the company take part, men and women facing each other in two long rows. The dancers are constantly changing places in such a way that if the dance is carried to its conclusion everyone will have danced with everyone else. The music was first printed in 1685, and is sometimes written in 2–4 time, sometimes in 6–8 time, and sometimes in 3–9 time.

The COTILLON is a modern development of the French dance of the same name referred to above. It is an extremely elaborate dance, in which a great many toys and accessories are employed; hundreds of figures may be contrived for it, of which the chief are *La Conversation*, *Le Mouchoir*, *La Trompeuse*, *Les Dames Cachées*, *Le Huit entre deux chaises*, *Les Quatre Coins*, *Le Fandango*, *L'Artichaut*, *La Finale*. There are also several figures in which presents, toys, lighted tapers, biscuits, air-balloons, and hurdles are used. Some of these are *Pile ou Face*, *La Parapluie*, *La Pêche à la Ligne*, *La Loterie*, *Le Chevalier de la Triste Figure*, *Les Ballons*, *Steeplechase*, *Le Chasse à Courre*, and *Le Postillon*.

The BALLET is a performance in which dancing, music, and pantomime play equally important parts. The origin of the modern ballet is identical with the revival of dancing, the earliest on record being that given by Bergonzio di Botta at Tortona to celebrate the marriage of the Duke of Milan in 1489. The ballet, like other forms of dancing, was developed and perfected in France; it is closely associated with the history of the opera; but in England it came much later than the opera, for it was not introduced until the 18th century, and in the first Italian operas given in London there was no ballet. During the regency of Lord Middlesex a ballet-master was appointed and a *corps* of dancers formed. The ballet has had three distinct stages in its development. For a long time it was to be found only at the court, when princely entertainments were given to celebrate great occasions. At that time ladies of the highest rank performed in the ballet, and spent much time in practising and perfecting themselves for it. Catherine de' Medici introduced these entertainments into France, and spent large sums of money on devising performances to distract her son's attention from the affairs of the State. Baltasarini, otherwise known as Beaujoyeulx, was the composer of a famous entertainment given by Catherine in 1551 called the "Ballet Comique de la Reyne." This marks an era in the history of the opera and ballet, for we find here for the first time dance and music arranged for the display of coherent dramatic ideas. Henry IV., Louis XIII. and XIV., were all lovers of the ballet and performed various characters in them, and Richelieu used the ballet as an instrument for the expression of political purposes. Lully was the first to make an art of the composition of ballet music, and he was the first to insist on the admission of women as ballet dancers, feminine characters having hitherto been assumed by men dressed as women. When Louis XIV. became too fat to dance, the ballet at court became unpopular, and thus was ended the first stage of its development. It then was adopted in the colleges at prize distributions and other occasions, when the ballets of Lully and Quinault were commonly performed. The third period in the history of the ballet was marked by its appearance on the stage, where it has remained ever since. It should be added that up till the third period dramatic poems had accompanied the ballet, and the dramatic meaning was helped out with speech and song; but with the advent of the third period speech disappeared, and the purely pantomime performance, or *Ballet d'Action*, was instituted. The father of ballet dancing as we know it at the present day was Jean George Noverre, who appeared in 1749. He has left voluminous writings; they are remarkable for a refined literary style, and in them he sets forth at length his theories and practices as an artist of dancing. The *Ballet d'Action* was really invented by him; in fact, the ballet has never advanced beyond the stage to which he brought it; it has rather gone back. Noverre held the opinion that words only served to weaken the action and partly destroy its effects. He held that a pantomime which, in order to be understood, had to borrow the help of a verbal explanation, was imperfect. "When dancers shall feel, and, Proteus-like, transform themselves into various shapes," he says, "to express to the life the

conflict of passions; when their features, their very looks, shall speak their inward feelings; when, extending their arms beyond the narrow circle prescribed by the rigid rules of pedantry, and with equal grace and judgment giving them a fuller scope, they shall by proper situations describe the gradual and successive progress of the passions; when, in fine, they call good sense and genius to the assistance of their art; then they may expect to distinguish themselves: explanatory speeches will become useless; a mute but powerful eloquence will be substituted to much better effect; each motion will be a sentence; every attitude will portray a situation; each gesture convey a thought, and each glance a new sentiment: every part will please, because the whole will be a true and faithful imitation of nature." The essence of Noverre's theory was that mere display was not enough to ensure interest and life for the ballet; and the late Sir Augustus Harris expressed a similar opinion when he was asked wherein lay the reason of the decadence of the modern ballet. Noverre brought to a high degree of perfection the art of presenting a story by means of pantomime, and he never allowed dancing which was not the direct expression of a particular attitude of mind. Since Noverre's time the greatest ballet-master was undoubtedly the famous Gaetano Apolline Baltasare Vestris, who modestly called himself "le dieu de la danse," and was accustomed to say that his century had produced only three great men—himself, Frederic II., and Voltaire. He was, indeed, the finest male dancer that Europe ever produced, and was a great man in his time. Gluck composed *Iphigenia in Aulis* in conjunction with Vestris. In 1750 the two greatest dancers of the day performed together in Paris in a ballet-opera called *Léandre et Héro*; the dancers were Vestris and Madame Camargo, who introduced short skirts on the stage. The word "balette" was first used in the English language by Dryden in 1667, and the first descriptive ballet seen in London was *The Tavern Bilkers*, which was played at Drury Lane in 1702. Since then the ballet in England has been purely exotic and has merely followed on the lines of French developments. The palmy days of the ballet in England are said to have been in the first half of the 19th century, when there was a royal revenue spent on the maintenance of this fashionable attraction. Some famous dancers of this period were Carlotta Grisi, Mdlle Taglioni (who is said to have turned the heads of an entire generation), Fanny Elssler, Mdlle Cerito, Miss P. Horton, Miss Lucile Grahn, and Mdlle Carolina Rosati. Miss Kate Vaughan is probably the greatest dancer whom England has produced, and, in Sir Augustus Harris's opinion, she did much to elevate the modern art. She was the first to make skirt-dancing popular, although that achievement will not be regarded as an unmixed benefit by every student of the art. Skirt-dancing, in itself a beautiful exhibition, is a departure from true dancing in the sense that the steps are of little importance in it; and in the present day we have seen its development extend to a mere exhibition of whirling draperies under many coloured lime-lights. The best known of Miss Vaughan's disciples and imitators (each of whom has contributed something to the art on her own account) have been Miss Sylvia Grey, Miss Letty Lind, Miss St Cyr, Miss Mabel Love, and Miss Topsy Sinden. But ballet-dancing, affected by a tendency in modern entertainment to make less and less demands on the intelligence and intellectual appreciation of the public, and more and more demands on the eye,—the sense most easily affected,—has gradually developed into a spectacle, the chief interest of which is quite independent of dancing. Thousands of pounds are spent on dressing a small army of women who do little but march about the stage and group themselves in accordance with some design of colour and mass; and no more is asked of the intelligence than to believe that a ballet dressed, for example, in military uniform is a compliment to or glorification of the army. Only a few out of hundreds of members of the *corps de ballet* are really dancers, and they perform against a background of colour afforded by the majority. It seems unlikely that we shall see any revival of the best period and styles of dancing until a higher standard of grace and manners becomes fashionable in Society. With the constantly increasing abolition of ceremony, courtliness of manner is bound to diminish; and only in an atmosphere of ceremony, courtesy, and chivalry can the dance maintain itself in perfection.

(A. B. F. Y.)

**Danube.**—The river Danube and its tributaries have been described at length in the ninth edition of the *Encyclopædia Britannica*. It is proposed in this article to describe briefly the recent engineering works for the improvement of its navigation, more especially those that have been carried out under international agreement as decided on under the Treaties of Paris, Berlin, and London.

***European Commission.***

The European Commission in 1866 had its powers prolonged for five years, and by the Treaty of London of 1871 it was granted another twelve years' lease of life. At the Congress of Berlin in 1878 its jurisdiction was extended from Isakcha upwards to Galatz, a distance of 25 nautical miles, and it was decided that Rumania should henceforward be represented by a delegate. By the Treaty of London of 1883 the jurisdiction of the Commission was extended from Galatz to Braila—10 miles farther up the river; and its powers were prolonged for twenty-one years (*i.e.* till the 24th of April 1904), at the expiration of which period its existence is to continue by tacit prolongation for successive terms of three years, unless one of the High Contracting Powers should propose any modification in its constitution or attributes. It was also decided to withdraw the Kilia or Northern branch of the mouths of the Danube from the immediate jurisdiction of the European Commission, but Russia and Rumania were to superintend the application of the regulations in force in the Sulina branch in that part of the Kilia branch lying between those countries. Russia was given complete control over that portion of the river which flows exclusively through her own territory, and was authorized to levy tolls intended to cover the expenses of any works of improvement that might be undertaken by her. Article VII. of the same Treaty declared that the regulations for navigation, river police, and superintendence drawn up on the 2nd of June 1882 by the European Commission, assisted by the delegates of Servia and Bulgaria, should be made applicable to that part of the Danube situated between the Iron Gates and Braila. In consequence of Rumania's opposition, the Commission Mixte was never formed, and these regulations have never been put in force. As regards the extension of the Powers of the European Commission to Braila, 10 miles above Galatz, and at the head of the Maritime Navigation, a tacit understanding has been arrived at, under which questions concerning navigation proper come under the jurisdiction of the Commission, while the police of the ports remains in the hands of the Rumanian authorities.

The British delegates on the Commission have been successively:—Sir John Stokes, R.E., K.C.B., whose invaluable services extended over a period of fifteen years, from 1856 to 1871; General C. G. Gordon, R.E. (of Khartum), from 1871 to 1873; Major-General H. T. Siborne, R.E., from 1873 to 1881; Sir Percy Sanderson, K.C.M.G., 1882 to 1894; and Lieutenant-Colonel Henry Trotter, R.E., C.B., since October 1894.

In the ninth edition of the *Encyclopædia Britannica* it was stated, as regards the work effected by the European Commission of the Danube, that between 1858 and 1871 the depth of water at the entrance of the Sulina Port had been increased from 9 to 19 feet. In 1876 the south jetty was prolonged, so as to bring its end exactly opposite the lighthouse on the north pier. This resulted in an increase of the depth to 20½ feet, and for fifteen years, from 1879 to 1895, this depth remained constant without the aid of dredging. In 1894, owing to the constantly increasing size of vessels frequenting the Danube, it was found necessary to deepen the entrance still farther, and to construct two parallel piers between the main jetties, reducing the breadth of the river to 500 feet, and thereby increasing the scour. There is now a continuous channel 5200 feet in length and 24 feet in depth, 300 feet in width between the piers and 600 feet in width outside the extremities of the piers, until deep water is reached in the open sea.

***Improvements.***

In addition to the successful treatment of the main Danube 11 miles below Isakcha, the engineers of the Commission have been equally successful in dealing with the Sulina branch of the river. Its original length of 45 miles from St George's Chatal to the sea was impeded at the commencement of the improvement works by eleven bends, each with a radius of less than 1000 feet, besides numerous others of somewhat larger radius, and its bed was encumbered by ten shifting shoals, varying from 8 to 13 feet in depth at low water. By means of a series of training walls, by groynes thrown out from the banks, by revetments of the banks, and by dredging, all done with the view of narrowing and limiting the breadth of the river, a minimum depth of 11 feet was attained in 1865, and 13 feet in 1871. In 1880 the needs of commerce and the increased size of steamers frequenting the river necessitated the construction of a new entrance from the St George's branch. This work, designed in 1857, but unexecuted during a quarter of a century, owing to insufficiency of funds, was completed in 1882; and in 1886, after other comparatively short cuttings had been made to get rid of difficult bends and further to deepen the channel without having to resort to dredgers, the desired minimum depth of 15 feet was attained. Since that date a series of new cuttings have been made, the last commenced in 1898, and estimated to be completed in 1902. These new cuttings, when the last is completed, will have shortened the length of the Sulina canal by 11 nautical miles, eliminated all the difficult bends and shoals, and provided an almost straight waterway 34 miles in length from Sulina to the St George's Chatal, with a minimum depth of 18 feet when the river is at its lowest.

Two names are indissolubly connected with the eminently satisfactory results obtained both in the river and at its mouth. The English engineer Sir Charles Hartley designed all the works and improvements referred to, and personally superintended their execution from 1856 until 1872, after which time he occupied the post of consulting engineer, while the execution of the works after 1872 devolved on the Danish engineer, Mr Charles Kuhl.

***Finance.***

The Commission has an average annual income of about £80,000, derived from taxes paid by ships when *leaving* the river. The normal annual expenditure amounts to about £56,000, while £24,000 is generally allotted to extraordinary works, such as new cuttings, &c. This large expenditure has, however, been attended with a more than corresponding benefit to commerce. The depth of water over the bar of the Sulina mouth has been increased from 9 feet (in 1856) to the minimum of 24 feet (in 1900). The minimum depth of water in the Sulina branch with the river at its lowest has been increased during the same period from 8 feet to 17 feet. Freights from Galatz and Braila to North Sea ports have fallen from 50s. to about 12s. 6d. per ton. Sailing ships of a maximum of 200 tons register have given way to steamers up to 2600 tons register carrying a dead weight of 5500 tons; and last, but not least, good order has succeeded chaos.

As illustrating the great value, especially to British maritime trade, of the improvements that have been effected by the Danube Commission in the navigable channel of the river from Braila to the sea, it may be mentioned that whilst from 1857 to 1867 the average annual registered tonnage entered was but 450,000 tons, of which only one-third was British, the total tonnage in 1896 had increased to 1,800,000, of which three-fifths was British. Thus in thirty years the whole annual Danubian trade of all European nations increased fourfold, while the tonnage of British ships increased eightfold.

In 1861 the average size of the 3084 vessels visiting the river was 146 tons register only, whereas in 1899–1900 the average size exceeded one thousand tons register.

***Iron Gates.***

Many of the treaties previously alluded to also dealt with the question of the regularization of that part of the Danube lying between Old Moldowa (in Hungary) and Turn-Severin (Rumania). Article VI. of the Treaty of London (1871) authorizes the Powers which possess the shores of that part of the Danube where the cataracts and the Iron Gates offer impediments to navigation, to come to an understanding with the view of removing these impediments, and to have the right of levying a provisional tax on vessels of every flag which may henceforth benefit thereby until the extinction of the debt contracted for the execution of the works. As the riverain Powers could not come to an agreement on the subject, the Great Powers at the Congress of Berlin (1878) intrusted to Austria-Hungary the execution of the works in question. Austria-Hungary subsequently conferred its rights on Hungary, by whom the works were carried out at the cost of about 1½ millions sterling.

For the construction of the works and the formation of a sinking fund by which the capital expenditure will be repaid in ninety-nine years, the Hungarian Government raised a loan of 22½ millions of florins, the interest on this sum, together with the annual expenditure in repairs, maintenance, pilotage, &c., is estimated to amount to 900,000 florins, and the Hungarians claim that the difference between this sum and the estimated revenue, *i.e.*, 500,000 florins, is a generous contribution paid by Hungary for the benefit of navigation in general. The engineering works in the neighbourhood of the Iron Gates are of great interest. The principal obstructions between Old Moldova and Turn-Severin are the Stenka Rapids, the Kozla Dojke Rapids, the Greben section, and the Iron Gates. At the first named there was a bank of rocks, some of them dry at low water, extending almost across the river (985 yards wide). The fall of the river-bed is small, but the length of the rapid 1100 yards. The Kozla Dojke, 9 miles below the Stenka Rapids, extend also for 1100 yards, with a fall 1 in 1000, and are caused by the two banks of rocks which cause a sudden alteration in the direction of the current. The river is here only 170 to 330 yards in width; 6 miles below them is the Greben section, the most difficult part of the works of improvement. A spur of the Greben mountains runs out below two shoals into the river, which suddenly narrows to about 300 yards at low water, although it shortly widens to 1½ miles. Seven miles lower down are the Juez Rapids, where the river-bed has a fall of 1 in 433. At the so-called Iron Gates, between Orsova and Turn-Severin, and 34 miles below the Greben, the Prigrada rocky bank nearly blocked the river at the point where it widens out after leaving the stupendous Kazan defile.

During the 19th century many schemes were worked out for the improvement of this portion of the river, but it was not till 1883 that a practical start was made, and the Hungarian engineers, Messrs Vásárhalyi and Wallandt, prepared the designs which have since been executed. The general object of these works was to give a navigable depth of water at all seasons of 2 metres (6½ feet) on that portion of the river above Orsova, and a depth of 3 metres below that town. To effect this at Stenka, Kozla Dokje, Izlas, and Gachtalia, channels 66 yards wide had to be cut in the solid rock to a depth of 6 feet 6 inches below low water. The point of the Greben spur had to be entirely removed for a distance of 167 yards back from its original face (in the execution of which work in 1894 no less than 2,100,000 cubic feet of rock were thrown down by a single charge of 12 tons of dynamite). Below the Greben point a training wall 7 to 9 feet high, 10 feet at top, and nearly 4 miles in length, has been built along the Servian shore in order to confine the river in a narrow channel. At Juez another similar channel had to be cut and a training wall built. At the Iron Gates a channel 80 yards wide and nearly 2000 yards in length (1720 metres) had to be cut on the Servian side of the river, traversing the Prigrada Bank to a depth of 9 feet 9 inches below high-water level. Training walls have been built on either side of the channel to confine the water so as to raise its level; that on the right bank having a width of 19 feet 6 inches at top, and serving as a tow-path; that on the left being 13 feet in width. These training walls are built of stone with flat revetments to protect them against ice.

***General results.***

These formidable and expensive works have not altogether realized the expectations that had been formed of them. One most important result, however, has been attained, *i.e.*, vessels can now navigate the Iron Gates at all seasons of the year when the river is not closed by ice, whereas formerly at extreme low water, lasting generally for about three months in the late summer and autumn, through navigation was always at a standstill, and goods had to be landed and transported considerable distances by land. The canal was opened for traffic on the 1st October 1898, and during the last three months of that year 180,000 tons of merchandise was carried through the canal out of a total traffic during the year of 500,000 tons. On the other hand, the canal was designed of sufficient width, as was supposed, for the simultaneous passage of boats in opposite directions; but on account of the great velocity of the current, this has been found to be dangerous and impracticable. The slope of the stream at the upper entrance of the canal is from 1 in 200 to 1 in 300, according to the height of the water, producing a velocity varying from 16 to 19½ feet per second, and so lowering the surface of the water that when the river is at its lowest the depth of water in the canal

varies from $7\frac{1}{2}$ to 8 feet only. Similar and other causes, such as the discovery of fresh banks at the island of Ada Kaleh, have produced similar effects higher up the river. Between the Iron Gates and Orsova, at extreme low water, *i.e.*, when the gauge at Orsova reads zero, there is only 3 feet 6 inches of available depth, *i.e.*, at certain seasons 9 inches less than before the works of improvement were commenced. Again, between Orsova and Old Moldova, at extreme low water there is a navigable depth of only 3 feet instead of the anticipated 6 feet 6 inches. It was calculated, however, that with three more years' work and a further expenditure of £240,000, the wished-for depth of 6 feet 6 inches would be obtained throughout the whole distance from Old Moldova to the Iron Gates.

In addition to the works already described, executed under international arrangements, the riverain Powers—Bavaria, Austria, and Hungary—have spent large sums of money in improving the navigation of the Upper Danube. At Vienna the principal channel of the Danube was brought $1\frac{1}{2}$ miles nearer the town by the construction of a new channel 10 miles in length and 330 yards in breadth, with a depth at low water of from 10 to 11 feet. This work, projected in 1866, involved the removal of 12 million cubic metres of sand and gravel, and with its subsidiary works, bridges, quays, &c., cost about $3\frac{1}{4}$ millions of pounds sterling. It has proved an immense success, not only protecting Vienna from disastrous inundations, the principal object in view, but also in improving the railway communication and the navigability of the river.

Very extensive engineering operations have also been carried out at Buda-Pest, where the Soroksar branch of the Danube, which in time of flood carried away one-third of its entire volume of water, has been completely closed, the water passing into the main Promontor channel.

The result of all the combined works for the rectification of the Danube is that from Sulina up to Braila the river is navigable for seagoing vessels of 2500 tons register. From Braila to Turn-Severin it is open for seagoing vessels up to 600 tons, and for flat barges of from 1500 to 2000 tons capacity. From Turn-Severin to Orsova navigation is confined to river steamers, tugs, and barges drawing 6 feet of water. Thence to Vienna the draught is limited to 5 feet, and from there to Ratisbon to a somewhat lower figure. Barges of 600 tons register can be towed from the Lower Danube to Ratisbon, at which place petroleum tanks have been constructed for the storage of Rumanian petroleum, the first consignment of which in 1898, conveyed in tank boats, took six weeks on the voyage up from Giurgevo. The principal navigation company on the Upper Danube is the Société Impériale et Royale Autrichienne of Vienna, which started operations in 1830 with three small steamers, but now possesses a fleet of 151 paddle steamers, 23 screw steamers, 5 powerful tugs, and 850 large barges, besides grain elevators, dredgers, steam launches, &c. &c. In 1896 they carried 579,000 passengers for long distances, 2,220,000 for short distances, 1,113,871 tons of miscellaneous cargo, 978,000 tons of cereals, and 148,609 tons of coal. Their gross receipts during the same year were $14\frac{3}{4}$ million florins. The company transports goods and passengers between Galatz and Ratisbon.

A less important society is the Rumanian State Navigation Company, possessing a large flotilla of tugs and barges, which run to Buda-Pest, where they have established a combined service with the South Danube German Company for the transport of goods from Pesth to Ratisbon. A Hungarian Navigation Company, subsidized by the State, has recently been formed, and the Hungarian railways, the Servian Government, and private owners own between them about 70 tugs and 420 barges of about 380,000 tons burden.

The merchandise carried in 1896 between Sulina and the Iron Gates and intermediate ports amounted to 3,529,575 tons, of which 2,700,000 tons was composed of cereals and the remainder miscellaneous merchandise. Three-fourths of this amount were carried down stream, and one-fourth up.

The following tables show the total amount of tonnage (registered) of ships leaving the Danube and clearing for foreign ports at quinquennial intervals from 1871 to 1896, and for each year from 1889 to 1900 :—

*Quinquennial Returns.*

| Year. | Total Tonnage. | British Tonnage. | Proportion of British to whole. |
|---|---|---|---|
| | | | Per cent. |
| 1871 . . . | 549,720 | 178,858 | 32·54 |
| 1876 . . . | 748,363 | 452,414 | 60·45 |
| 1881 . . . | 793,454 | 498,994 | 62·88 |
| 1886 . . . | 950,567 | 623,479 | 65·59 |
| 1891 . . . | 1,512,030 | 990,935 | 65·53 |
| 1896 . . . | 1,794,934 | 1,097,689 | 62·00 |

*Annual Returns.*

| Year. | Total Number of Vessels. | Total Tonnage. | Number of British Vessels. | Tonnage. | Per cent. |
|---|---|---|---|---|---|
| 1889 | 1870 | 1,473,345 | 842 | 1,000,773 | 67·93 |
| 1890 | 1828 | 1,539,445 | 778 | 983,862 | 63·91 |
| 1891 | 1723 | 1,512,030 | 773 | 990,935 | 65·53 |
| 1892 | 1532 | 1,427,087 | 638 | 866,758 | 60·73 |
| 1893 | 1801 | 1,893,506 | 905 | 1,287,762 | 68·00 |
| 1894 | 1716 | 1,619,703 | 733 | 1,034,097 | 63·84 |
| 1895 | 1619 | 1,554,698 | 604 | 906,043 | 58·27 |
| 1896 | 1713 | 1,794,934 | 699 | 1,097,737 | 61·15 |
| 1897 | 1324 | 1,397,917 | 540 | 855,477 | 61·19 |
| 1898 | 1419 | 1,476,119 | 446 | 694,773 | 47·06 |
| 1899 | 1056 | *1,070,367 | 277 | 446,170 | 41·68 |
| 1900 | 1101 | 1,252,509 | 260 | 458,921 | 36·64 |

* This diminution was due to failure of the harvest in Rumania and Bulgaria.

(H. TR)

**Danvers,** a town of Essex county, Massachusetts, U.S.A. It includes an area of 14 square miles of level country diversified by glacial hills, with a village bearing the same name, and a large rural population. It is traversed by a branch of the Boston and Maine Railway. The village is irregular in plan, contains a State Insane Asylum and a public library, and has manufactures of boots and shoes, leather, &c. Population (1880), 6598; (1890), 7454; (1900), 8542.

**Danville,** capital of Vermilion county, Illinois, U.S.A., on the Vermilion river, at an altitude of 598 feet. Its site is a level prairie, and its street plan is regular. It is entered by three railways, the Chicago, and Eastern Illinois, the Cleveland, Cincinnati, Chicago and St Louis, and the Wabash. Situated in a coal-mining region, it handles and ships large quantities of that commodity. It contains also car shops and ironworks. Population (1880), 7733; (1890), 11,491; (1900), 16,354.

**Danville,** capital of Boyle county, Kentucky, U.S.A., on the Queen and Crescent Railway, at an altitude of 955 feet. It is the seat of Centre College, opened in 1821, and of Caldwell College for women, both Presbyterian institutions, and of the State Deaf and Dumb Institute. Population (1880), 3074; (1890), 3766; (1900), 4285.

**Danville,** capital of Montour county, Pennsylvania, U.S.A., in 40° 58′ N. lat. and 76° 37′ W. long., on the north branch of the Susquehanna, at an altitude of 471 feet. The borough is irregular in plan, though situated on a level plain. It is on the Delaware, Lackawanna, and Western, and the Philadelphia and Reading Railways. It is of importance because of its iron manufactures. Population (1880), 8346; (1890), 7998; (1900), 8042.

**Danville,** a city of Virginia, U.S.A. Though within the limits of Pittsylvania county, it is not subject to county organization. It is on the Danville river, at the falls, near the southern boundary of the state, at an altitude of 413 feet, and is traversed by the Southern and the Danville and Western Railways. It is the seat of Roanoke Female College. The city has long been prominent in the tobacco trade, and in the manufacture of smoking and chewing tobacco. It is also becoming important in the manufacture of cotton. Population, including the annexed town of North Danville (1880), 8726; (1890), 14,104; (1900), 16,520.

**Danzig,** a strong maritime fortress and seaport town of Prussia, capital of the province of West Prussia, headquarters of the 17th German Army Corps, standing on the Vistula, 3 miles south of its entrance into the Baltic. The

old fortifications, which, with their twenty-two bastions, surrounded the inner town, were taken down on the west and north sides in 1895–96. The trenches have been filled in, and the area thus freed has been laid out on a spacious plan. One portion, acquired by the corporation, has been turned into promenades and gardens, the New Steffens Park, 50 acres in extent, outside the Olivner Thor, occupying the north-western corner. The remainder of the area remains in the hands of the military authorities. A cordon of detached forts has lately been built for the defence of the harbour, which is now strongly protected against attack from the sea. The natural history and archæological collections of the West Prussian Museum are preserved in the Green Gate; the provincial industrial museum and the municipal picture gallery in a former Franciscan monastery. The most recent public buildings are the extensive slaughter-houses, the market-hall, the imperial post office, a new railway station, and a new Evangelical church. The educational and similar institutions embrace a military school, an art and a technical school, a school of navigation, a commercial academy, and a couple of observatories; whilst a technical high school was built in 1900–01. Danzig owed its commercial importance to the fact that it was the shipping port for the corn grown in Poland, and the adjacent regions of Russia and Prussia; but for some few years past this trade has been slipping away from her. On the other hand, her trade in timber and sugar has grown proportionally. Nevertheless energetic efforts are being made to check any loss of importance—first, in 1898, by a determined attempt to make Danzig an industrial centre, manufacturing on a large scale; and secondly, by the construction, and opening in 1899, of a free harbour at the mouth of the Vistula. The industries which it has been principally aimed to establish are shipbuilding (naval and marine), steel foundries and rolling mills, sugar refineries, flour and oil mills, and distilleries. The free port at Neufahrwasser, at the mouth of the Vistula, has a total area of 39½ acres. Vessels drawing 16½ feet can, however, get up to the wharves of Danzig itself, the approach being kept open in winter by ice-breakers. The port is cleared by an average of 1433 vessels of 481,000 tons annually (1712 vessels of 651,821 tons in 1899), a decrease as compared with 1805 vessels of 796,065 tons cleared in 1884. The exports reach an average of £4,972,150 annually (£3,230,000 in 1884); whilst the imports, chiefly coal, average £4,219,700 annually (£2,960,000 in 1884). The mercantile fleet of Danzig numbered, in 1900, 49 seagoing vessels of some 26,956 tons. Population (1885), 114,805; (1895), 125,605; (1900), 140,539.

**Darbhanga,** a town and district of British India, in the Patna division of Bengal. The town is on the left bank of the Little Baghmati river, and has a railway station. The population in 1881 was 65,955; in 1891 it was 73,561; and in 1901 it was 65,990. The town is really a collection of villages that have grown up round the residence of the Raja, who ranks as the first nobleman of Behar. This is now a magnificent palace, with gardens, a menagerie, and a good library. There are a first-class hospital, with a Lady Dufferin hospital attached; a handsome market-place; an Anglo-vernacular school; and four printing-presses.

The DISTRICT OF DARBHANGA lies in North Behar, extending from the Nepal frontier to the Ganges. It was constituted in 1875 out of the unwieldy district of Tirhut. Its area is 3335 square miles. The population in 1881 was 2,630,496; in 1891 it was 2,801,955, giving an average density of 840 persons per square mile. Classified according to religion, Hindus numbered 2,462,308; Mahomedans, 338,667; Christians, 380, of whom 200 were Europeans; "others," 600. In 1901 the population was 2,914,577, showing an increase of 4 per cent. The land revenue and rates were Rs.10,51,273; the number of police was 471; the number of boys at school in 1896–97 was 31,410, being 15·2 per cent. of the male population of school-going age; the registered death-rate in 1897 was 27·36 per thousand. There are 30 indigo factories, with a capital of Rs.61,36,000, employing 26,000 hands, and producing an out-turn valued at Rs.15,00,000; 54 saltpetre refineries; and a tobacco factory, producing cigars valued at Rs.37,000. The district is traversed by the main line and branches of the Tirhut State Railway, originally begun as a famine relief work in 1874.

**Dardanelles** (Town) [*Sultanieh Kalehsi*, or *Chanak Kalehsi*, of the Turks], the chief town and seat of government of the lesser Turkish province of Bigha, Asia Minor. It is situated at the mouth of the Rhodius, and at the narrowest part of the Strait of the Dardanelles, where its span is but a mile across between the continents of Europe and Asia. Its recent growth has been rapid, and it possesses a lyceum, a military hospital, a public garden, a theatre, quays, and water-works, besides many private houses and a suburb. Exclusive of the garrison, the population is estimated at 13,000, of whom one-half are Turkish, and the remainder Greek, Jewish, Armenian, and European. The town contains many mosques; Greek, Armenian, and Catholic churches; and a synagogue. There is a resident Greek bishop. Strategically the Dardanelles is a point of great importance, since it commands the approach to Constantinople from the Mediterranean. The civil governor, and the military commandants of the numerous fortresses on each side of the Strait, are stationed here. Many important works have been added to the defences. Armed with modern artillery and protected by torpedoes, the forcing of the passage would be a difficult operation. The Ottoman Fleet is stationed not far from the town, at Abydos, now called Nagara. The average annual number of merchant vessels passing the Strait is 12,000, and the regular commercial vessels calling at the port of Dardanelles are represented by numerous foreign agencies. Besides the Turkish telegraph service, the Eastern Telegraph Company has a station at Dardanelles, and there are Turkish, Austrian, French, and Russian post offices. The import trade consists of manufactures, sugar, flour, coffee, rice, leather, and iron. The export trade consists of valonia (largely produced in the province), wheat, barley, beans, chick-peas, canary seed, liquorice root, pine and oak timber, wine, and pottery. Excepting in the items of wine and pottery, the export trade shows steady increase. Immigration brings a larger area of land under cultivation year by year, and every year adds to the number of mature (*i.e.*, fruit-bearing) valonia trees. Vine-growers are discouraged by heavy fiscal charges, and by the low price of wine. Many are uprooting their vineyards. The pottery trade is affected by change of fashion, and the old potteries of *Chanak* Kalehsi are losing their importance. The lower quarters of the town were heavily damaged in the winter of 1900–1 by repeated inundations caused by the overflow of the Rhodius. (E. W*.)

**Dar el Baida** (in English, *White House;* in Spanish, *Casa Blanca*), a growing grain port of Central Morocco, with numerous foreign merchants, Franciscan and Protestant missions, and a consular corps. Exports: 1896, £197,131; 1897, £212,824; 1898, £281,247. Imports: 1896, £175,788; 1897, £176,713; 1898, £211,461. Shipping: 1897, 155,315 tons; 1898, 150,048 tons. Population, probably about 20,000.

**Darial,** a widely renowned gorge in the Caucasus, through which the Terek pierces, for a distance of 8 miles, between vertical walls, the Side Range of the Caucasus. It is fortified at its northern entrance. It was known to Pliny and to Procopius, and mentioned in the Georgian annals under the names of Ral-ani, Dargani, Darialani, &c., of which the root is the Persian *dar* or *der*, meaning "door." The Persians and the Arabs knew it as the Gate of the Alans. Being the only available passage across the Caucasus, it was fortified since a remote antiquity, at least in 150 B.C. In Russian poetry it has been immortalized by Lermontoff. The present Russian fort, Darial, is at the northern issue of the gorge, at an altitude of 4122 ft.

**Darjiling,** a hill station and district of British India, in the Rajshahi division of Bengal. The sanitary station is situated 367 miles by rail north of Calcutta. In 1881 it had a population of 7018, and in 1891 of 14,145. It is now the summer quarters of the Bengal Government. There are several schools of considerable size for European boys and girls, and the Government boarding-school at Kurseong can accommodate 200 boys. Three breweries have an out-turn of 80,000 gallons. The buildings and the roads suffered severely from the earthquake of June 12, 1897. But a more terrible disaster occurred in October 1899, when a series of landslips carried away houses and broke up the hill railway. The total value of the property destroyed was returned at Rs.25,00,000.

The DISTRICT comprises an area of 1164 square miles. The population in 1881 was 155,645, and in 1891 was 223,314, giving an average density of 192 persons per square mile. Classified according to religion, Hindus numbered 171,171; Mahommedans, 10,011; Buddhists, 40,600; Christians, 1502, of whom 1049 were Europeans; "others," 30. In 1901 the population was 249,232, showing an increase of 12 per cent., compared with an increase of 43 per cent. in the previous decade. The land revenue and rates were Rs.1,65,806; the number of police was 395; the number of boys at school in 1896–97 was 2938, being 15·9 per cent. of the male population of school-going age; the registered death-rate in 1897 was 42·16 per thousand. The cultivation of tea was introduced in 1856. In 1897 there were 186 gardens, with 55,822 acres under tea, employing 32,897 persons permanently and 14,108 persons temporarily, and producing nearly 12 million ℔. Cinchona cultivation was introduced by the Government in 1862, and has since been taken up by private enterprise. In 1896–97 the number of plants in the Government plantations was nearly 2½ millions; and the amount of dry bark produced was 318,715 ℔. Including bark bought from private plantations, the out-turn of the Government factory was 10,149 ℔ of sulphate of quinine, and 4075 ℔ of cinchona febrifuge; the gross receipts were Rs.1,76,798, and the net profits Rs.9767. The three forest divisions of Darjiling yielded in that year a gross revenue of Rs.1,36,058. There is a coal-mine at Daling, employing 260 persons, with an output of 2000 tons. The Darjiling Himalayan Railway of 2 feet gauge, opened in 1880, runs for 50 miles from Siliguri in the plains on the Eastern Bengal line.

See G. S. BOMWETSCH. *A Handbook to Darjiling and its Railway.* Calcutta, 1899.

**Darlington,** a municipal and parliamentary borough (one member) and market-town of Durham, England, on the Skerne, 1 mile from its confluence with the Tees, 18 miles south of Durham city by rail. There are now, in all, seven Established churches, two Roman Catholic churches and a school chapel, and twelve Nonconformist churches or chapels. The training-school for schoolmistresses has been enlarged and a school for children added. Recent erections are a cattle market, a corn exchange, hospital, library, and new theatre. A technical school has been formed, the public park enlarged to an area of 44 acres, and the baths twice extended. The worsted spinning mills of Pease & Company have upwards of 18,000 spindles, and employ between 500 and 600 hands. The Pease Partners Company (Limited) employ at their collieries, ironstone mines, quarries, brickworks, &c., over 6000 workmen, and raise about 3,000,000 tons of minerals per annum. Darlington possesses important works for the manufacture of iron and steel bars, and the specialties required for engineering, bridge-building, ship-building, locomotive engine-work, railway waggon building, collieries, &c. At the Rise Carr Rolling Mills (belonging to Sir Theodore Fry & Company, Limited) about 700 men are employed, and in 1899 the output of finished iron and steel work amounted to 25,840 tons. The Darlington Forge Company (Limited), with premises of 100 acres in area, of which about 40 acres were in 1901 occupied by their rapidly extending works, employ from 1000 to 1200 men, and, besides turning out steel castings and steel and iron forgings for engineering purposes, manufacture gun work, shells, &c., for British and foreign shipyards and arsenals; the annual output, of all descriptions, being from 10,000 to 12,000 tons, representing a value of about £250,000.

Extended municipal area, 3945 acres. Population on this in 1881, 35,104; in 1891, 38,060; in 1901, 44,496. Parliamentary area since 1885, 3602 acres. Population on this in 1881, 34,831; in 1891, 38,033; in 1901, 44,496. Rateable value of municipal borough in 1900, £183,725.

**Darmesteter, James** (1849–1894), author and antiquarian, was born of Jewish parents on 28th March 1849. He was educated at Paris, where, under the guidance of M. Michel Bréal, he imbibed a love for Oriental studies, to which for a time he entirely devoted himself. In 1875 he published a thesis on the mythology of the Zendavesta, and in 1877 became university professor of Zend. He followed up his researches with his *Études Iraniennes* (1883), and ten years later published a complete translation of the Avesta, with commentary, in the *Musée Guimet*. An interesting episode in his life was his journey to India in 1886, undertaken for the purpose of collecting the popular songs of the Afghans, a translation of which, with a valuable essay on the Afghan language and literature, he published on his return. His impressions of English dominion in India were conveyed in *Lettres sur l'Inde* (1888). England interested him deeply; his attachment for a gifted English poetess, whom he eventually married, led him to translate the poems of Mary Robinson; and two years after his death a collection of excellent essays on English subjects was published in English. He also wrote *Le Mahdi*, *Origine de la Poësie Persane*, *Prophètes d'Israel*, and other books on topics connected with the East, and from 1883 onwards drew up the annual reports of the Société Asiatique. He had just become connected with the *Revue de Paris*, a new undertaking of great importance, when his delicate constitution succumbed to a slight attack of illness on 19th October 1894. (R. G.)

**Darmstadt,** a town of Germany, capital of grand-duchy of Hesse-Darmstadt, 21 miles by rail south-east from Mainz and 17 miles south from Frankfort-on-Main. Here are a technical high school, possessing (since 1900) power to confer the degrees of doctor of engineering (doctor of the technical sciences in Prussia), a school of agriculture, an artisans' school, and a botanical garden. The chemist von Liebig was born in Darmstadt in 1803. Principal industries: the production of machinery, carpets, playing

cards, chemicals, tobacco, hats, wine, and beer. In 1888 Bessungen was incorporated with Darmstadt. Population (1885), 50,609; (1895), 63,745; (1900), 72,019 (provisional census results).

**Darrang,** a district of British India, in the Brahmaputra Valley division of Assam. It lies between the Bhutan and Dafla Hills and the Brahmaputra, including many islands in the river. The administrative headquarters are at Tezpur. Its area is 3418 square miles. The population in 1881 was 273,333; in 1891 it was 307,761, giving an average density of 90 persons per square mile. Classified according to religion, Hindus numbered 196,037; Mahommedans, 18,454; hill tribes, 91,870; Christians, 849, of whom 183 were Europeans; "others," 551. In 1901 the population was 337,724, showing an increase of 10 per cent. The land revenue was Rs.7,15,656, the incidence of assessment being Rs.2–10–2 per acre; the number of police was 195; the number of boys at school in 1896–97 was 4114, being 17 per cent. of the male population of school-going age; the registered death-rate in 1897 was 45·68 per thousand. In 1897 the number of tea gardens was 89, with 33,984 acres under tea, employing 71,535 persons, of whom 23,424 were children, and producing an out-turn of over 11 million ℔, or at the rate of 407 ℔ per acre. There is a timber mill, producing 25,000 tea-chests, valued at Rs.20,000. Almost the only means of communication is by river. A steam tramway of 2½ feet gauge has been opened from Tezpur to Balipara, a distance of 20 miles. A similar tramway is proposed at Mangaldai, with a length of 35 miles.

**Dartford,** a market-town in the Dartford parliamentary division of Kent, England, on the Darenth, 16 miles east-south-east of London by rail. Recent erections are a Martyrs' Memorial Hall and a cottage hospital. On Dartford Heath is the lunatic asylum of the London County Council, and, at Long Reach, the infectious diseases hospital of the Metropolitan Asylums Board. Iron, chemical, and cement works have been introduced. Area of parish (an urban district), 4251 acres. Population (1881), 10,163; (1891), 11,962; (1901), 18,615; of parliamentary division (1891), 79,853.

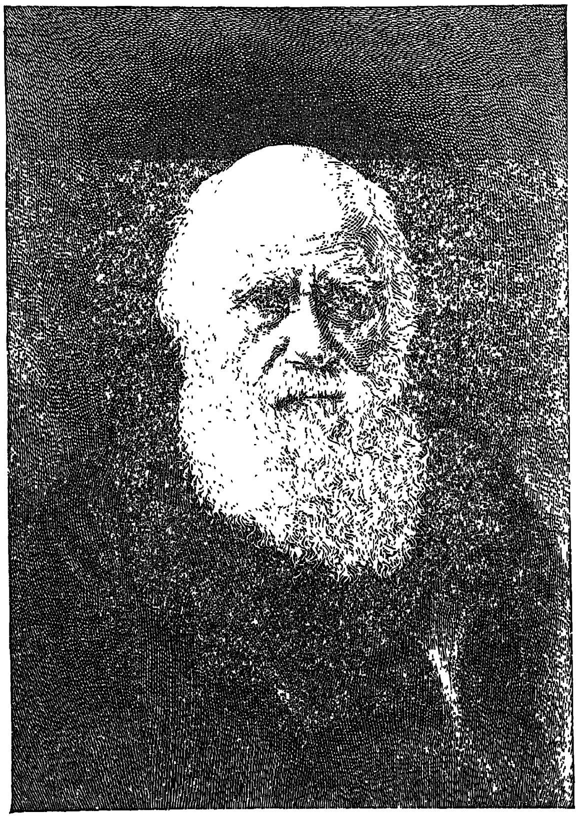
**Dartmouth,** a municipal borough, seaport, and market-town in the Torquay parliamentary division of Devonshire, England, on the west side of the estuary of the Dart, 28 miles east of Plymouth. The town is connected with the Great Western Railway by a steam ferry to Kingswear on the opposite side of the Dart. There is an embankment 600 yards long, constructed by the Dartmouth Harbour Commissioners. A cottage hospital has been erected. Yacht and boat building are carried on; there is a large paint factory. The port is used as a coaling station for yachts and ocean steamers. Area, 1924 acres. Population (1881), 5725; (1901), 6037.

**Dartmouth,** a town in Halifax County, Nova Scotia, on the eastern side of Halifax harbour, connected with Halifax by a steam ferry. It contains four churches, large sugar refinery, foundries, machine shops, three saw mills, several factories, and a bank. Population, about 6500.

**Darwen,** a municipal borough in the Darwen parliamentary division of Lancashire, England, 4 miles south of Blackburn by rail. It is a centre of the cotton trade, and has also blast furnaces, and paper-making, paper-staining, and fire-clay works. New sewerage filtration works have been completed at a cost of £30,000. Recent erections are new buildings for the free library and a technical school. Area, 5952 acres. Population (1881), 29,744; (1891), 34,192; (1901), 38,311; of parliamentary division (1881), 61,092; (1891), 70,475; (1901), 78,793. The parish of Over-Darwen, which, together with various hamlets, and portions of Eccleshill and Lower Darwen, makes up the municipal borough, has an area of 5134 acres. Population (1881), 27,626; (1891), 31,680.

**Darwin, Charles Robert** (1809–1882), the famous English naturalist, author of the *Origin of Species*, was born at Shrewsbury on 12th February 1809. He was the younger of the two sons and the fourth child of Dr Robert Waring Darwin (1766–1848), a successful medical practitioner at Shrewsbury. His mother, a daughter of Josiah Wedgwood, died when Charles Darwin was eight years old. His grandfather was the great genius Dr Erasmus Darwin (1731–1802), who made suggestions upon the origin of species in many respects similar to those which were later more completely elaborated by Lamarck. Charles Darwin's elder brother, Erasmus Alvey (1804–1881), was interested in literature and art rather than science: on the subject of the wide difference between the brothers Charles wrote that he was "inclined to agree with Francis Galton in believing that education and environment produce only a small effect on the mind of anyone, and that most of our qualities are innate" (*Life and Letters*, London, 1887, p. 22). Darwin considered that his own success was chiefly due to "the love of science, unbounded patience in long reflecting over any subject, industry in observing and collecting facts, and a fair share of invention as well as of common sense" (*l.c.*, p. 107). He also says: "I have steadily endeavoured to keep my mind free so as to give up any hypothesis, however much beloved (and I cannot resist forming one on every subject), as soon as facts are shown to be opposed to it" (*l.c.*, p. 103). The essential causes of his success are to be found in this latter sentence, the creative genius ever inspired by existing knowledge to build hypotheses by whose aid further knowledge could be won, the calm unbiassed mind, the transparent honesty and love of truth which enabled him to abandon or to modify his own creations when they ceased to be supported by observation. The even balance between these powers was as important as their remarkable development. The great naturalist appeared in the ripeness of time, when the world was ready for his splendid generalizations. Indeed naturalists were already everywhere considering and discussing the problem of evolution, although Alfred Russel Wallace was the only one who, independently of Darwin, saw his way clearly to the solution. It is true that hypotheses essentially the same as natural selection were suggested much earlier by W. C. Wells (*Phil. Trans.*, 1813) and Patrick Matthew (*Naval Timber and Arboriculture*, 1831), but their views were lost sight of and produced no effect upon the great body of naturalists. In the preparation for Darwin Sir Charles Lyell's *Principles of Geology* played an important part, accustoming men's minds to the vast changes brought about by natural processes, and leading them, by its lucid and temperate discussion of Lamarck's and other views, to reflect upon evolution. Darwin's early education was conducted at Shrewsbury, first for a year at a day-school, then for seven years at Dr Butler's. He gained but little from the narrow system which was then universal. In 1825 he went to Edinburgh to prepare for the medical profession, for which he was unfitted by nature. After two sessions his father realized this, and in 1828 sent him to Cambridge with the idea that he should become a clergyman. He matriculated at Christ's College, and took his degree in 1831, tenth in the list of those who do not seek honours. Up to this time he had been keenly interested in sport, and in entomology, especially the collecting of beetles. Both at Edinburgh, where in 1826

he read his first scientific paper, and at Cambridge he gained the friendship of much older scientific men—Grant and Macgillivray at the former, Henslow and Sedgwick at the latter. He had two terms' residence to keep after passing his last examination, and studied geology with Sedgwick. Returning from their geological excursion together in North Wales (August 1831), he found a letter from Henslow urging him to apply for the position of naturalist on the *Beagle*, about to start on a surveying expedition. His father at first disliked the idea, but his uncle, Josiah Wedgwood, pleaded with success, and Darwin started on December 27, 1831, the voyage lasting until October 2, 1836. It is practically certain that he never left Great Britain after this latter date. After visiting the Cape de Verde and other Atlantic Oceanic islands, they surveyed on the South American coasts and adjacent islands (including the Galapagos), afterwards visiting Tahiti, New Zealand, Australia, Tasmania, Keeling Island, Maldives, Mauritius, St Helena, Ascension; and Brazil, de Verdes, and Azores on the way home. His work on the geology of the countries visited, and that on coral islands, became the subject of volumes which he published after his return, as well as his *Journal of a Naturalist*, and his other contributions to the official narrative. The voyage must be regarded as the real preparation for his life-work. His observations on the relation between animals in islands and those of the nearest continental areas, near akin and yet not the same, and between living animals and those most recently extinct and found fossil in the same country, here again related but not the same, led him even then to reflect deeply upon the modification of species. He had also been much impressed by "the manner in which closely allied animals replace one another in proceeding southwards" in South America. On his return home Darwin worked at his collections, first at Cambridge for three months and then in London. His pocket-book for 1837 contains the words: "In July opened first notebook on Transmutation of Species. Had been greatly struck from about the month of previous March [while still on the voyage and just over twenty-eight years old] on character of South American fossils, and species on Galapagos Archipelago. These facts (especially latter) origin of all my views." From 1838 to 1841 he was secretary of the Geological Society, and saw a great deal of Sir Charles Lyell, to whom he dedicated the second edition of his *Journal*. On January 29, 1839, he married his cousin, Emma Wedgwood, the daughter of Josiah Wedgwood of Maer. They lived in London until September 1842, when they moved to Down, which was Darwin's home for the rest of his life. His health broke down many times in London, and remained precarious during the whole of his life. The immense amount of work which he got through was only made possible by the loving care of his wife. For eight years (1846 to 1854) he was chiefly engaged upon four monographs on the recent and fossil Cirripede Crustacea (*Ray Soc.*, 1851 and 1854; *Palæontograph. Soc.*, 1851 and 1854). Towards the close of this work Darwin became very wearied of it, especially of the synonymy. For a time he hoped to start a movement which should discourage the habit of appending the name of the describer to the name of the species, a custom which he thought led to bad and superficial work. From this time he was engaged upon the numerous lines of inquiry which led to the great work of his life, the *Origin of Species*, published in November 1859.



CHARLES ROBERT DARWIN.
*(From a photograph by Elliott & Fry, London.)*

Soon after opening his note-book in July 1837, he began to collect facts bearing upon the formation of the breeds of domestic animals and plants, and quickly saw "that selection was the keystone of man's success. But how selection could be applied to organisms living in a state of nature remained for some time a mystery to me." Various ideas as to the causes of evolution occurred to him, only to be successively abandoned. He had the idea of "laws of change" which affected species and finally led to their extinction, to some extent analogous to the causes which bring about the development, maturity, and finally death of an individual. He also had the conception that species must give rise to other species or else die out, just as an individual dies unrepresented if it bears no offspring. These and other ideas, of which traces exist in his Diary, arose in his mind, together with perhaps some general conception of natural selection, during the fifteen months after the opening of his notebook. In October 1838 he read *Malthus on Population*, and his observations having long since convinced him of the struggle for existence, it at once struck him "that under these circumstances favourable variations would tend to be preserved, and unfavourable ones to be destroyed. The result of this would be the formation of new species. Here, then, I had a theory by which to work." In June 1842 he wrote out a sketch, which two years later he expanded to an essay occupying 231 pages folio. The idea of progressive divergence as an advantage in itself, because the competition is most severe between organisms most closely related, did not occur to him until long after he had come to Down. During the growth of the *Origin* Sir Joseph Hooker was his most intimate friend, and on January 11, 1844, he wrote: "at last gleams of light have come, and I am almost convinced (quite contrary to the opinion I started with) that species are not (it is like confessing a murder) immutable" (*l.c.*, ii. 23). In 1855 he began a correspondence with the great American botanist Asa Gray, and in 1857 explained his views in a letter which afterwards became classical. In 1856, urged by Lyell, he began the preparation of a third and far more expanded treatise, and had completed

about half of it when, on June 18, 1858, he received a manuscript essay from A. R. Wallace, who was then at Ternate in the Moluccas. Wallace wanted Darwin's opinion on the essay, which he asked should be forwarded to Lyell. Darwin was much startled to find in the essay a complete abstract of his own theory of natural selection. He forwarded it the same day, writing to Lyell, "your words have come true with a vengeance—that I should be forestalled." He placed himself in the hands of Lyell and Hooker, who decided to send Wallace's essay to the Linnean Society, together with an abstract of Darwin's work, which they asked him to prepare, the joint essay being accompanied by a preface in the form of an explanatory letter written by them to the secretary. The title of the joint communication was "On the Tendency of Species to form Varieties; and on the Perpetuation of Varieties and Species by Natural Means of Selection." It was read on July 1, 1858, and appears in the *Linn. Soc. Journal* (Zoology) for that year. In this statement of the Theory of Natural Selection, Darwin's part consisted of two sections, the first being extracts from his 1844 essay, including a brief account of sexual selection; the second consisting of an abstract of his letter to Asa Gray dated September 5, 1857. This latter, probably his first attempt to expound natural selection, cannot be surpassed as a clear statement of the theory. Darwin explained at the outset, what he insisted on elsewhere, that the facts of adaptation or contrivance in nature are the real difficulty to be explained by a theory of evolution, the stumbling-block of every previous suggestion. Until he could explain "the mistletoe, with its pollen carried by insects, and seed by birds—the woodpecker, with its feet and tail, beak and tongue, to climb the tree and secure insects"—he was "scientifically orthodox." Nevertheless he was led to believe in evolution, apart from any possible motive-cause, by "general facts in the affinities, embryology, rudimentary organs, geological history, and geographical distribution of organic beings." He then proceeds to describe the manner in which he met the difficulty of adaptation by "his notions on the means by which Nature makes her species." The essentials of the statement are as follows:—I. Man has made his domestic breeds of animals and plants by selection, conscious or unconscious, of very slight or greater variations. II. The material for selection exists in nature, namely, slight variations of all parts of the organism. III. The "unerring power" which sifts these variations is *Natural Selection* . . . which selects exclusively for the good of each organic being." The rate of increase is such that only a few in each generation can live: hence the never sufficiently appreciated struggle for life. "What a trifling difference must often determine which shall survive and which perish!" The remaining heads explain the complex nature of the struggle, the reasons for deficient direct evidence, the advantage of divergence, &c. In the Joint Essay the phrases "Natural Selection" and "Sexual Selection" were first made public by Darwin, the "struggle for existence" by Wallace. Darwin and Wallace had only met once before the departure of the latter for the East. Their rivalry in the discovery of the great principle of Natural Selection was the beginning of a lifelong friendship. Wallace was lying ill with intermittent fever at Ternate in February 1858, when he began to think of Malthus's Essay, read several years before: suddenly the idea of the survival of the fittest flashed upon him. In two hours he had "thought out almost the whole of the theory," and in three evenings had finished his essay. Darwin, also inspired after reading Malthus, in October 1838, did not publish until nearly twenty years had elapsed, and then only when Wallace sent him his essay. Canon Tristram was the first to apply the new theory, explaining by its aid the colours of desert birds, &c. (*Ibis*, October 1859).

Acting under the advice of Lyell and Hooker, Darwin then began to prepare what was to become the great work of his life. It appeared November 24, 1859, with the full title, *On the Origin of Species by Means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life*. The whole edition of 1250 copies was exhausted on the day of issue. The first four chapters explain the operation of artificial selection by man and of natural selection in consequence of the struggle for existence. The fifth chapter deals with the laws of variation and causes of modification other than natural selection. The five succeeding chapters consider difficulties in the way of a belief in evolution generally as well as in natural selection. The three remaining chapters (omitting the recapitulation which occupies the last) deal with the evidence for evolution. The theory which suggested a cause of evolution is thus given the foremost place, and the evidence for the existence of evolution considered last of all. This method of presentation was no doubt adopted because it was just the want of a reasonable motive-cause which more than anything else prevented the acceptance of evolution. But the other side of the book must not be eclipsed by the brilliant theory of Darwin and Wallace. The evidence for evolution itself had never before been thought out and marshalled in a manner which bears any comparison with that of Darwin in the *Origin*, and the work would have been in the highest degree epoch-making had it consisted of the later chapters alone. In the fifth chapter Darwin incorporated a certain proportion of the doctrines of Buffon,—modifications due to the direct influence of environment; and of Lamarck,—the hereditary effects of use and disuse. Lyell for a long time hesitated to accept the new teaching, and Darwin carried on a long correspondence with him. His public confession of faith was made at the Anniversary Dinner of the Royal Society in 1864. A storm of controversy arose over the book, reaching its height at the meeting of the British Association at Oxford in 1860, when the celebrated duel between Huxley and the Bishop of Oxford took place. Throughout these struggles Huxley was the foremost champion for evolution and for fair play to natural selection, although he never entirely accepted the latter theory, holding that until man by his selection had made his domestic breed sterile *inter se*, there was no sufficient evidence that selection accounts for natural species which are thus separated by the barrier of sterility. The theory of natural selection was at first greatly misunderstood. Thus some writers thought it implied conscious choice in the animals themselves, others that it was the personification of some active power. By many it was thought to be practically the same idea as Lamarck's. Herbert Spencer's alternative phrase, "the survival of the fittest," probably helped to spread a clear appreciation of Darwin's meaning.

The history of opinion since 1859 may be summed up as follows. Evolution soon gained general acceptance, except among a certain number of those of middle or more advanced age at the time when the *Origin* appeared. Although natural selection had been an essential force in producing this conviction, there gradually grew up a tendency to minimize its importance in relation to the causes originally suggested by Buffon and Lamarck, which were ably presented and further elaborated by Herbert Spencer. In America a school of Neo-Lamarckians appeared, and for a time flourished under the inspiration of the vigorous personality of E. D. Cope. The writings of August Weismann next raised a controversy over the scope of heredity, assailing the very foundation of the hypotheses of Buffon, Lamarck, and Herbert Spencer by demanding

evidence that the "acquired characters" upon which they rest are capable of hereditary transmission. The quantitative determination of heredity has been the subject of much patient investigation under the leadership of Francis Galton. The question of isolation as a factor in species-formation has been greatly discussed, G. J. Romanes proposing, in his hypothesis of "Physiological Selection," that the barrier of sterility may arise spontaneously by variation between two sets of individuals as the beginning instead of the climax of specific distinction. Others have fixed their attention upon the variations, which provided the material for natural selection, and have advocated the view that evolution proceeds by immense strides instead of the minute steps in which Darwin and Wallace believed. Others, again, have found significance in the artificial production of "monstrosities" or huge modifications during individual development. All through the period a varying proportion of naturalists, probably larger now than at any other time, has followed the founders of the theory, and has sought the motive-cause of evolution in "the accumulative power of natural selection," which Darwin, as his first public statement indicates, looked upon "as by far the most important element in the production of new forms." They hold, with Darwin and Wallace, that although variation provides the essential material, natural selection, from its accumulative power, is of such paramount importance that it may be said to create new species as truly as a man may be said to make a building out of the material provided by stones of various shapes, a metaphor suggested and elaborated by Darwin, and forming the concluding sentences of *The Variation of Animals and Plants under Domestication.* This, probably the second in importance of all his works, was published in 1868, and may be looked upon as a complete account of the material of which he had given a very condensed abstract in the first chapter of the *Origin*, together with the conclusions suggested by it. He finally brought together an immense number of apparently disconnected sets of observations under his "provisional hypothesis of pangenesis," which assumes that every cell in the body, at every stage of growth and in maturity, is represented in each germ-cell by a gemmule. The germ-cell is only the meeting-place of gemmules, and the true reproductive power lies in the whole of the body-cells which despatch their representatives, hence "pangenesis." There are reasons for believing that this infinitely complex conception, in which, as his letters show, he had great confidence, was forced upon Darwin in order to explain the hereditary transmission of acquired characters involved in the small proportion of Lamarckian doctrine which he incorporated. If such transmission does not occur, a far simpler hypothesis based on the lines of Weismann's "continuity of the germ-plasm" is sufficient to account for the facts.

The *Descent of Man, and Selection in Relation to Sex*, was published in 1871; as the title implies, it really consists of two distinct works. The first, and by far the shorter, was the full justification of his statement in the *Origin* that "light would be thrown on the origin of man and his history." In the second part he brought together a large mass of evidence in support of his hypothesis of sexual selection which he had briefly described in the 1858 essay. This hypothesis explains the development of colours and structures peculiar to one sex and displayed by it in courtship, by the preferences of the other sex. The majority of naturalists probably agree with Darwin in believing that the explanation is real, but relatively unimportant. It is interesting to note that only in this subject and those treated of in the *Variation under Domestication* had Darwin exhausted the whole of the material which he had collected. The *Expression of the Emotions*, published in 1872, offered a natural explanation of phenomena which appeared to be a difficulty in the way of the acceptance of evolution. In 1876 Darwin brought out his two previously published geological works on *Volcanic Islands* and *South America* as a single volume. The widely read *Formation of Vegetable Mould through the Action of Worms* appeared in 1881. He also published the following volumes on Botanical subjects. The *Fertilization of Orchids* appeared in 1862. The subject of cross-fertilization of flowers was in Darwin's mind, as shown by his notebook in 1837. In 1841 Robert Brown directed his attention to Sprengel's work (Berlin, 1793), which confirmed his determination to pursue this line of research. *The Effects of Cross- and Self-Fertilization in the Vegetable Kingdom* (1876) contained the direct evidence that the offspring of cross-fertilized individuals are more vigorous, as well as more numerous, than those produced by a self-fertilized parent. *Different Forms of Flowers on Plants of the Same Species* appeared in 1877. It is here shown that the different forms, although each possesses both kinds of sexual organs, is specially adapted to be fertilized by the pollen of another form, and that when artificially fertilized by its own pollen less vigorous offspring, bearing some resemblance to hybrids, are produced. He says, "no little discovery of mine ever gave me so much pleasure as the making out the meaning of heterostyled flowers" (*Autobiography*). *Climbing Plants* was published in 1875, although it had, in large part, been communicated to the Linnean Society, in whose publications much of the material of several of his other works appeared. This inquiry into the nature of the movements of twining plants was suggested to him in a paper by Asa Gray. *The Power of Movement in Plants* (1880) was produced by him in conjunction with his son Francis. It was an inquiry into the minute power of movement possessed, he believed, by plants generally, out of which the larger movements of climbing plants of many different groups had been evolved. The work included an investigation of other kinds of plant movement due to light, gravity, &c., all of which he regarded as modifications of the one fundamental movement (circumnutation), which exists in a highly specialized form in climbing plants. *Insectivorous Plants* (1875) is principally concerned with the description of experiments on the Sun-dew (*Drosera*), although other insect-catching plants, such as *Dionæa*, are also investigated.

Charles Darwin's long life of patient, continuous work, the most fruitful, the most inspiring, in the annals of modern science, came to an end on April 19, 1882. He was buried in Westminster Abbey on April 26. It is of much interest to attempt to set forth some of the main characteristics of the man who did so much for modern science, and in so large a measure moulded the form of modern thought. Although his ill-health prevented Darwin, except on rare occasions, from attending scientific and social meetings, and thus from meeting and knowing the great body of scientific and intellectual workers of his time, probably no man has ever inspired a wider and deeper personal interest and affection. This was in part due to the intimate personal friends who represented him in the circles he was unable frequently to enter, but chiefly to the kindly, generous, and courteous nature which was revealed in his large correspondence and published writings, and especially in his treatment of opponents.

In a deeply interesting chapter of the *Life and Letters* Francis Darwin has given us his reminiscences of his father's everyday life. Rising early, he took a short walk before breakfasting alone at 7.45, and then at once set to work, "considering the 1½ hours between 8.0 and 9.30 one of his best working times." He then read his letters and listened to reading aloud, returning to work at about

10.30. At 12 or 12.15 "he considered his day's work over," and went for a walk, whether wet or fine. For a time he rode, but after accidents had occurred twice, was advised to give it up. After lunch he read the newspaper and wrote his letters or the MS. of his books. At about 3.0 he rested and smoked for an hour while being read to, often going to sleep. He then went for a short walk, and returning about 4.30, worked for an hour. After this he rested and smoked, and listened to reading until tea at 7.30, a meal which he came to prefer to late dinner. He then played two games of backgammon, read to himself, and listened to music and to reading aloud. He went to bed, generally very much tired, at 10.30, and was often much troubled by wakefulness and the activity of his thoughts.

It is thus apparent that the number of hours devoted to work in each day was comparatively few. The immense amount he achieved was due to concentration during these hours, also to the unfailing and, because of his health, the necessary regularity of his life.

The appearance of Charles Darwin has been made well known in numerous portraits and statues. He was tall and thin, being about 6 feet high, but looked less because of a stoop, which increased towards the end of his life. As a young man he had been active, with considerable powers of endurance, and possessed in a marked degree those qualities of eye and hand which make the successful sportsman.

Charles Darwin was, as a young man, a believer in Christianity, and was sent to Cambridge with the idea that he would take Holy Orders. It is probable, however, that he had merely yielded to the influences of his home, without thinking much on the subject of religion. He first began to reflect deeply on the subject during the two years and a quarter which intervened between his return from the *Beagle* (October 2, 1836) and his marriage (January 29, 1839). His own words are, "disbelief crept over me at a very slow rate, but was at last complete. The rate was so slow that I felt no distress."

His attitude was that of the tolerant unaggressive agnostic, sympathizing with and helping in the social and charitable influences of the English Church in his parish. He was evidently most unwilling that his opinions on religious matters should influence others, holding, as his son, Francis Darwin, says, "that a man ought not to publish on a subject to which he has not given special and continuous thought" (*l.c.*, i. p. 305).

In addition to the personal qualities and powers of Charles Darwin, there were other contributing causes without which the world could never have reaped the benefit of his genius. It is evident that Darwin's health could barely have endured the strain of working for a living, and that nothing would have been left over for his researches. A deep debt of gratitude is owing to his father, Dr Darwin, who placed him in a position in which all his energy could be devoted to scientific work and thought. But his ill-health was such that this important and essential condition would have been insufficient without another even more essential. Francis Darwin, in the *Life and Letters* (i. pp. 159–160), writes these eloquent and pathetic words:—"No one indeed, except my mother, knows the full amount of suffering he endured, or the full amount of his wonderful patience. For all the latter years of his life she never left him for a night; and her days were so planned that all his resting hours might be shared with her. She shielded him from every avoidable annoyance, and omitted nothing that might save him trouble, or prevent him becoming over-tired, or that might alleviate the many discomforts of his ill-health. I hesitate to speak thus freely of a thing so sacred as the lifelong devotion which prompted all this constant and tender care. But it is, I repeat, a principal feature of his life, that for nearly forty years he never knew one day of the health of ordinary men, and that thus his life was one long struggle against the weariness and the strain of sickness. And this cannot be told without speaking of the one condition which enabled him to bear the strain and fight out the struggle to the end."

Charles Darwin was honoured by the chief societies of the civilized world. He was made a Knight of the Prussian Order, "Pour le Mérite" in 1867, a Corresponding Member of the Berlin Academy of Sciences in 1863, a Fellow in 1878, and later in the same year a Corresponding Member of the French Institute in the Botanical Section. He received the Bressa Prize of the Royal Academy of Turin, and the Baly Medal of the Royal College of Physicians in 1879, the Wollaston Medal of the Geological Society in 1859, a Royal Medal of the Royal Society in 1853, and the Copley Medal in 1864. His health prevented him from accepting the Honorary Degree which Oxford University wished to confer on him, but his own University had stronger claims, and he became an Honorary LL.D. Cantab. in 1877.

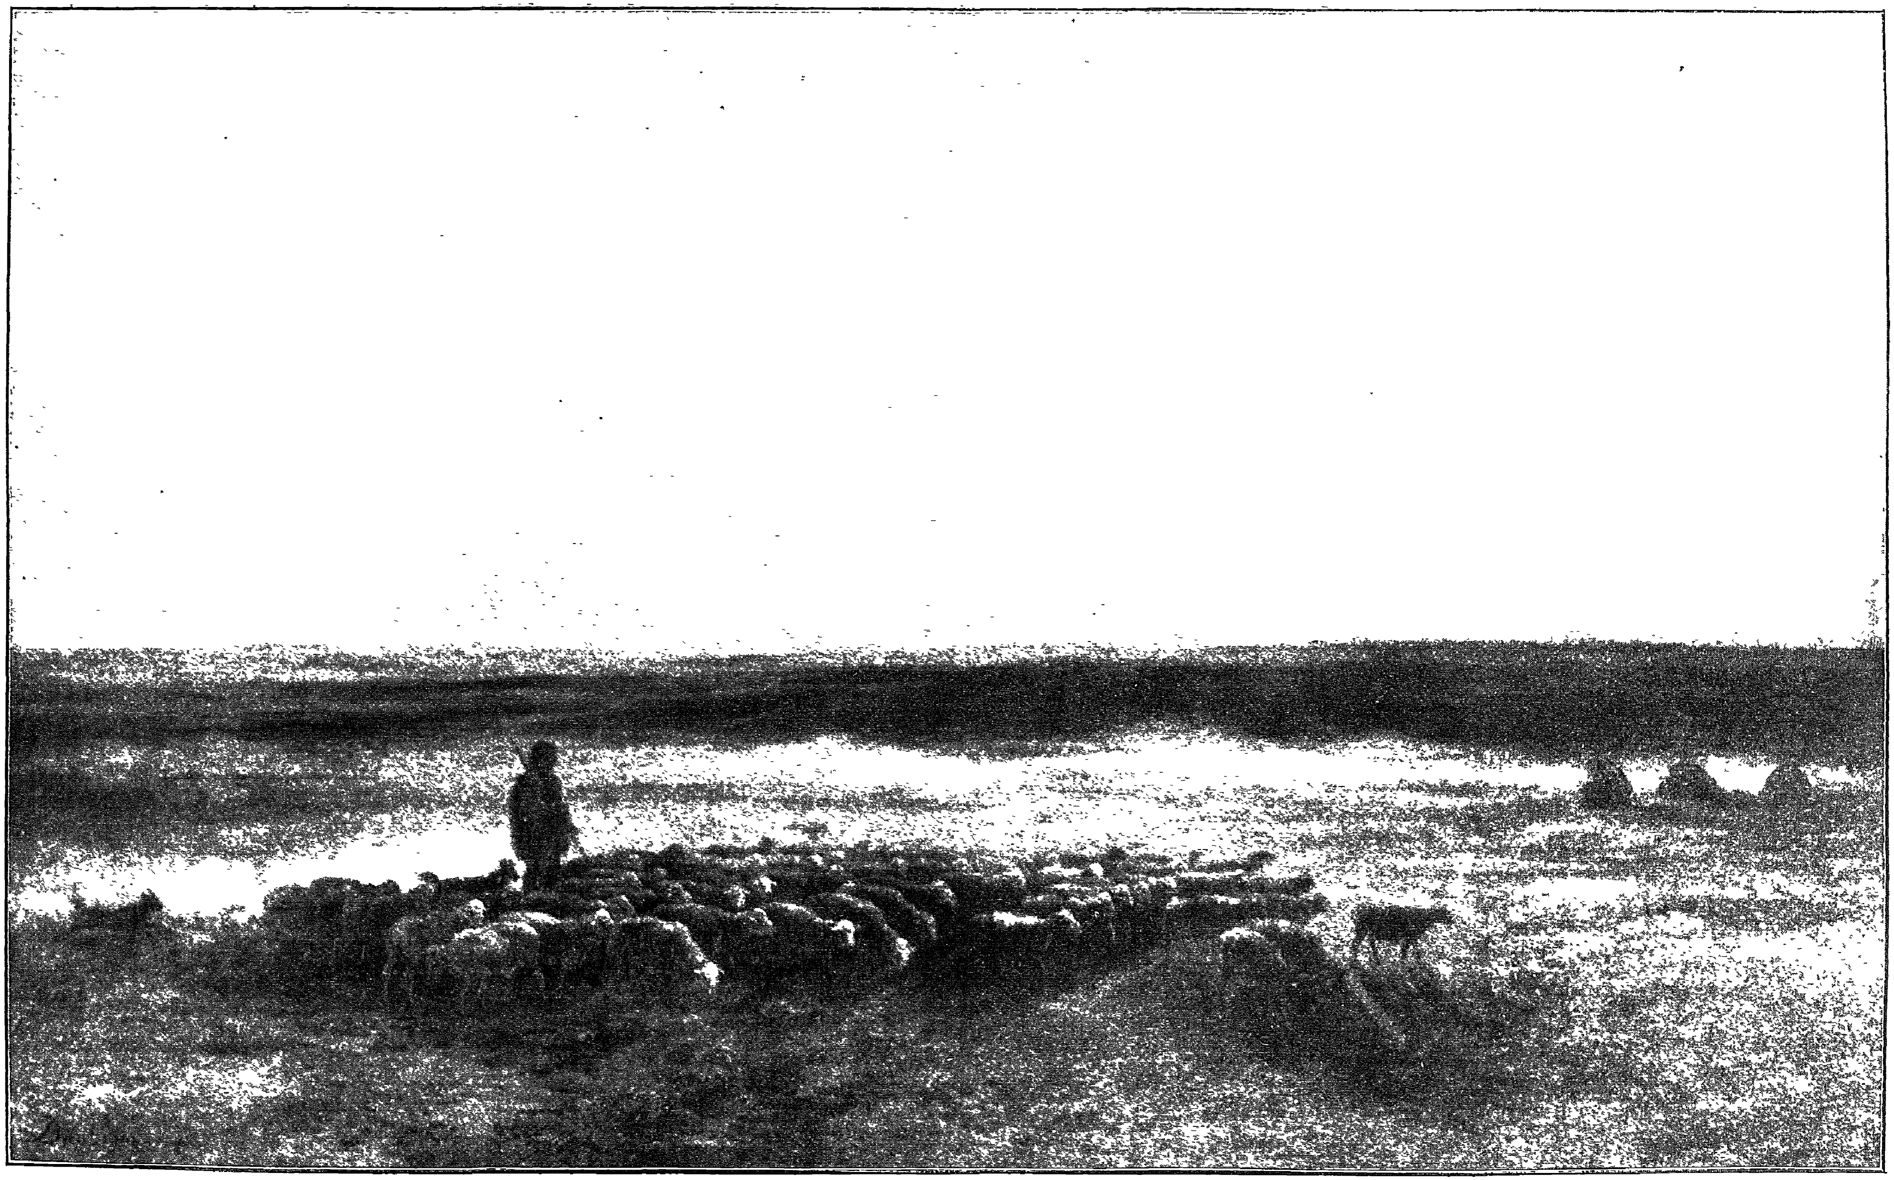
**Datia,** a native state of India, in the Bundelkhand agency. It lies in the extreme north-west of Bundelkhand, near Gwalior. Area, 837 square miles. Population, (1881), 182,598; (1891), 186,440, showing an increase of 2 per cent.; average density, 223 persons per square mile. Estimated gross revenue, Rs.10,00,000; tribute to Sindhia paid through the British Government, Rs.15,000. The chief, whose title is Maharaja, is a Rajput of the Bundela clan, being descended from a younger son of a former chief of Orchha. The present Maharaja was appointed K.C.S.I. in 1898. The state suffered from famine in 1896–97, and again to a less extent in 1899–1900. It is traversed by the branch of the Indian Midland Railway from Jhansi to Gwalior. The TOWN of DATIA is situated in 25° 40′ N. lat. and 78° 30′ E. long.; railway station, 16 miles from Jhansi. Population (1881), 28,346; (1891), 27,566. It is surrounded by a stone wall, enclosing handsome palaces, with gardens.

**Daubigny, Charles-François** (1817–1878), French landscape painter, allied in several ways with the Barbizon School. He was born in Paris, 15th February 1817, but spent much time as a child at Valmondois, a village on the Oise to the north-west of Paris. Daubigny was the son of an artist, and most of his family were painters. He began to paint very early in life, and at the age of seventeen he took a studio of his own. Within twelve months he had saved enough to go to Italy, where he studied and painted for nearly two years; he then returned to Paris, not to leave it again until, in 1860, he took a house at Auvers on the Oise. By 1837 Daubigny had become famous as a river and landscape painter, although he had been devoting himself as well to drawing in black-and-white, to etching, wood engraving, and lithography. In 1855 his picture, "Lock at Optevoz," now in the Louvre, was purchased by the State; four years later Daubigny was created Knight of the Legion of Honour, and in 1874 he was promoted to be an Officer. In 1866, at the invitation of Lord, then Mr, Leighton and others, he visited London, where, however, he was hurt by



"MOONLIGHT." BY C. F. DAUBIGNY.

*(From the Picture in the possession of the Hon. George A. Drummond, Montreal, Canada.)*

his now famous "Moonlight" being badly hung in the Old Royal Academy. But the personal encouragement of his admirers in England made up for the disappointment, and the sale of his picture to a Royal Academician greatly pleased him. In 1870–71 he again visited London, and subsequently Holland, where he painted a number of river scenes with windmills. In 1874, having returned to Paris, he fell ill, and from that time until he died (on 19th February 1878) his work won less distinction than before. Daubigny's finest pictures were painted between 1864 and 1874, and these for the most part consist of carefully completed landscapes with trees, river, and a few ducks. It has curiously been said, yet with some appearance of truth, that when Daubigny liked his pictures himself he added another duck or two, so that the number of ducks often indicates greater or less artistic quality in his pictures. One of his sayings was, "The best pictures do not sell," as he frequently found his finest achievements little understood. Yet although during the latter part of his life he was considered a highly successful painter, the money value of his pictures since his death has increased nearly tenfold. Daubigny is chiefly preferred in his riverside pictures, of which he painted a great number, but although there are two large landscapes by Daubigny in the Louvre, neither is a river view. They are for that reason not so typical as many of his smaller Oise and Seine pictures. None of his paintings can be seen in public galleries in Great Britain, although they frequently appear in loan exhibitions both in London and in Scotland.

The works of Daubigny are, like Corot's, to be found in many modern collections. His most ambitious canvases are: "Spring-time" (1857), in the Louvre; "Borde de la Cure, Morvan" (1864); "Villerville sur Mer" (1864); "Moonlight" (1865); "Andrésy sur Oise" (1868); and "Return of the Flock—Moonlight" (1878).

His followers and pupils were his son Karl (who sometimes painted so well that his works are occasionally mistaken for those of his father, though in few cases do they equal his father's mastery), Oudinot, Delpy, and Damoye.

**Daudet, Alphonse** (1840–1897), French novelist, was born at Nîmes on the 13th May 1840. His family, on both sides, belonged to the *bourgeoisie*. The father, Vincent Daudet, was a silk manufacturer—a man dogged through life by misfortune and failure. The lad, amid much truancy, had but a depressing boyhood. In 1856 he left Lyons, where his schooldays had been mainly spent, and began life as an usher at Alais, in the south. The position proved to be intolerable. As Dickens declared that all through his prosperous career he was haunted in dreams by the miseries of his apprenticeship to the blacking business, so Daudet says that for months after leaving Alais he would wake with horror thinking he was still among his unruly pupils. On the 1st November 1857 he abandoned teaching, and took refuge with his brother Ernest, only some three years his senior, who was trying, "and thereto soberly," to make a living as a journalist in Paris. Alphonse betook himself to his pen likewise,—wrote poems, shortly collected into a small volume *Les Amoureuses* (1858), which met with a fair reception,—obtained employment on the *Figaro*, then under Villemessent's energetic editorship, wrote two or three plays, and began to be recognized, among those interested in literature, as possessing individuality and promise. Morny, the emperor's all-powerful minister, appointed him to be one of his secretaries,—a post which he held till Morny's death in 1865,—and showed him no small kindness. He had put his foot on the road to fortune. The first of his longer books, *Le Petit Chose* (1868), did not, however, produce any very popular sensation. It is, in its main feature, the story of his own earlier years told with much grace and pathos. But the next book, *Froment jeune et Risler aîné* (1874), at once took the world by storm. It struck a note, not new certainly in English literature, but comparatively new in French. Here was a writer who possessed the gift of laughter and tears, a writer not only sensible to pathos and sorrow, but also to moral beauty. He could create too. His characters were real and also typical; the *ratés*, the men who in life's battle had flashed in the pan, were touched with a master hand. The book was alive. It gave the illusion of a real world. *Jack*, the story of an illegitimate child, a martyr to his mother's selfishness, which followed in 1876, served only to deepen the same impression. Henceforward his career was that of a very successful man of letters,—publishing novel on novel, *Le Nabab* (1877), *Les Rois en Exil* (1879), *Numa Roumestan* (1880), *Sapho*, *L'Immortel*,—and writing for the stage at frequent intervals,—giving to the world his reminiscences in *Trente ans de Paris* and *Souvenirs d'un homme de lettres*. These, with the three *Tartarins*,—Tartarin the mighty hunter, Tartarin the mountaineer, Tartarin the colonist,—and the admirable short stories, written for the most part before he had acquired fame and fortune, constitute his life work. Though Daudet defended himself from the charge of imitating Dickens, it is difficult altogether to believe that so many similarities of spirit and manner were quite unsought. What, however, was purely his own was his style. It is a style that may rightly be called "*impressionist*," full of light and colour, not descriptive after the old fashion, but by a masterly juxtaposition of words that are like pigments flashing its intended effect. Nor does it convey, like the style of the Goncourts, for example, a constant feeling of effort. It is full of felicity and charm,—*un charmeur* M. Zola has called him. An intimate friend of Edmond de Goncourt (who died in his house), of Flaubert, of M. Zola, Daudet belonged essentially to the naturalist school of fiction. His own experiences, his surroundings, the men with whom he had been brought into contact, various persons who had played a part, more or less public, in Paris life—all passed into his art. But he vivified the material supplied by his memory. His world has the great gift of life. *L'Immortel* is a bitter attack on the French Academy, to which august body Daudet never belonged. His married life—he married in 1867—seems to have been singularly happy. There was perfect intellectual harmony, and Madame Daudet possesses much of his literary gift. In his later years came insomnia, failure of health, and chloral. He died in Paris on the 17th December 1897. The story of Daudet's earlier years is told in his brother Ernest Daudet's *Mon frère et moi*. There is a good deal of autobiographical detail in Daudet's *Trente ans de Paris* and *Souvenirs d'un homme de lettres*, and also scattered in his other books. The references to him in the *Journal des Goncourts* are numerous. (F. T. M.)

**Dauphiné**, one of the old provinces (the name is still in current use in the country) of pre-Revolutionary France, in the south-east portion of France, between Provence and Savoy. After the death of the last king of Burgundy, Rudolf III., in 1032, Dauphiné (as part of his realm) reverted to the far-distant emperor. Much confusion fol-

lowed, out of which the counts of Albon (between Valence and Vienne) gradually came to the front. The first dynasty ended in 1162 with Guigue V., whose daughter and heiress, Beatrice, carried the possessions of her house to her husband, Hugh III., duke of Burgundy. Their son, André, continued the race, this second dynasty making many territorial acquisitions, among them (by marriage) the Embrunais and the Gapençais in 1232. In 1282 the second dynasty ended in another heiress, Anna, who carried all to her husband, Humbert, lord of La Tour du Pin (between Lyons and Grenoble). The title of the chief of the house was Count (later Dauphin) of the Viennois, *not* of Dauphiné.

The origin of the title "Dauphin" (borne also by the allied house of Auvergne) is very obscure. Guigue IV. (1132–1142) seems to have adopted the rare name "Delphinus" as a second Christian name, and so did his son, Guigue V. (1142–1162). The latter's daughter, Beatrice, the heiress, gave it to her son André, to recall his descent from the ancient house of the counts of Albon. Two princes of the second dynasty, namely, Guigue VI. and John I., use the form "Dalphini" (genitive case) as a sort of patronymic. But even under Guigue VI. (1237–1270) the term "Delphinus" is used (especially by foreigners) as a title of dignity, and is so borne regularly by the third dynasty. The "canting arms" of a dolphin were borrowed from the Counts of Clermont (Dauphins of Auvergne), and appear first in 1237 on a seal of Guigue VI., son of André Dauphin (1192–1237). Humbert II. (1333–1349), grandson of the heiress Anna, was the last independent Dauphin, selling his dominions in 1349 to Charles of Valois, and stipulating that every one who inherited this province should bear the name of Dauphin, and quarter the arms of Dauphiné with those of France. As a matter of fact, the title was borne by all succeeding eldest sons of the kings of France. In 1422 the Diois and the Valentinois by the will of the last count passed to the eldest son of Charles VI., and in 1424 were annexed to the Dauphiné. Louis (1440–1461), later Louis XI. of France, was the last Dauphin who occupied a semi-independent position. The suzerainty of the emperor gradually died out. In the 16th century the names of Farel and of the duke of Lesdiguières are prominent in Dauphiné history. The "States" of Dauphiné (dating from about the middle of the 14th century) were suspended by Louis XIII. in 1630. (W. A. B. C.)

**Davenport,** capital of Scott county, Iowa, U.S.A., in 41° 30′ N. lat. and 90° 39′ W. long., on the west bank of the Mississippi, at the foot of Rock Island Rapids, at an altitude on the river bank of 590 feet. It is laid out on a regular plan, is supplied with water from the Mississippi by the Holly pumping system, is well sewered and well paved with brick and macadam, and contains six wards. It is entered by three great railway systems, and enjoys a large trade. In 1890 it contained 475 manufacturing establishments, with a capital of $8,732,122, and employing 5136 hands; the value of the manufactured goods was $10,357,232. The principal articles of manufacture were lumber and flour. The assessed valuation of real and personal property in 1900, on a basis of about one-half of the full value, was $14,396,585, the debt of the municipality was $441,112, and the total rate of taxation was $51·75 per $1000. The death-rate in 1900 was 15·9. Population (1880), 21,831; (1890), 26,872; (1900), 35,254, of whom 8479 were foreign born and 488 negroes.

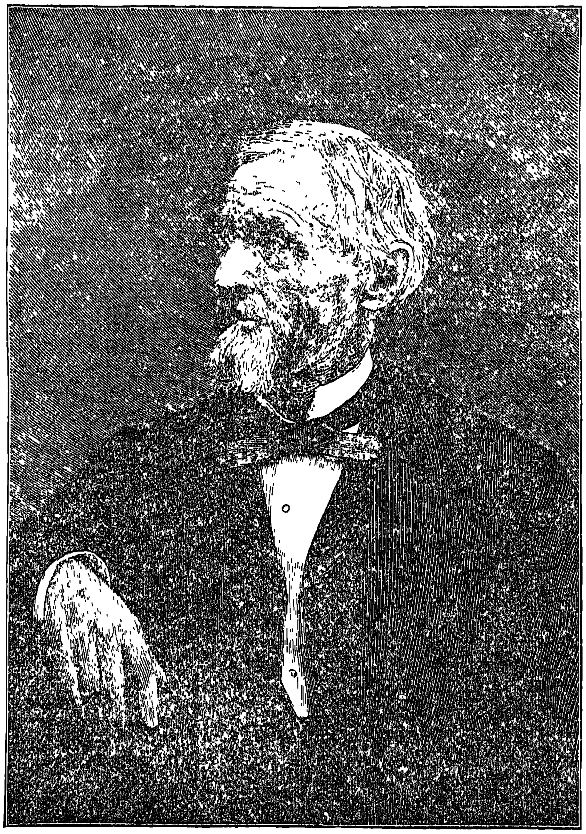
**Daventry,** a municipal borough of Northamptonshire, England, 12 miles west by north of Northampton. There are Established, Roman Catholic, Congregational, and Methodist churches; an endowed grammar school, and a grammar school for girls. A public recreation ground was opened in 1890. The principal industry is the manufacture of boots and shoes. Area, 3427 acres. Population (1881), 3859; (1901), 3780.

**Davey of Fernhurst, Horace Davey,** Baron (1833——), English judge, son of Peter Davey, of Horton, Bucks, was born 30th August 1833, and educated at Rugby and University College, Oxford. He took a double first-class in classics and mathematics, was senior mathematical scholar and Eldon law scholar, and was elected a fellow of his college. In 1861 he was called to the Bar at Lincoln's Inn, and read in the chambers of Mr (afterwards Vice-Chancellor) Wickens. Devoting himself to the Chancery side, he soon acquired a large practice, and in 1875 became a Q.C. In 1880 he was returned to Parliament as a Liberal for Christchurch, Hants, but lost his seat in 1885. On Mr Gladstone's return to power in 1886 he was appointed Solicitor-General and was knighted, but had no seat in the House; from 1888 to 1892 he sat for Stockton-on-Tees. As an equity lawyer Sir Horace Davey ranks among the finest intellects and the most subtle pleaders ever known at the English Bar. He was standing counsel to the University of Oxford, and senior counsel to the Charity Commissioners, and was engaged in all the important Chancery suits of his time. Among the chief leading cases in which he took a prominent part were those of The Mogul Steamship Company, Boswell *v.* Cokes, Erlanger *v.* New Phosphate Co., and the Ooregum Gold Mines Co.; he was counsel for the promoters in the trial of the Bishop of Lincoln, and leading counsel in the Berkeley Peerage case. In 1862 he married Miss Louisa Donkin. In 1893 he was raised to the Bench as a Lord Justice of Appeal, and in the next year was made a Lord of Appeal in Ordinary and a life-peer.

**David, Félicien** (1810–1876), French composer, was born on 13th April 1810 at Cadenet. After having studied for a while at the Paris Conservatoire, he joined the sect of Saint Simonians, and travelled in the East in order to preach the new doctrine. After three years' absence, during which he visited Constantinople, Smyrna, and spent some time in Egypt, he returned to France and published a collection of Oriental melodies. For several years he worked in retirement, and wrote two symphonies, some chamber music, and songs. On the 8th of December 1844 he suddenly leapt into fame through the extraordinary success obtained by his symphonic ode entitled *Le Désert*, produced at the Conservatoire. In this work David had struck out a new line. He had attempted in simple strains to evoke the majestic stillness of the desert. Notwithstanding its title of "symphonic ode," *Le Désert* has little in common with the symphonic style. What distinguishes it is a certain *naïveté* of expression and an effective Oriental colouring. In this last respect David may be looked upon as the precursor of a whole army of composers. His succeeding works, *Moïse au Sinaï* (1846), *Christophe Colomb* (1847), *L'Eden* (1848), scarcely bore out the promise shown in *Le Désert*, although the second of these compositions was successful at the time of its production. David now turned his attention to the theatre, and produced the following operas in succession: *La Perle du Brésil* (1851), *Herculanum* (1859), *Lalla-Roukh* (1862), *Le Saphir* (1865). Of these, *Lalla-Roukh* is the one which has obtained the greatest success. It is still played in France. He died at Saint-Germain-en-Laye on the 29th of August 1876. If David can scarcely be placed in the first rank of French composers, he nevertheless deserves the consideration due to a sincere artist, one who was undoubtedly inspired by lofty ideals. At a time when the works of Berlioz were caviare to the general, David succeeded in making the public take interest in music of a picturesque and descriptive kind. Thus he may be considered as one of the pioneers of modern French musical art. (A. He.)

**Davis, Jefferson** (1808–1889), American soldier and statesman, President of the Confederate States in the American War of Secession, was born on 3rd June 1808 in Christian (now Todd) county, Kentucky. His father, Samuel Davis, was of Welsh, his mother, Jane Cook, of Scotch-Irish, descent. Jefferson Davis was edu-

cated at Transylvania College and West Point Academy. From the latter he graduated in July 1828, with the rank of second lieutenant of infantry. He was assigned for duty to Jefferson Barracks at St Louis, and later to Fort Crawford, now Prairie du Chien, Wisconsin. Here he met Sarah Knox, the daughter of the commanding officer, whom he married two years later. During the Black Hawk war he was under General Winfield Scott at Fort Snelling, and was sent to Dixon, Illinois, to muster into service some volunteers from that State. Their captain was Abraham Lincoln, and Lieutenant Davis is said to have administered to him his first oath of allegiance. After his marriage, he resigned from the army and settled in Mississippi, where Mrs Davis died of fever, and Jefferson Davis afterwards married Miss Varina Howell of Mississippi. In 1843 Mr Davis entered the field of politics as a Democrat, and exhibited great power as a public speaker. In 1844 he was chosen as Presidential Elector, and in 1845 was elected to Congress. From the beginning of his political career he advocated a strict construction of the United States Constitution. He was an ardent admirer of John C. Calhoun and his political opinions. In his speeches in Congress, which were few, he clearly defined his position in regard to State Rights, which he consistently held ever afterwards. During his first session, war with Mexico was declared, and he left his seat to take command of the First Regiment of Mississippi Volunteers. He was greatly distinguished for gallantry and soldierly conduct at Monterey and Buena Vista. In this last battle he was severely wounded early in the engagement, but continued in command until victory crowned the American arms.



JEFFERSON DAVIS.
*(From a photograph by Sarony, New York.)*

Upon his return to his home, he was made a United States Senator. After a service of nearly six years, he resigned his seat to accept the nomination for Governor of his State, but was defeated. In 1853 he accepted the position of Secretary of War in the Cabinet of President Pierce, and for four years performed the duties of the office with great distinction and with lasting benefit to the nation. He organized the engineer companies which explored and reported on the several proposed routes for a railway connecting the Mississippi Valley with the Pacific Ocean. He effected the enlargement of the army, and made material changes in its equipment of arms and ammunition, utilizing the latest improvements. He made his appointments of subordinates on their merits, regardless of party considerations. He revised the system of tactics, perfected the signal corps service, and enlarged the coast and frontier defences of the country. At the end of his service in the Cabinet, he was returned to the Senate, and continued as a member until the secession of his State in 1861. As a senator he stood in the front rank in a body distinguished for its ability; and his purity of character and courteous manner, together with his intellectual gifts, won him the esteem of all parties. While believing in Secession as a last resort, he earnestly sought to avoid the necessity, and when his State passed the ordinance he resigned his seat with the saddest forebodings of the impending conflict. His parting speech was a clear and able statement of the position taken by his State, and a most pathetic expression of his feelings in saying farewell to his associates.

On 25th January 1861 Mr Davis was commissioned Major-General of the forces Mississippi was raising in view of the threatened conflict. On the 9th of February he received the unanimous vote of the Congress of the seceded States as President of the "Confederate States of America." This office he had not sought, preferring service in the field. His brilliant career, both as a civilian and a soldier, drew all eyes to him as best fitted to guide the fortunes of the new Confederacy, and with a deep sense of the responsibility he obeyed the call. He heartily approved of the "Peace Conference," which attempted to draw up a plan of reconciliation between the two sections, but whose failure made war inevitable. The disparity between the hostile sections was very great. In white population the North had four times that of the South, and her manufacturing resources were nearly five hundred times as great; she had uninterrupted commerce with the outside world, and out of her population and the great stream of immigrants she had an unlimited supply of soldiery. She had the army and navy, with the munitions of war belonging to the Federal Government. On the other hand, the South had to create everything needed for war. Never having been a manufacturing people, and having her ports soon blockaded, she was greatly at a disadvantage. It was, indeed, astonishing that she was able to maintain the unequal contest for four years. Montgomery, Alabama, was the first Confederate capital, but after Virginia joined her sister States, the seat of government was removed to Richmond. How Mr Davis—of whom Mr Gladstone, in the early days of English sympathy with the South, said that he had "made a nation"—bore himself in his most responsible position during the gigantic conflict which ensued, cannot here be related in detail. It is sufficient to say that it was with great ability and an unblemished character. In a wonderfully short time he organized and put into the field one of the finest bodies of soldiers of which history has record. Factories sprung up in the South in a few months, supplying the army with arms and munitions of war, and the energy of the President was everywhere apparent. That he committed serious errors, his warmest admirers will hardly deny. Unfortunately his firmness developed into obstinacy, and exhibited itself in continued confidence in officers who had proved to be failures, and in dislike of some of his ablest generals. He committed the great mistake, too,

of directing the movements of distant armies from the seat of government, though those armies were under able generals. This naturally caused great dissatisfaction, and more than once resulted in irreparable disaster.

Only two instances need be cited. In the winter of 1861–62 General Thomas J. ("Stonewall") Jackson was in command of the Valley forces. He planned and executed a brilliant winter attack on Romney in Hampshire county, occupied by the Federals, and during his march destroyed a dam on the Chesapeake and Ohio Canal, an important feeder to Washington. The position gained was very important in the defence of the Valley of Virginia. General Loring, with a part of the command, was left at Romney to hold the advantages gained. But he communicated with the War Department, and requested to be allowed to retire, on the plea that he might be cut off, although Jackson was within supporting distance. Thereupon, the administration, without consultation with General Jackson, ordered Loring's withdrawal, which resulted in a serious disadvantage in the defence of the Valley. General Jackson at once tendered his resignation, and it was with the greatest difficulty that the Governor of Virginia, with something like an apology from the War Department, was able to retain for the Confederacy the services of this great military genius. In 1864 General Joseph E. Johnston, in command of the army of Tennessee, was faced by General Sherman with nearly double his force. Johnston eluded Sherman's efforts to outflank him, and in a series of engagements, inflicting great loss, drew him some hundreds of miles from his base. He then urged Mr Davis to send a strong body of cavalry to the rear of Sherman and destroy his line of supplies. This Mr Davis declined to do, but instead insisted on Johnston's stopping the advance of his opponent. General Sherman commanded the best of the Federal troops, and Johnston, having reached Atlanta and having prepared to defend it on his own chosen ground, declined to say what his future movements might be, as they were dependent on the fortunes of war. Whereupon Mr Davis relieved him and placed in command General J. B. Hood, a greatly inferior soldier, who, in a series of wild assaults on Sherman, soon shattered the magnificent army which Johnston had led with such ability.

The defeats of Hood hastened the fate of the Confederacy. During the winter of 1864–65 the resources of the Government showed such exhaustion that it was apparent that the end would come with the opening of the Spring campaign. This was clearly stated in the reports of the Heads of Departments and of General Lee. President Davis, however, acted as if he was assured of ultimate success. He sent Duncan F. Kenner as special commissioner to the courts of England and France to obtain recognition of the Confederacy on condition of the abolition of slavery. When a conference was held in Hampton Roads on 3rd February 1865 between President Lincoln and Secretary Seward on the one side, and A. H. Stevens, R. M. T. Hunter, and Judge James A. Campbell, representing President Davis, on the other, he instructed his representatives to insist on the recognition of the Confederacy as a condition to any arrangement for the termination of the war. This defeated the object of the conference, and deprived the South of terms which would have been more beneficial than those imposed by the conqueror when the end came a few weeks later. The last days of the Confederate Congress were spent in recriminations between that body and President Davis, and the popularity with which he commenced his administration had almost entirely vanished.

After the surrender of the armies of Lee and Johnston in April 1865, President Davis attempted to make his way through Georgia across the Mississippi, in the vain hope of continuing the war with the forces of Generals Smith and Magruder. He was taken prisoner by Federal troops before he reached the river, and was brought back to Old Point, Virginia, that he might be confined in prison at Fortress Monroe. His prison was a casemate under a damp parapet, in which a light was kept constantly burning, and sentinels paced backwards and forwards continually. He was heavily chained, and his coarse food was served in filthy vessels. He entered the prison a feeble man, and such treatment soon brought him to death's door. Dr Craven, the Federal surgeon who attended him, by earnest pleas had his treatment changed and saved his life. Persistent efforts were made to connect him with the assassination of President Lincoln and with the harsh treatment of prisoners at Andersonville, but without avail. Two indictments were found against him for treason, and for several years he was denied trial or bail. Such cruel treatment aroused the sympathy of the Southern people, who regarded him as a martyr to their cause, and in a great measure restored him to that place in their esteem which by his blunders he had lost. It also aroused a general feeling in the North, and when finally he was admitted to bail, Horace Greely, Cornelius Vanderbilt, Gerrett Smith, and others in that section who had been his political opponents, became his sureties. Charles O'Conor, a leader of the New York Bar, volunteered to act as his counsel. With him was associated Robert Ould of Richmond, a lawyer of great ability. They moved to quash the indictment on which he was brought to trial. Chief Justice Chase and Judge Underwood constituted the court, which was divided, the Chief Justice voting to sustain the motion and Underwood to overrule it. The matter was thereupon certified to the Supreme Court of the United States, and no decision of which there is record was ever announced by that high tribunal. Meanwhile the administration dismissed the prosecution and discharged the accused. The health of Mr Davis was greatly injured by the harsh treatment inflicted on him while at Fortress Monroe, a harrowing account of which is given by the Federal surgeon Dr Craven in his *Prison Life of Jefferson Davis.* It was some years before he was sufficiently recovered to write his *Rise and Fall of the Confederate States of America.* In this volume he attempted to vindicate his administration, and in so doing he attacked the records of those generals he disliked. He died on 6th December 1889 at New Orleans, leaving a widow and two daughters—Margaret, who married J. A. Hayes, and Varina, better known as "Winnie" Davis, the "daughter of the Confederacy," who died unmarried in 1899.

The life of Jefferson Davis has been written several times. The most prominent of these publications are those by J. William Jones, D.D., and by Mrs Varina Davis, his widow. But his life is so prominently identified with the struggle between the States, that every history of that great contest must present him in the foreground. (W. W. H*.)

**Dawlish,** a seaside resort in the Ashburton parliamentary division of Devonshire, England, 11 miles south by east of Exeter by rail. A masonic hall was built in 1890. A dispensary was established in 1885, and an infirmary in 1896. The cottage hospital, founded in 1871, was removed to other premises in 1880. The area of the civil parish is 5370 acres. The population in 1881 was 4595, and in 1891 it was 4925. The area of the urban district is 1500 acres. The population in 1881 was 3977; in 1901, 4003.

**Dawson, Sir John William** (1820–1899), Canadian man of science, was born at Pictou, Nova Scotia, on 30th October 1820. Of Scottish descent, he went to Edinburgh to complete his education, and graduated at

that university in 1842. Returning to Canada he carried out some geological explorations under the direction of Sir Charles Lyell, and was afterwards appointed superintendent of education for Nova Scotia, a position in which he was responsible for important reforms in the educational arrangements of the province. From 1855 to 1893 he was principal of M'Gill University, which prospered under his fostering care and attained a reputation that was a good deal more than local. When the Royal Society of Canada was constituted he was the first to occupy the presidential chair, and he also acted as president of the British Association at its meeting at Birmingham in 1866, and of the American Association for the Advancement of Science. Sir William Dawson's name is especially associated with the *Eozoon Canadense*, which in 1865 he described as an organism existing in a fossil state in the Laurentian rocks, but his views on the subject were far from commanding general assent. Besides many memoirs published in the *Transactions* of various learned societies, he was the author of numerous popular books on geological subjects. In these he maintained a distinctly theological attitude, declining to admit the descent or evolution of man from brute ancestors, and holding that the human species only made its appearance on this earth within quite recent times. He died on 20th November 1899. His son, George Mercer Dawson (1849–1901), was born at Pictou on 1st August 1849, and received his education at M'Gill University and the Royal School of Mines, London, where he had a brilliant career. In 1873 he was appointed geologist and naturalist to the North American Boundary Commission, and two years later he joined the staff of the Geological Survey of Canada, of which he became assistant director in 1883, and director-general in 1895. He was in charge of the Canadian Government's Yukon Expedition in 1887, and as one of H.M. Bering Sea Commissioners spent the summer of 1891 investigating the facts of the seal fisheries on the northern coasts of Asia and America. For his services there, and at the subsequent arbitration in Paris, he was made a C.M.G. He died on 2nd March 1901. He was the author of many scientific papers and reports, especially on the surface geology and glacial phenomena of the northern parts of America, and he was largely responsible for the Canadian articles in this *Supplement*.

**Dax,** chief town of arrondissement, in the department of Landes, France, 35 miles west-south-west of Mont-de-Marsan, with station on railway from Bordeaux to Bayonne. It is an important market for resinous substances, cattle, mules, and horses, and has considerable mercantile interchange with Spain. In the middle of the town there is a hot sulphur spring of a temperature of 140° Fahr.; and the place is consequently frequented by visitors for the sake of the baths. An important new bathing establishment, beautifully situated on the site of the old castle and near the Adour, was opened by the President of the Republic in 1891. In the same year a monument to the engineer Borda (d. 1799) was unveiled. Population (1881), 8359; (1891), 8403; (1896), 8307, (comm.) 9836; (1901), 10,329.

**Dayton,** a city of Campbell county, Kentucky, U.S.A., on the south bank of the Ohio river, opposite Cincinnati, and adjoining Bellevue and Newport, Ky., in the northern part of the state. Population (1890), 4264; (1900), 6104, of whom 655 were foreign-born and 63 negroes.

**Dayton,** capital of Montgomery county, Ohio, U.S.A., in 39° 44′ N. lat. and 84° 08′ W. long., on the Great Miami river, which here is not navigable, at an altitude of 737 feet. The site is level, and the streets broad, with a fairly regular plan, and paved with gravel. It is supplied with water by the Holly pumping system, the works being owned by the city. Dayton is a commercial city of importance, being on the Miami and Erie Canal, and on ten lines of railway, belonging to five railway companies, and radiating in all directions. Its manufactures are large and varied. In 1890 the invested capital was $13,470,000, employing over 12,000 hands. The product was valued at $22,446,572. The more prominent of the products were agricultural implements, flour, and iron and steel goods. The assessed valuation of real and personal property, on a basis of about 55 per cent. of the full value, was, in 1899, $42,565,200, the net debt of the municipality, $3,562,943, and the rate of taxation, $25·60 per $1000. The city had a slow growth between 1870 and 1880, but from then until 1900 it increased rapidly, owing to the development of manufactures and trade. Population (1880), 38,678; (1890), 61,220; (1900), 85,333, of whom 10,053 were foreign-born and 3387 negroes. The death-rate in 1900 was 16·5.

**Deacon.**—The germ of the Christian diaconate may be seen in the choosing of the Seven (Acts vi.), whose primary function was "to serve tables"; but its definite and permanent shape comes from the Greek churches founded by St Paul. The ministers of these formed two distinct classes, "those who rule" and "those who serve," with the designations ἐπίσκοποι and διάκονοι; and St Paul enumerates their qualifications in 1 Tim. iii. 8–13, &c. With the development of the episcopate (in the later sense), the deacons became the immediate ministers of the bishop for disciplinary purposes; and their primary function was extended to include supervising church property, visiting the sick, distributing alms, &c. By degrees these became subsidiary to another function, that of ministering in the church, especially in Baptism and the Eucharist, and later on that of teaching too. And thus the duties of the deacon came to be summed up as follows in the Roman Pontifical: *diaconus oportet ministrare ad altare, baptizare et prædicare.* (In the English Ordinal both functions, ministering in temporal matters and ministering in the congregation, are kept in view.) But the fundamental character of his office remained: on the one hand he was sharply distinguished, as being in "holy orders" like the bishop and presbyter, from the various lower orders in the ancient Church; on the other hand, he "ministered" to those of higher degree. And although in their absence fresh functions devolved upon him (varying with times and regions), he could never perform strictly "sacerdotal" functions, such as consecrating the Eucharist. The office frequently led in ancient days to the higher orders; but it was frequently held for life, and in great cities, where the number of deacons was long restricted to seven, it became one of high honour and emolument. In modern days both tendencies are represented: in the West the office is usually a stepping-stone to the priesthood, whereas in the East it is often held for life, and some high offices are reserved to deacons. The ancient canonical age for the diaconate was twenty-five; it is now twenty-three. In the Lutheran Churches the *Diakonat* is merely a title of certain assistant clergy, not a separate order; in most other non-Episcopal Churches it is practically a lay office.

Sohm. *Kirchenrecht*, i. 121–137. Leipzig, 1892.—Smith and Cheetham. *Dictionary of Christian Antiquities*, art. "Deacon." (W. E. Co.)

**Deaconess.**—The office of deaconess has a special importance at the present day, in view of the movement for its revival. It may now be considered certain that (*a*)

there was a true diaconate of women in the churches founded by St Paul. Bishop Lightfoot held that Phœbe, διάκονος of the church at Cenchreæ (Rom. xvi. 1), "is as much a deacon as Stephen or Philip is a deacon"; and even if the word be used loosely here, it is clear that 1 Tim. iii. 11 means "Women (-deacons) in like manner," &c. (*b*) Nor must they be confused with the "widows" of the ancient Church, to whom certain functions were sometimes intrusted; they were ordained (excepting apparently for a time in Egypt) and had a definite position "about the altar," *i.e.*, in the ranks of the clergy. Their work was to visit and instruct the women, to have charge of them during service, and to anoint women and children for baptism; sometimes also to cleanse the sanctuary and even administer the chalice to women. At first they ranked with, but below, the men-deacons; in course of time, however, the former rose in the scale and the latter fell, ranking below the sub-deacons; and indeed the author of the TESTAMENTUM DOMINI (*q.v.*) places over them an entirely new officer, the "canonical widow," "presbytera," or "*vidua habens præcedentiam sedendo*," of whom there are only faint traces elsewhere. Although the order appears to have existed from the first in the East, where women were much secluded (the two *ministræ* tortured by Pliny, *Ep.* xcvi, may well have been deaconesses), it only spread elsewhere by degrees. It is not mentioned in Egypt till well on in the 3rd century, and does not appear in the West till about 400 A.D.,—first in Gaul and then in Italy. Even then it does not seem to have been a thriving institution. Some deaconesses are known to us of a strictly ministerial kind, but more frequently they are of a monastic or *quasi*-monastic character; and the institution died away by about the 11th century. In the East they throve better: they are well known to us in the writings of St Chrysostom and other fathers, synods made regulations respecting them, and their position before the law is clearly laid down in the Civil Law. Nevertheless, here also they passed away by degrees; first the office came to be held by the heads of communities of women, then the name came to be given to abbesses in general, and by about the 13th century deaconesses were practically extinct. Several mediæval and Protestant sects, however, possessed a ministry of deaconesses, amongst whom may be mentioned the Cathari, Mennonites, United Brethren, and the early Independents. Moreover, the enlarged scope of women's work at the present day has led to the foundation of "deaconess institutions" of an entirely new kind. Such an institution was inaugurated at Kaiserwerth in 1833 by the Lutheran Dr Fleidner; others of the same kind followed, both abroad and in England (*e.g.*, at Tottenham and Mildmay Park); and they are now to be found in most parts of Europe. The members of these institutions, however, do not really represent the deaconesses of early days: they are not ministers of their churches in any real sense, but rather members of voluntary societies for common work. In fact they are Protestant sisters of charity rather than deaconesses. In recent days, however, there has been a movement in the churches of the Anglican communion for the revival of the order of deaconess on ancient lines. In 1861 Bishop Tait of London set apart Miss E. Ferard as a deaconess by laying on of hands, and she became the first head of the London Deaconess Institution. Similar institutions have since been founded at home and abroad, some on a "regular" and some on a "secular" basis; *i.e.*, in some cases the members are professed sisters, in others not. By degrees, too, they have received further recognition. In 1871 a body of "Principles and Rules" for deaconesses received the signature of the two English archbishops and eighteen bishops; in 1891 eight "Resolutions" on the subject were passed in the Convocation of Canterbury; and the Lambeth Conference of 1897 "recognizes with thankfulness the revival of the office of deaconess." Nevertheless, the revival cannot yet be considered complete: the deaconess is not yet more than a diocesan officer, who "may be released from her obligations by the bishop, if he thinks fit, upon cause shown"; her special functions are undetermined, and her status is still in many ways indefinite. No doubt, however, further development is only a question of time.

(W. E. CO)

**Dead Sea,** a lake in Palestine, so called from the absence of animal life in its waters. It lies nearly north and south, in the deepest part of the Jordan-Araba depression. It has no outlet, and its surface is from 1289 to 1300 feet below that of the Mediterranean. At its northern end is the broad valley down which the Jordan flows; and beyond the marshy plain at its other extremity, the floor of the Araba rises southward to the watershed between the Dead and Red Seas (65½ miles from the Dead and 46½ miles from the Red Sea; altitude 660 feet). From the eastern shore the ground rises abruptly in terraces to the Moabite plateau (3100 feet); and from the western with almost equal abruptness to the hill country of Judah (3300 feet). The slopes on either side are deeply seamed by watercourses, through which winter torrents and, in some cases, perennial streams flow to the lake. The Dead Sea is about 47½ miles long, and its greatest width is 9½ miles; its area is about 340 square miles. It is divided into two unequal parts by a peninsula, el-Lisán, which breaks off on the west in a cliff about 300 feet high, and is connected with the Moabite shore by a narrow strip of marshy land. The peninsula is composed of white calcareous marl with beds of salt and gypsum, and, like Jebel Usdum, which it resembles in character and composition, it formed part of the bed of the lake when its waters stood at a higher level. North of the peninsula the lake has a maximum depth of 1278 feet. South of it the depth is only 3 to 12 feet, and some years ago it was fordable opposite el-Lisán. The marshy plain, es-Sebkha, at the south end is liable to inundation, and strewn with driftwood encrusted with salt; it extends southwards to a terrace 500 feet high, which marks the commencement of the 'Araba. At the south-west end of the lake is Jebel or Khashm Usdum, about 600 feet high, and 7 miles long, of which the lower part is formed of solid rock-salt. The principal affluents, including winter torrents, are, on the north, the Jordan and 'Ain es-Súeimeh; on the east, Wadies Ghuweir, Zerka Ma'ín, in which lie the hot sulphur springs of Callirrhöe, Mójib (Arnon), ed-Derá'a or el-Kerak, en-N'meirah, and el-Hesi or es-Sáfieh, which passes to the lake through the reed-thickets of es-Sebkha; on the south, Wadies et-Tafíleh, el-Jeib, and el-Fikreh; and on the west, Wadies Muhauwát and Seyál, 'Ain Jidi, W. el-Merabba or ed-Derajeh, 'Ain Ghuweir, W. en-Nár, and 'Ain Feshkha. It is estimated that these affluents pour more than six million tons of water into the Dead Sea daily, all of which passes off by evaporation.

The surface level of the lake varies with the season. In March 1865 it was 1292 feet below sea-level (Wilson): it is highest in February or March. The boiling-point of the water is 221° F. The density increases from north to south, and with the depth—rapidly to a certain point, after which it is more uniform. Its density at 300 *mètres* is 1·253, average 1·166. The solid matter at a depth of

300 m. is 27·8 per cent. of the weight, and consists of chlorides of calcium, magnesia, sodium, and potassium, and in smaller proportions of bromides and sulphates of the same substances. The richness in bromine is held to indicate greatly prolonged concentration. Eggs float in the water. Curative properties were attributed to it in Roman times; and according to Mukaddasi, A.D. 985, people assembled to drink it on a feast day in August. A bath in the lake is wholesome and refreshing. The oily sensation after bathing is due to the chloride of calcium; and the noisome, acrid taste to the chloride of magnesia. The chloride and bromide of magnesia are fatal to all animal life excepting certain microbes found in the mud by Ehrenberg and Lortet. Fish carried down by the Jordan, and small fish from brackish pools and streams near the shore, die at once in the water of the lake. The water strongly affects the eyes, and evaporation leaves a thick deposit of salt. The water is limpid and transparent, and under varying conditions is deep blue or green in colour. Its surface, far from being motionless, as some writers have supposed, is constantly rippled by breezes, or raised into waves by the strong northerly winds, and is sometimes veiled by light bluish clouds or haze produced by the evaporation. Molyneux, in 1847, and others since that date, have noticed a streak of white foam which sometimes stretches from the north-west end of the lake towards el-Lisán, following nearly the axis of the lake. From this Blanckenhorn concludes that there is a sub-lacustrine fissure which he considers to be thermal and asphaltic; but the phenomenon is possibly due to the current of the Jordan, which does not expend its force completely until it reaches el-Lisán. A recent traveller, Rev. P. Cady, writes of a strong current setting towards the north along the east coast; of oil floating on the water near the mouth of the Zerka Ma'în; and of disturbances of level that appear, like those to which the Lake of Geneva is subject, to be due to differences of barometric pressure at different points on the lake. The origin of these and other phenomena can only be ascertained by a thorough scientific examination of the lake and its basin. The shores are sterile and desolate from the absence of fresh water, and from the smallness of the rainfall, and not, as formerly supposed, from the poisonous nature of the air. The springs near the lake give life to thickets of willow, tamarisk, and acacia, which are frequented by birds; and wherever, as at Engedi, there is running water the vegetation is almost tropical in its luxuriance. The plain of Jericho is very fertile, and south of the lake the Arabs raise crops of wheat, dura, cotton, and tobacco. The climate in summer and autumn is very hot and unhealthy; but in winter it is good, with hot days and cool nights. The unhealthiness is due partly to the intense heat, and partly to the miasma from the swamps and lagoons at the southern end. The scenery is remarkable for the brilliancy of the colouring, and the varying effects of light and shade. The abrupt slopes on either side, the deep ravines on the eastern shore, and the intense colouring of the water combine to form a scene of grandeur and beauty which has been compared, not inaptly, with the aspect of some portions of the Lake of Geneva. Boats were employed on the lake in Roman, and possibly in much earlier, times (Tacitus, *Hist.* v. 6; Josephus, *Ant.* ix. 1, § 2; *B. J.* iv. 7, § 6); they are represented on it in the mosaic map at Medeba; and under the Latin Kingdom of Jerusalem the navigation dues formed part of the revenue of the Lords of Kerak. The use of boats died out when the Turks abandoned the country east of the Jordan to the Bedawín. During the 19th century boats have occasionally been used for exploration, and since the occupation of Moab and Edom by the Turks an attempt has been made to place small steamers on the lake.

*Name.*—In the Old Testament the Dead Sea is called "the sea," the "salt sea," the "sea of the Arabah," and "the eastern sea." The name "Dead Sea" appears in the Vulgate (Jos. iii. 16), and is used by Pausanias, Galen, Justin, and Eusebius. Diodorus Siculus, Pliny, and Josephus call it the "Asphaltic Lake," and others the "Sodomitish sea." It is now known to the Arabs as Bahr Lût, "the sea of Lot."

*Geology.*—The Jordan-Araba depression, in which the Dead Sea lies, was produced by subsidence along a line of faults or fractures during the terrestrial movements that accompanied the gradual elevation of the region out of the sea after the close of the Eocene period. As a result of the faulting, the formations on the opposite sides of the lake do not correspond. Whilst the hills on the western side are formed entirely of Cretaceous limestones, the abrupt face of the Moabite plateau is composed of a base of ancient volcanic rocks, upon which rest, in ascending order, red sandstones and conglomerates of the Carboniferous age, Carboniferous limestone, variegated sandstones (Nubian sandstone) of Lower Cretaceous age, and Cretaceous limestones. The deeply cut ravines of the Moabite plateau owe their origin to the same subsidence, but their features, and those of the hills east and west of the lake, were greatly modified by the heavy rainfall in the Pliocene and Pleistocene periods. Terraces of lacustrine deposits at different levels indicate that in Pleistocene times the Jordan valley was occupied by a lake 200 miles long, which had the same surface level as the Mediterranean; and that the water gradually subsided until, long before the dawn of history, the evaporation equalled the supply, and the lake assumed approximately its present level. The surface is liable to frequent fluctuations of level, which, though confined to narrow vertical limits, are sufficient to alter considerably the form and superficial extent of the lake. Such fluctuations are due to a succession of exceptionally dry or rainy seasons, to the greater or lesser activity of subaqueous springs, to landslips, to changes in the drainage, to the gradual silting up of the basin, and, possibly, to slight earth movements which escape detection. The annual rise and fall is estimated at from 6 to 10 feet, but there seems to be also prolonged periods of high and low level. The lines of driftwood and the marks on the rocks show the limits of rise which might occur under existing conditions, and a fall of 15 feet is quite possible after exceptional periods of dryness. Such a fall would dry up almost the whole of the lagoon south of el-Lisán, and effect great changes in the appearance of the lake. During the forty years 1860–1900 there was a gradual rise in the level of the surface, apparently coinciding in part with a succession of wet seasons, but accurate observations are wanting. A small island near the north end of the lake, which in 1858 was from 10 to 12 feet above the surface, and connected with the shore by a causeway, has been entirely submerged since 1892; and the track between Jebel Usdum and the lake has for several years been covered with water. Monthly measurements of the rise and fall of the lake, taken for the Palestine Exploration Fund during an exceptionally dry year, October 1900 to October 1901, showed a rise of 1 foot 3 inches up to 30th March 1901, and then a fall of 1 foot 9 inches to October. Thus the level of the lake was lowered 6 inches during the year. The asphalt or bitumen, so highly prized in ancient times, is supposed to be derived from subaqueous strata of bituminous limestone or marl, and to collect at the bottom of the lake until it is loosened by an earthquake and rises to the surface. The Arabs collect the bitumen which reaches the shore, and the salt of Jebel Usdum and of the Dead Sea has been carried to Jerusalem from the earliest times. But no systematic attempt has been made yet to turn the mineral wealth of the Dead Sea and its basin to account.

The following analysis of water taken from the north end of the lake, not near the Jordan, in March 1885, when the level was high, was made by Dr Bernays:—

Sp. gr. 1·1528 at 15·5 C.

| | Grs. |

| | 15,260·00 grains residue per gallon. |

This is not the place to discuss the theories respecting the destruction of the Cities of the Plain (Gen. xix.). The catastrophe was in no way connected with the formation of the Dead Sea. Some authorities place the cities at the south end of the lake; but it is clear from the statements in the Bible that they were situated in the Jordan valley to the north of the lake.

**Deadwood,** capital of Lawrence county, South Dakota, U.S.A., in the northern part of the Black Hills, in 44° 23′ N. lat. and 103° 44′ W. long., in the cañon of Whitewood Creek, at an altitude of 4532 feet. Its site is hilly, and its street plan irregular. It has two railways, the Burlington and Missouri River, and the Fremont, Elkhorn, and Missouri Valley. It is the commercial and mining centre of the Black Hills. About it are several gold mines, characterized by the low grade of their ores, which range from $3 to $4 per ton, by their vast quantity and by the ease of mining and of extracting the metal. The ore contains free gold, which is extracted by the simple process of stamping and amalgamation. Several hundred tons of ore are treated thus in Deadwood and its environs daily, and its stamp mills are exceeded in size only by those of the Treadwell Mine in south-eastern Alaska. The annual gold product of this region is about $4,000,000. Population (1880), 3777; (1890), 2366; (1900), 3498, of whom 707 were foreign-born.

**Deal,** a municipal borough and bathing resort in the St Augustine's parliamentary division (since 1885) of Kent, England, 8 miles north-east by north of Dover by rail. The asphalted promenade is now nearly 4 miles long; the pier has been provided with a pavilion and enlarged. There are well-known golf links. Area, 1124 acres. Population (1881), 8500; (1901), 10,427. There is a parish of Deal.

**De Amicis, Edmondo** (1846——), Italian writer, was born at Oneglia 21st October 1846. After some schooling at Cuneo and Turin, he was sent to the Military School at Modena, from which he was appointed to a lieutenancy in the 3rd Regiment of the line in 1865. He fought at the battle of Custozza in 1866. In 1867 he became Director of the *Italia Militare*, Florence. In the following year he published his first book, *La Vita Militare*, which consisted of sketches of military life, and attained wide popularity. After the overthrow of the Pope's temporal power in 1870, De Amicis retired from the army and devoted himself to literature, making his headquarters at Turin. Always a traveller by inclination, he found opportunity for this in his new leisure, and some of his most popular books have been the product of his wanderings. Several of these have been translated into English and the other principal languages of Europe. The most important of these are his descriptions of Spain (1873), Holland (1874), Constantinople (1877), and Morocco (1879). These have gained him reputation as a brilliant depicter of scenery and the external aspects of life; solid information is not within their sphere; and much of their success is owing to the opportunities they afford for spirited illustration. Of late years De Amicis has greatly extended his fame as a novelist, especially by *Il Romanzo d'un Maestro* (1890). His poems consist principally of sonnets.

**De Bary, Anton** (1831–1888), German botanist, was of Belgian extraction, but his family had long been settled in Germany. He was born, January 26, 1831, at Frankfort-on-Main. From 1849 to 1853 he studied medicine at Heidelberg, Marburg, and Berlin. In 1853 he settled at Frankfort as a surgeon. In 1854 he became *privat-docent* for botany in Tübingen, and afterwards Professor of Botany at Freiberg (1859). In 1867 he migrated to Halle, and in 1872 to Strassburg, where he was the first rector of the newly constituted university. He died there January 19, 1888. In his earlier years he came under the influence of Mohl, Fresenius, A. Braun, Ehrenberg, and Johannes Müller, but his startling originality and ability soon brought him into prominence, and he became one of Germany's most distinguished biologists, remarkable for his broad and firm grip of the botanical problems of his day, and for the clear insight he brought to bear on investigations.

Although one of his largest and most important works was on the *Comparative Anatomy of Ferns and Phanerogams*, in which he produced an account of the tissues of vascular plants which has never been entirely superseded, his treatment of the epidermal system being especially good, and notwithstanding his admirable acquaintance with systematic and field botany generally, De Bary will always be remembered as the founder of modern Mycology. This branch of botany he completely revolutionized in 1866 by the publication of his celebrated *Morphologie und Physiologie d. Pilze*, &c., a classic which he rewrote in 1884, and which has had a world-wide influence on Biology. His clear appreciation of the real significance of *Symbiosis* and the dual nature of Lichens stands out as one of his masterpieces, and in many ways he showed powers of generalizing in regard to the evolution of organisms which would alone have made him a distinguished man. It was as an investigator of the then mysterious Fungi, however, that De Bary stands out first and foremost among the biologists of the 19th century. He not only laid bare the complex facts of the life-history of many forms, —*e.g.*, the Ustilagineæ, Peronosporeæ, Uredineæ, and many Ascomycetes,—treating them from the developmental point of view, in opposition to the then prevailing anatomical method of the Tulasnes, but he insisted on the necessity of tracing the evolution of each organism from spore to spore, and by his methods of culture and accurate observation brought to light numerous facts hitherto undreamt of. These his keen perception and insight continually employed as the basis for hypotheses, which he in turn tested with an experimental skill and critical faculty rarely equalled and probably never surpassed. One of his most fruitful discoveries was the true meaning of infection as a morphological and physiological process. He traced this step by step in *Phytophthora*, *Cystopus*, *Puccinia*, and other Fungi, and so placed before the world in a clear light the significance of parasitism. He then showed by numerous examples wherein lay the essential differences between a parasite and a saprophyte, a theme by no means clear in 1860–70, but which he himself had recognized as early as 1853, as is shown by his work, *Die Brandpilze*.

These researches led to the explanation of epidemic diseases, and De Bary's contributions to this subject were fundamental, as witness his classical work on the Potato Disease in 1861. They also led to his striking discovery of *heterœcism* (or *metœcism*) in the Uredineæ, the truth of which he demonstrated in Wheat Rust experimentally, and so clearly that his classical example (1863) has never been other than confirmed by subsequent observers, though we now know much more as to details. It is difficult to estimate the relative importance of De Bary's astoundingly accurate work on the sexuality of the Fungi. He not only described the phenomena of sexuality in Peronosporeæ

and Ascomycetes,—*Eurotium, Erysiphe, Peziza,* &c.,—but also established the existence of Parthenogenesis and Apogamy on so firm a basis that it is doubtful if all the combined workers who have succeeded him, and who have brought forward contending hypotheses in opposition to his views, have succeeded in shaking the doctrine he established before modern cytological methods existed. In one case, at least (*Pyronema confluens*), the most recent and skilful investigations, with every modern appliance, have shown that De Bary described the sexual organs and process accurately.

It is impossible here to mention all the discoveries made by De Bary. He did much work on the Chytridieæ, Ustilagineæ, Exoasceæ, and Phalloideæ, as well as on that remarkable group the Myxomycetes, or, as he himself termed them, *Mycetozoa*, almost every step of which was of permanent value, and started lines of investigation which have proved fruitful in the hands of his pupils. Nor must we overlook the important contributions to Algology contained in his earlier monograph on the Conjugatæ (1858), and investigations on Nostocaceæ (1863), *Chara* (1871), *Acetabularia* (1869), &c. De Bary seems to have held aloof from the Bacteria for many years, but it was characteristic of the man that, after working at them in order to include an account of the group in the second edition of his book in 1884, he found opportunity to bring the whole subject of Bacteriology under the influence of his genius, the outcome being his brilliant *Lectures on Bacteria* in 1886. De Bary's personal influence was immense. Every one of his numerous pupils was enthusiastic in admiration of his kind nature and genial criticism, his humorous sarcasm, and his profound insight, knowledge, and originality.

Memoirs of De Bary's life will be found in *Bot. Centralbl.* 1888, vol. xxxiv. p. 93, by Wilhelm; *Ber. d. d. bot. Ges.* vol. vi., 1888, p. viii, by Reess, each with a list of his works; *Bot. Zeitung*, 1889, vol. xlvii., No. 3, by Graf zu Sohms-Laubach. (H. M. W.)

**Debentures** and **Debenture Stock.**—An advantage incident in Great Britain to incorporation under the Companies Acts is found in the facilities which it affords a trading concern for borrowing on debentures or debenture stock. More than four hundred millions of money are now invested in these forms of security. Borrowing is not specifically dealt with by the Companies Acts at all, but that it was contemplated by the Legislature is evident from the provision in sect. 43 of the Act of 1862 for a company keeping a register of mortgages and charges. The policy of the Legislature in this, as in other matters connected with trading companies, was apparently to leave the company to determine whether borrowing should or should not be one of the objects defined expressly or by implication in the memorandum of association. A company cannot borrow unless it is expressly or impliedly authorized to do so by its memorandum. In the case of a trading company borrowing is impliedly authorized as a necessary incident of carrying on the company's business. Thus a company established for the conveyance of passengers and luggage by omnibuses, a company formed to buy and run vessels between England and Australia, and a company whose objects included discounting approved commercial bills, have all been held to be trading companies with an incidental power of borrowing as such to a reasonable amount. A building society, on the other hand, has no inherent power of borrowing, though a limited statutory power was conferred on such societies by the Building Societies Act, 1874; nor has a society formed not for gain but to promote art, science, religion, charity, or any other useful object. Public companies again, formed to carry out some undertaking of public utility, such as docks, water-works, or gas-works, and governed by the Companies Clauses Acts, have only limited powers of borrowing.

The indefiniteness of an implied power of borrowing, even when it attaches, has led to a general power of borrowing being usually inserted in a company's memorandum of association. It is left to the articles to define the amount to be borrowed, the nature of the security, and the conditions, if any, such as the sanction of a general meeting of shareholders, on which the power is to be exercised. Under the Companies Act, 1900, a company cannot exercise any borrowing power until it has fulfilled the conditions prescribed by the Act entitling it to commence business. A person who is proposing to lend money to a company must be careful to acquaint himself with any regulations of this kind, and to see (1) that the memorandum and articles of association authorize borrowing, and (2) that the borrowing limit is not being exceeded, for if it should turn out that the borrowing was in excess of the company's powers and *ultra vires*, the company cannot be bound, and the borrower's only remedy is against the directors for breach of warranty of authority, or to be surrogated to the rights of creditors paid out of the borrowed moneys. A company proposing to borrow usually issues a prospectus, similar to the ordinary share prospectus, stating the amount of the issue, the dates for payment, the particulars of the property to be comprised in the security, the terms as to redemption, and so on, and inviting the public to subscribe. Underwriting is also resorted to, as in the case of shares, to insure that the issue is taken up. There is no objection to a company issuing debentures or debenture stock at a discount, as there is to its issuing its shares at a discount. It must borrow on the best terms it can get. A prospectus inviting subscriptions for debentures or debenture stock comes within the terms of the Directors Liability Act, 1890, and persons who are parties to it have the onus cast upon them, should the prospectus contain any misstatements, of showing that, at the time when they issued the prospectus, they had reasonable grounds to believe, and did in fact believe, that the statements in question were true; otherwise they will be liable to pay compensation to any person injured by the misstatements.

The usual mode of borrowing by a company is either on debentures or debenture stock. Etymologically, debenture is merely the Latin word "*debentur*,"—the first word in a document in common use by the Crown in early times admitting indebtedness to its servants or soldiers. This was the germ of a security which has now, with the expansion of joint-stock company enterprise, grown into an instrument of considerable complexity.

*The Floating Debenture.*—The form of debenture chiefly in use at the present day is that known as the floating debenture. By it the company covenants to pay to the holder thereof the sum secured by the debenture on a specified day (usually ten or fifteen years after the date of issue), or at such earlier date as the principal moneys become due under the provisions of the security, and in the meantime to pay interest until repayment, or until the security becomes enforceable under the conditions; and the company further charges its undertaking and all its property and assets, including its uncalled capital, with the payment of the amount secured by the debentures. The word "property" by itself will not cover uncalled capital. This is the body of the instrument; on its back is endorsed a series of conditions, constituting the terms on which the debenture is issued. Thus the debenture-holders are to rank *pari passu* with one another against the security; the debenture is to be transferable free from equities between the company and the original holder; the charge is to be a floating charge, and is to be enforce-

able in certain events: for instance, if the interest is in arrear for three months, or if a winding up order is made against the company, or a resolution for winding up is passed. Other events are sometimes added accelerating payment. The conditions also provided for the mode and form of transfer of the debentures, the death or bankruptcy of the holder, the place of payment, &c. The term "floating charge" is used to distinguish it from one that is fixed. The charge attaches as soon as the debenture is issued, but it attaches to the assets for the time being only, *i.e.*, it leaves the company free (or, to put it otherwise, gives it a licence) to sell, mortgage, lease, and otherwise deal with such assets as if no charge existed. This licence is involved in the fact that the debenture-holders' charge is on the company's undertaking, which implies that the undertaking is to remain a going concern. The licence extends, however, only to dealings in *the ordinary course of business;* it does not entitle a company to sell the whole of its undertaking and assets. Payment by a company of its just debts is always in the ordinary course of business, but satisfaction by execution levied *in invitum* is not.

Every debenture must now, under the Companies Act, 1900, bear the registrar's certificate of registration. This floating form of security is found very convenient both to the borrowing company and to the lender. The company is not embarrassed by the charge, while the lender has a security covering the whole assets for the time being, and can intervene at any moment by obtaining a receiver if his security is imperilled, even though none of the events in which the principal moneys are made payable have happened. If any of them has happened, *e.g.*, default in payment of interest, or a resolution by the company to wind up, the payment of the principal moneys is accelerated, and a debenture-holder can at once commence an action to obtain payment and to realize his security. At times a proviso is inserted in the conditions endorsed on the debenture, that the company is not to create any mortgage or charge ranking in priority to or *pari passu* with that contained in the debentures without the consent of the debenture-holders.

*Trust Deeds.*—When the amount borrowed by a company is large, and it is not meant that it should be soon paid off, it is very common for the company to execute a Trust Deed by way of further security. The object of such a trust deed is twofold: (1) it conveys specific property to the trustees of the deed by way of legal mortgage (the charge contained in the debentures is only an equitable security), and charges all the remaining assets in favour of the debenture-holders, with appropriate provisions for enabling them, in certain events similar to those expressed in the debenture conditions, to enforce the security, and for that purpose to enter into possession and carry on the business, or to sell it and distribute the profits; (2) it organizes the debenture-holders and constitutes in the trustees of the deed a set of experienced and business-like men who can watch over the interests of the debenture-holders and take steps for their protection if necessary. In particular it provides machinery for the calling of meetings of debenture-holders by the trustees, and empowers a majority of (say) two-thirds or three-fourths in number and value at such meeting to bind the rest to any compromise or arrangement with the company which such majorities may deem beneficial. This is found a very useful power, and may save recourse to a scheme of arrangement under the machinery of the Joint-Stock Companies Arrangement Act, 1870.

*Registration of Mortgages and Charges.*—A company is bound, under the Companies Act, 1862, to keep a register of mortgages and charges, open for the inspection of creditors. It is also bound now, under the Companies Act, 1900, to register with the registrar of joint-stock companies at Somerset House all mortgages and charges of certain specified kinds made by the company, otherwise the security will be void.

*Debentures Registered and to Bearer.*—Debentures are usually of two kinds—(1) registered debentures, and (2) debentures to bearer. Registered debentures are transferable only in the books of the company. Debentures to bearer are negotiable instruments, and pass by delivery. Coupons are attached for interest. Sometimes debentures to bearer are made exchangeable for registered debentures, and *vice versâ.*

*Redemption.*—A company generally likes to reserve to itself a right of redeeming the security before the date fixed by the debenture for repayment; and accordingly a power for that purpose is generally inserted in the conditions. But as debenture-holders, who have got a satisfactory security, do not wish to be paid off, the right of redemption is usually qualified so as not to arise till (say) five years after issue, and a premium of 5 per cent. is made payable by way of bonus to the redeemed debenture-holder. The number of debentures to be redeemed each year is also limited. The selection is usually made by drawings held in the presence of the directors. A sinking fund is a convenient means often resorted to for redemption of a debenture debt. Such a fund is formed by the company setting apart a certain sum each year out of the profits of the company after payment of interest on the debentures.

*Debenture Stock.*—Debenture stock bears the same relation to debentures that stock does to shares. "Debenture stock," as Lord Lindley states (*Companies*, 5th ed. 195), "is merely borrowed capital consolidated into one mass for the sake of convenience. Instead of each lender having a separate bond or mortgage, he has a certificate entitling him to a certain sum, being a portion of one large loan." This sum is not uniform, as in the case of debentures, but variable. One debenture-stockholder, for instance, may hold £20 of the debenture stock, another £20,000. It is this divisibility of stock in fact, whether debenture or ordinary stock, into quantities of any amount, which constitutes its peculiar characteristic, and its convenience from a business point of view. It facilitates dealing with the stock, and also enables investors with only a small amount to invest to become stockholders. The property comprised in this security is generally the same as in the case of debentures. Debenture stock created by trading companies differs in various particulars from debenture stock created by public companies governed by the Companies Clauses Act. The debenture stock of trading companies is created by a contract made between the company and trustees for the debenture-stockholders, known as a debenture-stockholders' trust deed, analogous in its provisions to the trust deed above described as used to secure debentures. By this deed the company acknowledges its indebtedness to the trustees as representing the debenture-stockholders to the amount of the sum advanced, covenants to pay it, and conveys the subject matter by way of security to the trustees with all the requisite powers and provisions for enabling them to enforce the security on default in payment of interest by the company or the happening of certain specified events evidencing insolvency. The company further in pursuance of the contract enters the names of the subsisting stockholders in a register, and issues certificates for the amount of their respective holdings. A deed securing debenture stock requires an *ad valorem* stamp.

*Remedies.*—When debenture-holders' security becomes

enforceable there are a variety of remedies open to them. These fall into two classes—(1) remedies available without the aid of the Court; (2) remedies available only with the aid of the Court.

(1) If there is a trust deed, the trustees may appoint a receiver of the property comprised in the security, and they may also sell under the powers contained in the deed, or under § 25 of the Conveyancing Act, 1881. Sometimes similar powers—to appoint a receiver and to sell—are inserted in the conditions endorsed on the debenture.

(2) The remedies with the aid of the Court are—(*a*) an action by one or more debenture-holders on behalf of all for a receiver and to realize the security; (*b*) an originating summons for sale or other relief, under Rules of Supreme Court, 1883, O. 55, R. 5A; (*c*) an action for foreclosure where the security is deficient,—all the debenture-holders must be parties to this proceeding; (*d*) a winding-up petition. Of these modes of proceeding, the first is by far the most common and most convenient. The company is generally consenting, and the action comes on for judgment on agreed minutes, when the Court directs accounts and inquiries as to who are the holders of the debentures, what is due to them, what property is comprised in the security, and gives leave to any of the parties to apply in chambers for a sale. If the company has gone into liquidation, leave must be obtained to commence or continue the action, but such leave in the case of debenture-holders is *ex debito justitiæ*. The administration of a company's assets in such actions by debenture-holders (debenture-holders' liquidations, as they are called) has of late encroached very much on the ordinary administration of winding up. The chief sufferers from the floating security, when it comes to be enforced on winding up, are the company's unsecured creditors, who find that everything belonging to the company, uncalled capital included, has been pledged to the debenture-holders. The conventional answer is that such creditors might and ought to have inspected the company's register of mortgages and charges.

*Reconstruction.*—When a company reconstructs, as it often does in these days, the rights of debenture-holders have to be provided for. Reconstructions are mainly of two kinds—(1) by arrangement, under the Joint-Stock Companies Arrangement Act, 1870, and (2) by sale and transfer of assets, either under § 161 of the Companies Act, 1862, or under a power in the company's memorandum of association. Under the Joint-Stock Companies Act a petition for the sanction of the Court to a scheme is presented, and the Court thereupon directs meetings of creditors, including debenture-holders, to be held. A three-fourths majority in value of debenture-holders present at the meeting in person or by proxy binds the rest. Debenture-holders claiming to vote must produce their debentures at or before the meeting. Under the other mode of reconstruction—sale and transfer of assets—there is usually a novation, and the debenture-holders accept the security of the new company in the shape of debentures of equivalent value or—occasionally—of fully paid preference shares.

A point in this connexion, which involves some hardship to debenture-holders, may here be adverted to. It is a not uncommon practice for a solvent company to pass a resolution to wind up voluntarily for the purpose of reconstructing. The effect of this is to accelerate payment of the security, and the debenture-holders have to accept their principal and interest only, parting with a good security and perhaps a premium which would have accrued to them in a year or two. The company is thus enabled by its own act to redeem the reluctant debenture-holder on terms most advantageous to itself. To obviate this hardship, it is now a usual thing in a debenture-holders' trust deed to provide—the committee of the London Stock Exchange indeed require it—that a premium shall be paid to the debenture-holders in the event of the security becoming enforceable by a voluntary winding up with a view to reconstruction.

*Public Companies.*—Public companies, *i.e.*, companies incorporated by special Act of Parliament for carrying on undertakings of public utility, form a class distinct from trading companies. The borrowing powers of these companies, the form of their debenture or debenture stock, and the rights of the debenture-holders or debenture-stockholders, depend on the conjoint operation of the companies' own special Act and the Companies Clauses Acts, 1845, 1863, and 1869. The provisions of these Acts as to borrowing, being express, exclude any implied power of borrowing. The first two of the above Acts relate to mortgages and bonds, the last to debenture stock. The policy of the Legislature in all these Acts is the same, namely, to give the greatest facilities for borrowing, and at the same time to take care that undertakings of public utility which have received its sanction shall not be broken up or destroyed, as they would be if the mortgagees or debenture-holders were allowed the ordinary rights of mortgagees for realizing their security by seizure and sale. Hence the Legislature has given them only "the fruit of the tree," as Lord Cairns expressed it. The debenture-holders or the debenture-stockholders may take the earnings of the company's undertaking by obtaining the appointment of a receiver, but that is all they can do. They cannot sell the undertaking or disorganize it by levying execution, so long as the company is a going concern; but this protecting principle of public policy will not be a bar to a debenture-holder, in his character of creditor, presenting a petition to wind up the company, if it is no longer able to fulfil its statutory objects. Railway companies are affected by further special legislation, which will be found in the Railway Companies Powers Act, 1864, the Railways Construction Facilities Act, 1864, and the Railway Securities Act, 1866.

*Municipal Corporations and County Councils.*—These bodies are authorized to borrow for their proper purposes on debentures and debenture stock with the sanction of the Local Government Board. See the Municipal Corporations Act, 1882, the Local Authorities Loans Act, 1875, and the Local Government (England and Wales) Act, 1888.

*United States.*—In the United States there are two meanings of debenture—(1) a bond not secured by mortgage; (2) a certificate that the United States is indebted to a certain person or his assigns in a certain sum on an audited account, or that it will refund a certain sum paid for duties on imported goods, in case they are subsequently exported.

**Debreczen,** a municipal town of Hungary, 114 miles east of Budapest, with (1900) 75,006 inhabitants. The country belonging to the town forms a vast plain 370 square miles in extent, on which are few dwelling-places, but where roam hundreds of thousands of cattle, horses, sheep, and pigs.

**Debu Lake.** See NIGER.

**Decatur,** capital of Macon county, Illinois, U.S.A., near the Sangamon river, at an altitude of 668 feet. Its site is level, its street plan regular, and it has a good water supply and well paved streets. Five railways meet here, making it a commercial point of much importance. Among its manufacturing establishments are flour-mills and car shops, and in its vicinity are coal-mines. Popula-

tion (1880), 9547; (1890), 16,841; (1900), 20,754, of whom 1939 were foreign-born and 620 negroes.

**Decazeville,** a town and railway station in the arrondissement of Villefranche, department of Aveyron, France, 22 miles in direct line north-west of Rodez. Coal and iron are worked in the vicinity, and supply the raw material for very important ironworks, first established in the year 1827 by the Duc Decazes, which have since grown to such magnitude that the town ranks as the chief centre of the coal and iron industry in the south-west of France. Free schools and various benevolent institutions for the workpeople are in operation. A statue commemorates the founder. Population (1881), 6793; (1896), 7434, (comm.) 9634; (1901), 11,536.

**Decimal System.** See Weights and Measures.

**Dédéagatch,** a seaport of Turkey, capital of the province of the same name, about 10 miles north-west of the mouth of the Maritza. Till 1871 it was a mere cluster of fishermen's huts. A new town then began to spring up, settlers being attracted by the prospect of opening up a trade in the products of a vast forest of Valonia oaks which grew near. In 1873 it was made the chief town of a *Kaza*, to which it gave its name, and a *Kaimakam* was appointed to it. In 1884 it was raised in administrative rank from a *Kaza* to a *Sandjak*, and the governor became a *Mutessarif*. In 1889 the Greek Archbishopric of Enos was transferred to Dédéagatch. On the opening, early in 1896, of the Constantinople-Salonica Railway, which has a station here, a large proportion of the extensive transit trade which Enos, situated at the mouth of the Maritza, had acquired was immediately diverted to Dédéagatch, and an era of unprecedented prosperity began; but when the railway connecting Burgas on the Black Sea with the interior was opened, in 1898, it lost all it had won from Enos. The Valonia trade, however, has steadily developed, and is supplemented by the export of a certain amount of timber and some almonds. But until the open roadstead is converted into a well-sheltered harbour it will be impossible for this place to become the entrepôt which its position otherwise eminently qualifies it to be. It has no manufacturing industry of any kind. Its population numbers about 4000 souls, of whom 2500 are Greeks. Austria-Hungary, France, Great Britain, Greece, and Russia have consular representatives at Dédéagatch, and Bulgaria has an agent there. In digging out the foundations of their houses, the settlers found many ancient tombs. Probably these are relics, not of the necropolis of the ancient Zone, but of a *Téké* of Dervishes, of the Dédé sect, which was established shortly after the conquest, and whose occupants gave to the place its name—Dédéagatch.

**Dedham,** capital of Norfolk county, Massachusetts, U.S.A., with an area of 23 square miles of quite level country. There are three villages in the town, known as Dedham, East Dedham, and Oakdale. The town is traversed by the New York, New Haven, and Hartford Railway. The chief industry is the manufacture of woollen goods. Population (1880), 6233; (1890), 7123; (1900), 7457, of whom 2186 were foreign-born and 65 negroes.

**Deer.**—The classification of the family Cervidæ has been much altered since the article in *Ency. Brit.* vol. vii. was written. Deer are now arranged as follows:—First, the Reindeer (*Rangifer tarandus*), with several local races, distinguished from all other forms by the presence of antlers in both sexes. Second, the Elks (*Alces*), in which the antlers diverge at right angles to the middle line of the skull. Third, the typical Deer (*Cervus*), characterized by the antlers diverging obliquely to the middle line of the skull, and having a brow-tine. They include the typical, or Red Deer group, containing the Red Deer (*C. elaphus*), Hangul (*C. cashmirianus*), Shou (*C. affinis*), Duke of Bedford's Deer (*C. xanthopygus*), and the Wapiti (*C. canadensis*), of which a variety is found in Central Asia. Also the Sika group (sub-genus *Pseudaxis*), as represented by the Japanese Deer (*C. sica*) and Pekin Deer (*C. hortulorum*). The Fallow Deer (*C. dama*) represents a group by itself. This is followed by the Oriental Rusine group (*Rusa*), with 3-tined antlers, as represented by the numerous races of the Sambar (*C. unicolor*), the Rusa (*C. hippelaphus*), the Chital (*C. axis*), and many smaller forms. The Swamp-Deer (*C. duvauceli*) and Thamin (*C. eldi*) are well-known members of the last, or Rucervine group, which is likewise Oriental. The five species of Muntjac constitute the fourth genus (*Cervulus*) of the family; while the fifth is formed by the Tufted Deer (*Elaphodus*) of North China and Tibet. Then follows the hornless Chinese Water-Deer (*Hydrelaphus*), which is succeeded by the Roes (*Capreolus*). These latter have no brow-tine, and the same is the case with the much larger Père David's Deer (*Elaphurus davidianus*), now known only in captivity. Allied to the last are the numerous species of American Deer (*Mazama*), of which the common species (*M. americana*) represents one group (*Odocoileus*), the Marsh-Deer (*M. dichotoma*) a second (*Blastoceros*), the Guemals (*M. bisulca* and *M. antisiensis*) a third (*Xenelaphus*), and the Brockets a fourth. Lastly, we have the diminutive American Pudus (*Pudua*), and the Musk-Deer (*Moschus*), which forms a subfamily apart. (R. L*.)

**Deés** or **Dés,** a corporate town of Eastern Hungary, 48 miles north-north-east of Kolozvár, on the river Szamos. Population (1900), 9888. Among several ancient buildings the most noteworthy is the Gothic Calvinist church, constructed in 1450. There is a large distillery in the town.

**Defiance,** capital of Defiance county, Ohio, U.S.A., on the Maumee river, at the mouth of the Auglaize, at an altitude of 695 feet. It has two railways, the Baltimore and Ohio, and the Wabash, and it is the seat of Defiance College. Population (1880), 5907; (1890), 7694; (1900), 7579, of whom 960 were foreign-born and 39 negroes.

**Degas, Hilaire Germain Edgard** (1834——), French painter, was born in Paris, 19th July 1834. Entering in 1855 the École des Beaux Arts, he early developed independence of artistic outlook, studying under Lamothe. He first exhibited in the Salon of 1865, contributing a "War in the Middle Ages," a work executed in pastel. To this medium he was ever faithful, using it for some of his best work. In 1866 his "Steeplechase" revealed him as a painter of the racecourse and of all the most modern aspects of life and of Parisian society, treated in an extremely original manner. He subsequently exhibited in 1867 "Family Portraits," and in 1868 a portrait of a dancer in the "Ballet of *La Source*." In 1869 and 1870 he restricted himself to portraits; but thenceforward he abandoned the Salons and attached himself to the Impressionists. With Manet and Monet he took the lead of the new school at its first exhibition in 1874, and repeatedly contributed to these exhibitions (in 1876, 1878, 1879, and 1880). In 1868 he had shown his first study of a dancer, and in numerous pastels he proclaimed himself the painter of the ballet, representing its figurantes in every attitude, with more constant aim at truth than grace. Several of his works may be seen at the Luxembourg Gallery, to which they were bequeathed, among a collection of impressionist pictures, by M. Caillebotte. In 1880 Degas showed his powers of observation in a set of "Portraits of Criminals," and he attempted modelling in a

"Danseuse sur la Scène." By Degas.

*(In the Luxembourg.)*

"Dancer," in wax. He afterwards returned to his studies of the sporting world, exhibiting in December 1884 at the Petit Gallery two views of "Races" which had a great success, proving the increasing vogue of the artist among collectors. He is ranked with Manet as the leader of the "impressionist school." At the eighth Impressionist Exhibition, in 1886, Degas continued his realistic studies of modern life, showing drawings of the nude, of work-women, and of jockeys. Besides his pastels and his paintings of genre and portraits—among these, several likenesses of Manet—Degas also handled his favourite subjects in etching and in aquatint; and executed several lithographs of "Singers at Cafés-concert," of "Ballet-girls," and indeed of every possible subject of night-life and incidents behind the scenes. Degas is reputed not to have striven for official recognition; but his work is to be seen not only at the Luxembourg but in many of the great private collections in Paris, as in those of M. Camondo and M. Manzi, in England and America. In the Centenary Exhibition of 1900 he exhibited "The Interior of a Cotton-Broker's Office at New Orleans" (belonging to the Museum at Pau) and "The Rehearsal."

**Dehra,** a town of British India, headquarters of the Dehra Dun district. In 1881 the population was 18,959; in 1891 it was 25,684; the municipal income in 1897–98 was Rs.27,518; the death-rate in 1897 was 27·15 per thousand. It is the headquarters of the Trigonometrical Survey, and of the Forest Department, besides being a cantonment for a Gurkha regiment; it has an American Presbyterian mission.

**Dehra Dun,** a district of British India, in the Meerut division of the North-West Provinces. Its area is 1193 square miles. The population in 1881 was 144,070; in 1891 it was 168,135, giving an average density of 141 persons per square mile. In 1901 the population was 177,646, showing an increase of 6 per cent. The land revenue and rates were Rs.1,12,666, the incidence of assessment being R.0–5–9 per acre; the cultivated area in 1896–97 was 87,912 acres, of which 23,441 were irrigated; the number of police was 372; there were 22 vernacular schools, with 705 pupils; the death-rate in 1897 was 24·25 per thousand. A railway to Dehra from Hardwar, on the Oudh and Rohilkhand line (32 miles), was completed in 1900. Up to 1897–98 the capital outlay on the Dun canals was Rs.7,15,311; the net receipts in that year were Rs.68,151, showing a profit of 9·5 per cent. There are four printing-presses, issuing two English and one vernacular newspapers; and three breweries. Tea gardens cover an area of nearly 5000 acres.

**Deir,** or **Deir ez-Zor,** a town of Asiatic Turkey, on the right bank of the Euphrates, at an altitude of 806 feet. It is the capital of the Zor sanjak, which was formed in 1857, and includes Rás el-'Ain to the east, and Palmyra to the west of the river. The town is connected by a bridge with an island, whence there is a ferry to the left bank. The climate is healthy, but hot. Large numbers of sheep and camels are bred in the sanjak, and cereals are grown. Roads lead to Aleppo and Damascus, and, by Sinjar, to Mosul. The population of the sanjak is 100,000, chiefly nomads; of the town, 7000, including a few Christians and Jews.

**Dekalb,** a city of Dekalb county, Illinois, U.S.A., in the northern part of the state, at the intersection of two railways. Population (1890), 2579; (1900), 5904, of whom 1520 were foreign-born.

**Dekker, Edward Douwes** (1820–1887), the Dutch writer, commonly known as Multatuli, was born at Amsterdam on the 2nd of March 1820. His father, a ship's captain, intended his son for trade, but this humdrum prospect disgusted him, and in 1838 he went out to Java, and obtained a post in the Inland Revenue. He rose from one position to another, until, in 1851, he found himself assistant-resident at Amboyna, in the Moluccas. In 1857 he was transferred to Lebak, in the Bantam residency of Java. By this time, however, all the secrets of Dutch administration were known to him, and he had begun to protest against the abuses of the colonial system. In consequence he was threatened with dismissal from his office for his openness of speech, and, throwing up his appointment, he returned to Holland in a state of fierce indignation. He determined to expose in detail the scandals he had witnessed, and he began to do so in newspaper articles and pamphlets. Little notice, however, was taken of his protestations, until, in 1860, he published, under the pseudonym of "Multatuli," his romance entitled *Max Havelaar.* An attempt was made to ignore this brilliant and irregular book, but in vain; it was read all over Europe. The exposure of the abuse of free labour in the Dutch Indies was complete, although there were not wanting apologists who accused Dekker's terrible picture of being over-coloured. He was now fairly launched on literature, and he lost no time in publishing *Love Letters* (1861), which, in spite of their mild title, proved to be mordant satires of the most rancorous and unsparing kind. The literary merit of Multatuli's work was much contested; he received an unexpected and most valuable ally in Vosmaer. He continued to write much, and to faggot his miscellanies in uniform volumes called *Ideas,* of which seven appeared between 1862 and 1877. Douwes Dekker quitted Holland, shaking off her dust from his feet, and went to live at Wiesbaden. He now made several attempts to gain the stage, and one of his pieces, *The School for Princes,* 1875 (published in the fourth volume of *Ideas*), pleased himself so highly that he is said to have styled it the greatest drama ever written. It is a fine poem, written in blank verse, like an English tragedy, and not in Dutch Alexandrines; but it is undramatic, and has not held the boards. Douwes Dekker moved his residence to Nieder Ingelheim, on the Rhine, and there he died on the 19th of February 1887. Towards the end of his career he was the centre of a crowd of disciples and imitators, who did his reputation no service; he is now, again, in danger of being read too little. To understand his fame, it is necessary to remember the sensational way in which he broke into the dulness of Dutch literature forty years ago, like a flame out of the Far East. He was ardent, provocative, perhaps a little hysterical, but he made himself heard all over Europe. He brought an exceedingly severe indictment against the egotism and brutality of the administrators of Dutch India, and he framed it in a literary form which was brilliantly original. Not satisfied with this, he attacked, in a fury that was sometimes blind, everything that seemed to him falsely conventional in Dutch religion, government, society, and morals. He respected nothing, he left no institution untouched. Now that it is possible to look back upon Multatuli without passion, we see in him, not what Dutch enthusiasm saw,—"the second writer of Europe in the nineteenth century" (Victor Hugo being presumably the first),—but a great man who was a powerful and glowing author, yet hardly an artist, a reckless enthusiast, who was inspired by indignation and a burning sense of justice, who cared little for his means if only he could produce his effect. He is seen to his best and worst in *Max Havelaar*; his *Ideas,* hard, fantastic, and sardonic,

seldom offer any solid satisfaction to the foreign reader. But Multatuli deserves remembrance, if only on account of the unequalled effect his writing had in rousing Holland from the intellectual and moral lethargy in which she lay half a century ago. (E. G.)

**Delane, John Thaddeus** (1817–1879), editor of *The Times*, was born 11th October 1817, in London, being the second son of Mr W. F. A. Delane, a barrister who was employed by Mr Walter in *The Times* office. While still a boy he attracted Mr Walter's attention, and it was always intended that he should find work on the paper. He received a good general education at private schools and King's College, London, and also at Magdalen Hall, Oxford; and after taking his degree in 1839, he read for the Bar, being called in 1847. Meanwhile he had already begun work for *The Times* as a reporter; and in 1841, on the death of Mr Barnes, he succeeded him as editor, a post which he occupied for thirty-six years. He was not himself a writer, but he was the greatest newspaper editor of his time, and perhaps of any time. Though he went into society and had a position there such as no journalist had previously enjoyed, using his opportunities with a sure intuition for the way in which events would move, he had no liking for personal publicity, but was careful to preserve his impersonality as an editor, and to merge himself in the newspaper which he represented. His triumph was the triumph of *The Times*, which under his régime attained an influence which has never been surpassed. He was a man of many interests and great judgment; capable of long application and concentrated attention, with power to seize always on the main point at issue, and rapidly master the essential facts in the most complicated affair. His general policy was to keep the paper a national organ of opinion above party, but with a tendency to sympathize with the Liberal movements of the day. He admired Palmerston and respected Lord Aberdeen, and was of considerable use to both; and it was Lord Aberdeen himself who, in 1845, told him of the impending repeal of the Corn Laws, an incident round which many incorrect stories have gathered. The history, however, of the events during the thirteen administrations, between 1841 and 1877, in which *The Times*, and therefore Delane, played an important part cannot here be recapitulated. In 1877 his health gave way, and he retired from the editorship; and on 22nd November 1879 he died at Ascot. (H. CH.)

**De la Rue, Warren** (1815–1889), British astronomer and chemist, son of Thomas de la Rue, the founder of the large firm of stationers of that name in London, was born in Guernsey on 18th January 1815. Having completed his education in Paris, he entered his father's business, but in his leisure hours he devoted himself with success to chemical and electrical researches, and between 1836 and 1848 published several papers on these subjects. Towards the end of this period he was attracted to astronomy, and with the aid of a 13-inch reflecting telescope, the optical parts of which were made entirely by himself, he executed many drawings of the celestial bodies of singular beauty and fidelity. His name, however, will be chiefly remembered as one of the earliest and most successful pioneers in the application of the art of photography to astronomical research. In the year 1851 his attention was drawn to a daguerreotype of the moon by G. P. Bond, which was exhibited at the Great Exhibition of that year. Encouraged by this first attempt, and employing the more rapid wet-collodion process, he succeeded before long in obtaining exquisitely defined automatic pictures of the moon, which remained unsurpassed until the appearance of the Rutherfurd photographs in 1865. In 1854 he turned his attention to solar physics, and for the purpose of obtaining a daily photographic representation of the state of the solar surface he devised the photoheliograph. This instrument is described in his report to the British Association, "On Celestial Photography in England" (1859), and in his Bakerian Lecture (*Phil. Trans. Roy. Soc.* vol. clii. pp. 333–416). Regular work with this instrument was inaugurated at Kew by De la Rue in 1858, and was carried on there for fourteen years; since 1872 it has been continued at the Royal Observatory, Greenwich. The results obtained in the years 1862–1866 are discussed in two memoirs published by De la Rue, in conjunction with Professor Balfour Stewart and Mr B. Loewy, in the *Phil. Trans.* (vol. clix. pp. 1–110, and vol. clx. pp. 389–496), entitled "Researches on Solar Physics." In the year 1860 De la Rue took the photoheliograph to Spain for the purpose of photographing the total eclipse of the sun, which occurred on July the 18th of that year. This expedition formed the subject of the Bakerian Lecture already referred to. The photographs obtained on that occasion proved beyond doubt the solar character of the prominences, or red flames, seen around the limb of the moon during a solar eclipse. In 1873 De la Rue gave up active work in astronomy, and presented most of his astronomical instruments to the University Observatory, Oxford. Subsequently, in the year 1887, he provided the same observatory with a 13-inch refractor to enable it to take part in the International Photographic Survey of the Heavens. In conjunction with Dr Hugo Müller, he published several papers of a chemical character between the years 1856 and 1862. He was twice President of the Chemical Society, and also of the Royal Astronomical Society (1864–1866). In 1862 he received the gold medal of the latter society, and in 1864 a Royal medal from the Royal Society, for his observations on the total eclipse of the sun in 1860, and for his improvements in astronomical photography. He died on 19th April 1889. (A. A. R*.)

**Delaware.**—One of the Middle Atlantic States of the American Union, and next to Rhode Island the smallest in extent, Delaware is situated on the Atlantic seaboard, and forms part of the peninsula between the Chesapeake and Delaware Bays. Its total land surface is approximately 1960 square miles. The population in 1870 was 125,015, of whom 102,221 were white and 22,794 coloured; in 1880 it was 146,608, of whom 120,160 were white, 26,442 coloured, 5 civilized Indians, and 1 Chinese. In 1890 it was 168,493, of whom 140,066 were white, 28,386 coloured, 37 Chinese, and 4 civilized Indians. In 1900 the population was 184,735, of whom 153,997 were white, 30,677 negroes, 51 Chinese, 1 Japanese, and 9 Indians. Out of 54,018 males 21 years of age and over, 7538 were illiterate (unable to write), of whom 3945 were white and 3593 coloured. Of the total population 94,158 (51 per cent.) were males, and 90,557 (49 per cent.) females; 170,925 (92·5 per cent.) were native-born, and 13,810 (7·5 per cent.) foreign-born. The increase in population from 1890 to 1900 was 9·6 per cent., and the number of inhabitants per square mile in 1900 was 94·2. There were 35 incorporated cities and towns. The largest city was Wilmington, with 76,508 inhabitants. The city next in size, Newcastle, had a population of but 3380, while the largest town, Dover, the State capital, had 3329. In Indian River Hundred, Sussex county, there lives a race of persons, nearly white, called "Indians" or "Moors," whose origin is unknown, although local tradition says they are the descendants of some Moorish sailors who were cast ashore years ago in a shipwreck. They do not associate with

persons of negro descent; and they maintain separate churches and schools, the latter receiving State aid. Delaware is an agricultural and manufacturing State. Much of it is in a high state of cultivation. Besides wheat, maize, and other grain, peaches are grown in immense quantities and sent over the country. Strawberries, raspberries, and other small fruits are raised for transportation. Increased attention has lately been given to dairy products. The canning of fruits, vegetables, meats and poultry, is carried on extensively. The kaolin mines were among those first worked in the United States, the product in 1899 being 10,500 tons, valued at $91,500. The forests, which afforded excellent timber, including white oak for the building of ships, have been greatly reduced by constant cutting. In the northern part of the State there are numerous and important manufactories. Wilmington and its suburbs have large machine shops, whose products, including marine engines and boilers and paper and pulp machines, are justly renowned; cotton, cotton-finishing, paper, morocco, patent leather, vulcanized fibre, car-wheel, carriage, and silk factories; rolling-mills and bridge works. Cars, for steam and street railways, are manufactured on a large scale. Upwards of 400 iron steamships have been built in Wilmington, exceeding in number and in aggregate tonnage those constructed in any other American city. The flour-mills on the Brandywine, founded in 1762, are famous, and the Dupont Gunpowder Works, 6 miles from Wilmington, are the oldest and largest in the country. There is a petroleum refinery at Marcus Hook.

According to the census of 1900, the number of manufacturing establishments in the State (excluding 169 having an annual product of less than $500 each) was 1417, in which was invested a total capital (including land, buildings, machinery, tools, &c., but not including capital stock) of $41,203,239. There were 1327 salaried employées receiving salaries amounting to $1,422,831, and an average number of 22,203 wage-earners receiving $9,263,661 in wages. The cost of materials used, including mill supplies, freight, fuel, &c., was $26,652,601, and the miscellaneous expenses (including rent, taxes, &c., but not including interest on capital invested) $2,158,350. The added values of the products in the different establishments amounted to $45,387,630. If from this gross value be deducted, in order to avoid duplication, the value ($15,849,388) of materials purchased in a partly manufactured form—where the finished product of one industry is used later as the raw material for another—the net value is found to be $29,538,242. If the steel and rolling-mills, car shops, foundry and machine shops, and shipbuilding be grouped as the iron and steel industry, there were in this industry fifty-three establishments having a capital of $14,929,935, employing 8536 wage-earners, paying $4,265,670 as wages, and having a gross product of $13,953,379. The leather industry ranks next in importance, with twenty establishments, a capital of $5,178,804, 2457 wage-earners receiving $1,044,903, and gross product of $9,400,504.

The Delaware and Chesapeake Canal connects the Delaware and Chesapeake Bays, and affords water transit for produce between Philadelphia and Baltimore. The Philadelphia, Wilmington, and Baltimore Railroad, and the Baltimore and Philadelphia Railroad run through the northern part of the State; the Wilmington and Northern Railroad communicates with the Pennsylvania coal region; the Delaware Railroad runs through the whole length of the State below Wilmington, connecting with various railways that reach either the Atlantic Ocean or the Chesapeake Bay; while another line, running directly across the lower part of the State, connects, at Queenstown, Maryland, with steamers for Baltimore.

The financial condition of the State is excellent, the assets, in bonds, railway mortgages, and bank stocks, exceeding the liabilities. Besides the income from assets, the State revenues are derived from taxes on licences, on commissions to public officers, on railway and banking companies, and to a slight extent from taxes on collateral inheritances, and on investments, as bonds, mortgages, notes and stocks, the investment tax yielding in 1899 only $1,311.35. There are county taxes, on land and live-stock, for the care of the roads and the poor; local taxes, levied on the rental value of land and on live-stock, towards the support of the public schools; town taxes, and, in same places, ditch taxes.

The vital statistics of the State are of little value, not having been systematically kept. A State Board of Health was organized in 1879, and there are now local boards in various towns. There is in each county a jail and an almshouse. Under recent legislation there is to be established in Newcastle county a workhouse, where persons under sentence must labour for eight hours each secular day, pay being allowed for overwork, and credit given, by reduction of sentence, for good behaviour. There is a State hospital for the insane. A certain number of persons are maintained out of the State School fund at outside institutions, such as the Pennsylvania Institution for the Deaf and Dumb, and the Pennsylvania Training School for Feeble-Minded Children. There are various private charities, particularly in the city of Wilmington.

Education exhibits progress. Delaware College, at Newark, with the support of Federal grants, steadily increases in efficiency. The maintenance of a system of public schools is rendered compulsory by the State Constitution. The State School fund, ranging from about $130,000 to $140,000 a year, is apportioned among the school districts, and is used exclusively for teachers' salaries and free text-books. In the apportionment no discrimination is allowed on account of race or colour; but separate schools for white and coloured children must be provided, and there is a State college for coloured students. Besides the State Board of Education, there is in each county a School Commission and a Superintendent of Public Schools, and in each district a School Committee chosen by the voters of the district, with power to levy taxes. At school elections women as well as men may be qualified to vote.

The Constitution now in force was framed in 1897, superseding the Constitution of 1831. Following the precedent recently set elsewhere, it was published and put into operation by authority of a resolution of the Constitutional Convention, without submission to the people. In the General Assembly the number of Representatives is raised from 21 to 35, and of Senators from 9 to 17, equal county representation being done away with.

The State is divided into 35 representative districts, Newcastle county having 15, and Kent and Sussex each 10; and 17 senatorial districts, Newcastle having 7, and Kent and Sussex each 5. Of the 15 Newcastle Representatives, Wilmington has 5; of the 7 Senators, 2. The sessions of the General Assembly, held at Dover, the State capital, are still biennial. The members receive an allowance for each day of the session not exceeding sixty, after which they get no compensation. At a special session the daily allowance is limited to thirty days. Legislative divorces are prohibited. The Governor's appointments to office must, except in certain cases, be confirmed by the Senate. He has a suspensory veto on legislation. Certain State officers, including the Attorney-General, and various county officers, formerly appointed by the Governor, are now elected. The judges are still appointed, but only for terms of twelve years. All persons coming of age, or becoming citizens of the United States, after 1st January 1900, must, in order to vote, be able to read the State Constitution in English and write their names. The payment of a poll-tax as a prerequisite to voting is abolished, and all eligible persons are registered on payment of a fee of one dollar. Persons charged with bribery at elections are triable by the court on information and without a jury. A Board of Pardons, consisting of the Chancellor and certain administrative officers, is created, and no reprieve for more than six months, or commutation of sentence, or pardon, can be granted by the Governor unless on the written recommendation of a majority of this Board. There is also established a State Board of Agriculture.

The Judicial power of the State is vested in a Supreme Court, a Superior Court, a Court of Chancery, an Orphans' Court, a Court of Oyer and Terminer, a Register's Court, and Justices of the Peace. There are six State judges, namely, a Chancellor, a Chief Justice, and four Associate judges. The Chancellor, Chief Justice, and one of the Associates may be appointed from and reside in any part of the State; the other three Associates may be appointed from any part of the State, but must reside one in each county. The five law judges compose the Superior Court, Court of General Sessions, and Court of Oyer and Terminer, but not

more than three of them can sit together in any one of those courts, though three must do so whenever practicable. Two constitute a quorum, save in the Court of Oyer and Terminer, where three are required. The Supreme Court consists, on error or appeal from a law court, of the Chancellor, who presides, and such of the five law judges as did not sit below; on appeal from the Court of Chancery, of the five law judges, three of whom constitute a quorum.

In *politics*, since the close of the Civil War in 1865, the State has generally been Democratic. But, in 1889, a Republican was elected to the United States Senate; and candidates of the same party were, in 1894, 1898, and 1900, chosen to the National House of Representatives, and, in 1894 and 1900, to the Governorship. In 1895, 1899, and 1901, the Legislature, being then Republican, was, because of a division in the party as to candidates, unable to elect a United States Senator, so that the State had, from 4th March 1895 till 1897, and from 4th March 1899 till 4th March 1901 only one United States Senator, and none at the special session of the Senate in March 1900. In 1896 and 1900, Mr M'Kinley, the Republican candidate for the Presidency, partly because of the attitude of the Gold Democrats, carried the State by large majorities. General Grant obtained, as the Republican candidate in 1872, a small majority. (J. B. M*.)

**Delaware,** capital of Delaware county, Ohio, U.S.A., on the Olentangy river, at an altitude of 902 feet. It has three railways, the Cleveland, Cincinnati, Chicago, and St Louis, the Columbus, Sandusky and Hocking, and the Hocking Valley. The Ohio Wesleyan University, located here, had, in 1899, 53 professors and instructors, and 1055 students, one-third of whom were women. Its property was valued at over $1,300,000, and its income was $62,000. Population (1880), 6894; (1890), 8224; (1900), 7940, of whom 572 were foreign-born and 432 negroes.

**Delaware River,** a river of the eastern United States, rises in the Catskill Mountains, in south-eastern New York, and flows south-west to the north-east corner of Pennsylvania; thence, with a south-east course, it forms the boundary between New York and Pennyslvania, and farther down, with a course alternating between south-east and south-west, it forms the boundary between New Jersey on the east and Pennsylvania and Delaware on the west. It has no well-defined mouth, but gradually widens into Delaware Bay. It is navigable to Trenton, where are falls, a distance from the capes of the Delaware of 128 miles. Its entire length from its head to the capes at the entrance to Delaware Bay is upwards of 400 miles and its drainage basin comprises 12,012 square miles. In its upper course, after leaving the Catskills, it flows alternately through the valleys between the Appalachian ridges and across these ridges through water-gaps. The most picturesque and best known of these is Delaware Water-Gap. The falls at Trenton, which have been utilised for power, are produced by the passage of the river over a fault-line from hard granite rocks to soft Tertiary beds.

**Delbrück, Martin Friedrich Rudolf,** Prussian statesman (1817-——), was born at Berlin on 16th April 1817. On completing his legal studies he entered the service of the State in 1837; and after holding a series of minor posts, was transferred in 1844 to the Ministry of Commerce, which was to be the sphere of his real life's work. Both Germany and Austria had realized the influence of commercial upon political union. Delbrück in 1851 induced Hanover, Oldenburg, and Schaumburg-Lippe to join the Zollverein; and the southern States, which had agreed to admit Austria to the union, found themselves forced in 1853 to renew the old union, from which Austria was excluded. Delbrück now began, with the support of Bismarck, to apply the principles of Free Trade to Prussian fiscal policy. In 1862 he concluded an important commercial treaty with France, which he succeeded in inducing the southern States to accept. After the Prussian victories of 1866, a Zollbundesrath or Federal Council was constituted, in which Delbrück, who became the first President of the Bundeskanzleramt or Federal Chancellery (1867), represented Bismarck in political as well as commercial questions. In 1868 he became a Prussian Minister without portfolio. In October 1870, when the political union of Germany under Prussian headship became a practical question, Delbrück was chosen to go on a mission to the South German States, and contributed greatly to the agreements concluded at Versailles in November. In 1871 he became President of the newly constituted Reichskanzleramt. Delbrück now, however, began to feel himself uneasy under Bismarck's leanings towards Protection and State control. On the introduction of Bismarck's plan for the acquisition of the railways by the State, Delbrück resigned office, nominally on the ground of ill-health (1st June 1876). In 1879 he opposed in the Reichstag the new protectionist tariff, and on the failure of his efforts retired definitely from public life.

**Delcassé, Théophile** (1852-——), French statesman, was born at Pamiers, in the department of Ariège, on 1st March 1852. He wrote articles on foreign affairs for the *République Française* and *Paris*, and in 1888 was elected Conseiller Général of his native department, standing as "un disciple fidèle de Gambetta." In the following year he entered the Chamber as deputy for Foix. He was appointed Under Secretary for the Colonies in the second Ribot Cabinet (January to April 1893), and retained his post in the Dupuy Cabinet till its fall in December 1893. It was largely owing to his efforts that the French Colonial Office was made a separate department with a Minister at its head, and to this office he was appointed in the second Dupuy Cabinet (May 1894 to January 1895). He gave a great impetus to French colonial enterprise, especially in West Africa, where he organized the newly acquired colony of Dahomey, and despatched the Liotard mission to the Upper Ubangi. While in opposition, he devoted special attention to naval affairs, and in speeches that attracted much notice declared that the function of the French navy was to secure and develop colonial enterprise, deprecated all attempts to rival the British fleet, and advocated the construction of commerce-destroyers as France's best reply to England. On the formation of the second Brisson Cabinet in June 1898 he succeeded M. Hanotaux at the Foreign Office, and retained that post under the subsequent premierships of MM. Dupuy and Waldeck-Rousseau. In 1898 he had to deal with the delicate situation caused by Captain Marchand's occupation of Fashoda, for which, as he admitted in a speech in the Chamber on 23rd January 1899, he accepted full responsibility, since it arose directly out of the Liotard expedition, which he had himself organized while Minister for the Colonies; and in March 1899 he concluded an agreement with Great Britain by which the difficulty was finally adjusted, and France consolidated her vast colonial empire in North-West Africa. In the same year he acted as mediator between the United States and Spain, and brought the peace negotiations to a successful conclusion. He introduced greater cordiality into the relations of France with Italy: at the same time he adhered firmly to the alliance with Russia, and in August 1899 made a visit to St Petersburg, which he repeated in April 1901. In June 1900 he concluded an important agreement with Spain, fixing the long-disputed boundaries of the French and Spanish possessions in West Africa.

**Delft,** a town in the province of South Holland, Netherlands, 10 miles north-west of Rotterdam by rail. Formerly it rivalled Rotterdam in the importance of its shipping and commerce, but it is now only the market for the butter and cheese of the fertile district around. There is still

considerable industry in earthenware ("New Delft"), gun-construction, distilling, and the manufacture of salad oil and oil-cakes. The "Phœnix," or old clubhouse of the students, which was burned down in 1872, has been replaced by a handsome erection in Renaissance style. A bronze statue of Hugo Grotius was raised in 1886. The population in 1900 was 31,582.

**Delhi,** or DILLI, a city of British India, the former capital of the Mughal Empire, now giving its name to a district and a division in the Punjab. It is situated on the right bank of the river Jumna, 954 miles from Calcutta by rail. In 1881 it had a population of 173,393, and in 1891 of 192,579. In 1901 the population was 208,385, showing a continuous increase. The municipal income in 1897–98 was Rs.4,57,182; the death-rate in 1897 was 34 per thousand. Delhi, as the centre of the railway system of Northern India, is now regaining much of the importance it lost at the time of the Mutiny. It is the terminus of three main lines—the East Indian, the North-Western, and the Rajputana; while the Delhi-Umballa-Kalka and the Northern Punjab companies also have stations here. The principal manufactures are gold and silver filigree-work and embroidery, jewellery, muslins, shawls, glazed pottery, and wood-carving. Since 1890 three cotton mills have been established, with 351 looms and 47,000 spindles, employing 1800 hands. There are also three flour-mills, several iron foundries, and a brush factory. A filtered water supply and sewerage works have been provided by the municipality out of a loan of Rs.8,00,000, and a further loan of Rs.1,80,000 for improving the water supply is proposed. The institutions include St Stephen's College, which teaches up to the M.A. degree; five high schools; Government normal school; native school of medicine subsidized by the municipality; S.P.G., Roman Catholic, and Baptist missions; sixty-four printing-presses, issuing twenty-one newspapers and periodicals; institute and reading room; Mahommedans and Hindu religious associations.

The DISTRICT OF DELHI has an area of 1290 square miles. The population in 1881 was 643,515 and in 1891 was 638,689, being the only case in the Punjab of a decrease; the average density was 495 persons per square mile. In 1901 the population was 688,979, showing an increase of 8 per cent. The land revenue and rates were Rs.8,90,644, the incidence of assessment being R.1–0–8 per acre; the cultivated area was 432,209 acres, of which 178,782 were irrigated, including 68,072 from Government canals; the number of police was 1031; the number of schools in 1897–98 was 237, attended by 8192 boys, being 13·8 per cent. of the boys of school-going age; the death-rate in 1897 was 33·34 per thousand. There are four factories for ginning and pressing cotton. Its northern portion is traversed by the Delhi-Umballa-Kalka Railway, and crossed by the Rajputana and Southern Punjab lines; total length, 74 miles. A new line, on the East Indian system, is now (1891) being constructed from Delhi southward to Agra through Muttra.

The DIVISION OF DELHI stretches from Simla to Rajputana, and is much broken up by native states. It comprises the seven districts of Hissar, Rohtak, Gurgaon, Delhi, Karnal, Umballa, and Simla. Its total area is 15,530 square miles, and in 1891 the population was 3,435,886.

**Delibes, Clément Philibert Léo** (1836–1891), French composer, was born at Saint Germain du Val on February 21, 1836. He studied at the Paris Conservatoire under Adolphe Adam, through whose influence he became accompanist at the Théâtre Lyrique. Towards the same period he began writing for the theatre, and during several years he produced a number of operettas. *Alger*, a cantata from his pen, was heard at the Opera in 1865. Having become second chorus-master at the Grand Opera, he wrote the music of a ballet entitled *La Source* for this theatre, in collaboration with Minkous, a Russian composer. *La Source* was produced with great success in 1866. The composer returned to the operetta style with *Malbrouk s'en va-t-en guerre*,—written in collaboration with Georges Bizet, Emile Jonas, and Legouix, and given at the Théâtre de l'Athénée in 1867. Two years later came *L'Ecossais de Chatou*, a one-act piece, and *La Cour du Roi Pétaud*, a three-act opera-bouffe. The ballet *Coppélia* was produced at the Grand Opera on 25th May 1870 with enormous success. Delibes's first important dramatic work was *Le Roi l'a dit*, a charming "opéra comique," heard for the first time on 24th May 1873 at the Opéra Comique Theatre. Three years later, on 14th June 1876, *Sylvia*, a ballet in three acts, one of the composer's most delightful works, was produced at the Grand Opera. This was followed by *Jean de Nivelle*, a three-act opera brought out at the Opéra Comique on 8th March 1880, and *Lakmé*, in three acts produced at the same theatre on 14th April 1883, which has remained his most popular opera. The composer died in Paris on the 17th January 1891, leaving *Kassya*, a four-act opera, in an unfinished state. This work was completed and scored by Massenet, and produced at the Opéra Comique Theatre on 24th March 1893. Léo Delibes was a typically French composer. His music is light, graceful, and refined. He excelled in ballet music, and *Sylvia* may well be considered a masterpiece of the *genre*. His operas are constructed on a conventional pattern. The harmonic texture, however, is modern, and the melodic invention abundant, while the orchestral treatment is invariably excellent.

(A. HE.)

**Delisle, Léopold Victor** (1826– ——), French historian and head of the Bibliothèque Nationale et Paris, was born at Valognes (Manche) on 24th October 1826. In 1847 he became a student at the École des Chartes, where his career was remarkably brilliant. In 1832 he was appointed an assistant in the Manuscript Department of the Bibliothèque Nationale, and after being for some time conservator of that department, succeeded M. Taschereau as head of the entire establishment in 1874. He produced many valuable official reports, and a still greater amount of memoirs and monographs on points connected with palæography, and the study of history and archæology. Among his services was the acquisition for France of a portion of the Ashburnham manuscripts, including many that, before M. Delisle's time, had been purloined from the Bibliothèque Nationale. In 1897 he commenced the publication of what is intended to be a nearly complete printed catalogue of the books in the Bibliothèque—a great enterprise destined to occupy many years in its completion.

**Delius, Nicolaus** (1813–1888), German philologist and Shakespearean scholar, was born at Bremen on 19th October 1813. He was educated at Bonn and Berlin, and took his Doctor's degree in 1838. After travelling for some time in England, France, and Germany, he returned to Bonn in 1846. In 1855 he was appointed Professor of Sanscrit, Provençal, and English Literature at Bonn University, a post he held until his death, which took place at Bonn, 18th November 1888. His greatest literary achievement was his scholarly edition of Shakespeare (1854–61). He also edited Wace's *St Nicholas* (1850) and a volume of Provençal songs (1853), and published a *Shakspere-Lexikon* (1852). His original works include: *Ueber das englische Theaterwesen zu Shakspere's Zeit* (1853), *Gedichte* (1853), *Der Sardinische Dialekt des*

*dreizehnten Jahrhunderts* (1868), and *Abhandlungen zu Shakspere* (2 series, 1878 and 1888). As a critic of Shakespeare's text he stands in the first rank. (R. F. S.)

**Delmenhorst,** a town of Germany, grand duchy of Oldenburg, 8 miles by rail west from Bremen, on the river Delme, was protected by a strong castle from 1247 to 1679, when it was destroyed by the French. Carries on cork-cutting, jute spinning and weaving, brewing, iron-founding, and making of boxes. Population (1885), 3842; (1900), 16,569.

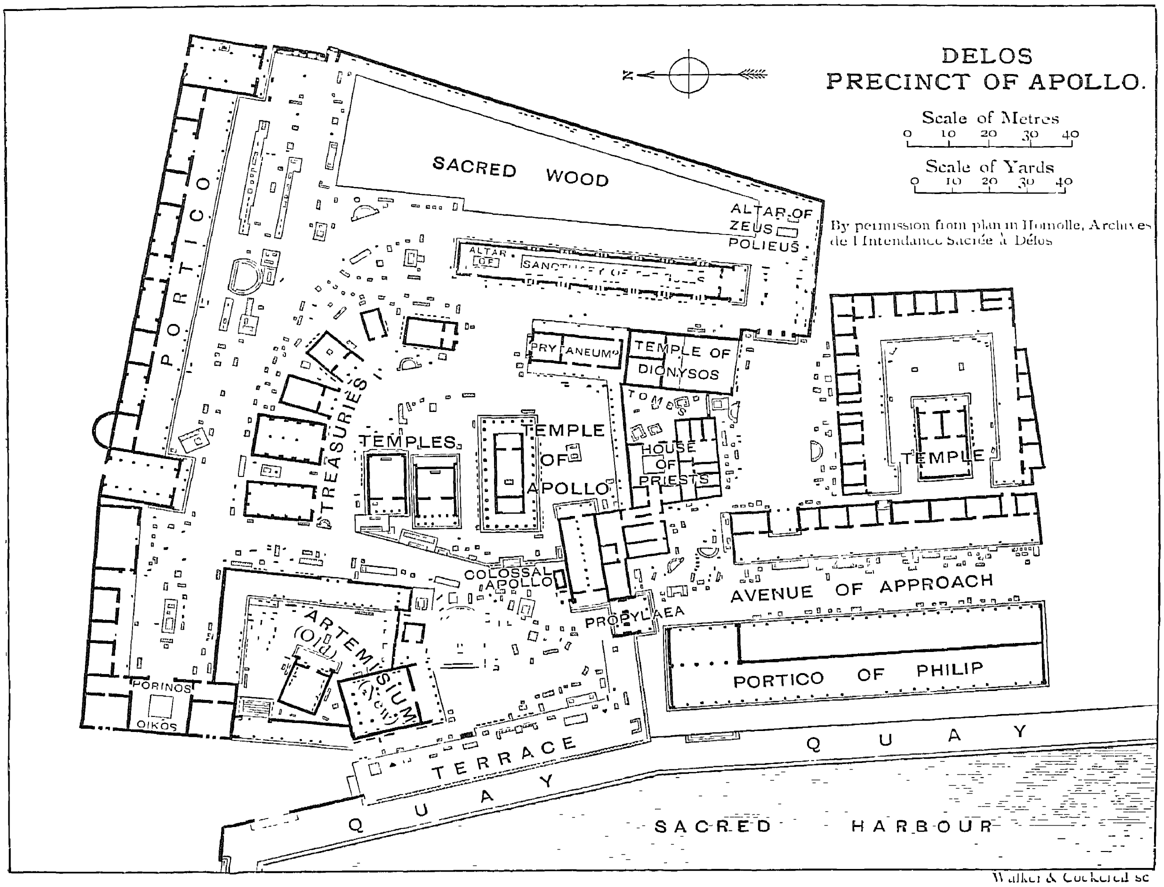
**De Long, George W.** (1844–1881), American explorer, was born in New York City on 22nd August 1844. He graduated at the U.S. Naval Academy in 1865, and spent the next fourteen years in the service in various parts of the world. In 1873 he sailed on the *Juniata* expedition in search of the Arctic exploring steamer *Polaris*, and was detailed to the command of the launch which was sent out by the *Juniata* from Upernivik, Greenland. On his return to New York the same year he proposed to Mr James Gordon Bennett, of the *New York Herald*, that the latter should fit out a Polar expedition, but it was not until 1879 that final arrangements were made. The *Pandora*, a private yacht which had been previously used in a number of Arctic expeditions, was purchased and rechristened the *Jeanette*, and strengthened and fitted out for the voyage. By Act of Congress the expedition was placed under the authority of the Secretary of the U.S. Navy, although all the expenses were borne by Mr Bennett. On 8th July 1879 the *Jeanette*, with 33 men on board, set sail from San Francisco for Siberian waters. On 5th September 1879 the vessel was enclosed in the ice-pack, and after a long drift was finally crushed by the ice on the 12th of June 1881 in 77° 15′ N. lat. and 155° E. long. The members of the expedition journeyed by sledge and boat 150 miles to the New Siberian Islands, and thence set out by boat in three parties for the mainland. The crew of one boat was lost in a gale; that of another, under the command of Chief-Engineer George W. Melville, reached a village on the Lena. The third party, under the command of De Long, succeeded in landing at the mouth of the Lena, and pushed forward up the river by land. All of De Long's party perished except two who had been sent forward to seek relief. The dead bodies and the records of the expedition were found in the following March by Melville, only 25 miles distant from a Siberian settlement. De Long was the last survivor. His journal, in which he made regular entries up to the day on which he died, has been edited by his wife and published under the title *Voyage of the "Jeanette."* An account of the search for De Long and his comrades was also published by G. W. Melville in his book entitled *In the Lena Delta.*

**Delos.**—Excavations have been made by the French School at Athens upon the island of Delos since 1877, chiefly by M. Th. Homolle. They have proceeded slowly but systematically, and the method adopted, though scientific and economical, has left the site in some apparent confusion, the débris being heaped up into piles or thrown into already excavated portions, instead of being removed bodily as at Olympia and at Delphi. The complete plan of the sacred precinct of Apollo has been recovered, as well as those of a considerable portion of the commercial quarter of Hellenistic and Roman times, of the theatre, of the temples of the foreign gods, of the temples on the top of Mount Cynthus, and of several very interesting private houses. Numerous works of sculpture of all periods have been found, and also a very extensive series of inscriptions, some of them throwing much light upon the subject of temple administration in Greece.

The most convenient place for landing is protected by an ancient mole; it faces the channel between Delos and Rheneia, and is about opposite the most northerly of the two little islands now called Ῥευματιάρι. From this side the sacred precinct of Apollo is approached by an avenue flanked by porticoes, that upon the seaside bearing the name of Philip V. of Macedon, who dedicated it about 200 B.C. This avenue must have formed the usual approach for sacred embassies and processions; but it is probable that the space to the south was not convenient for marshalling them, since Nicias, on the occasion of his famous embassy, built a bridge from the island of Hecate (the Greater Rhevmatiari) to Delos, in order that the imposing Athenian procession might not miss its full effect. Facing the avenue were the propylæa that formed the chief entrance of the precinct of Apollo. They consisted of a gate faced on the outside with a projecting portico of four columns, on the inside with two columns *in antis.* Through this one entered a large open space, filled with votive offerings and containing a large exedra. The sacred road continued its course from the north-east corner of this open space, with the precinct of Artemis on its west side, and, on its east side, a terrace on which stood three temples. The southernmost of these was the temple of Apollo, but only its back was visible from this side. Though there is no evidence to show to whom the other two were dedicated, the fact that they faced west seems to imply that they were either dedicated to heroes or minor deities, or that they were treasuries. Beyond them a road branches to the right, sweeping round in a broad curve to the space in front of the temple of Apollo. The outer side of this curve is bounded by a row of treasuries, similar to those found at Delos and Olympia, and serving to house the more costly offerings of various islands or cities. The space to the east and south of the temple of Apollo could also be approached directly from the propylæa of entrance, by turning to the right through a passage-like building with a porch at either end. Just to the north of this may be seen the basis of the colossal statue of Apollo dedicated by the Naxians, with its well-known archaic inscription; two large fragments of the statue itself may still be seen a little farther to the north.

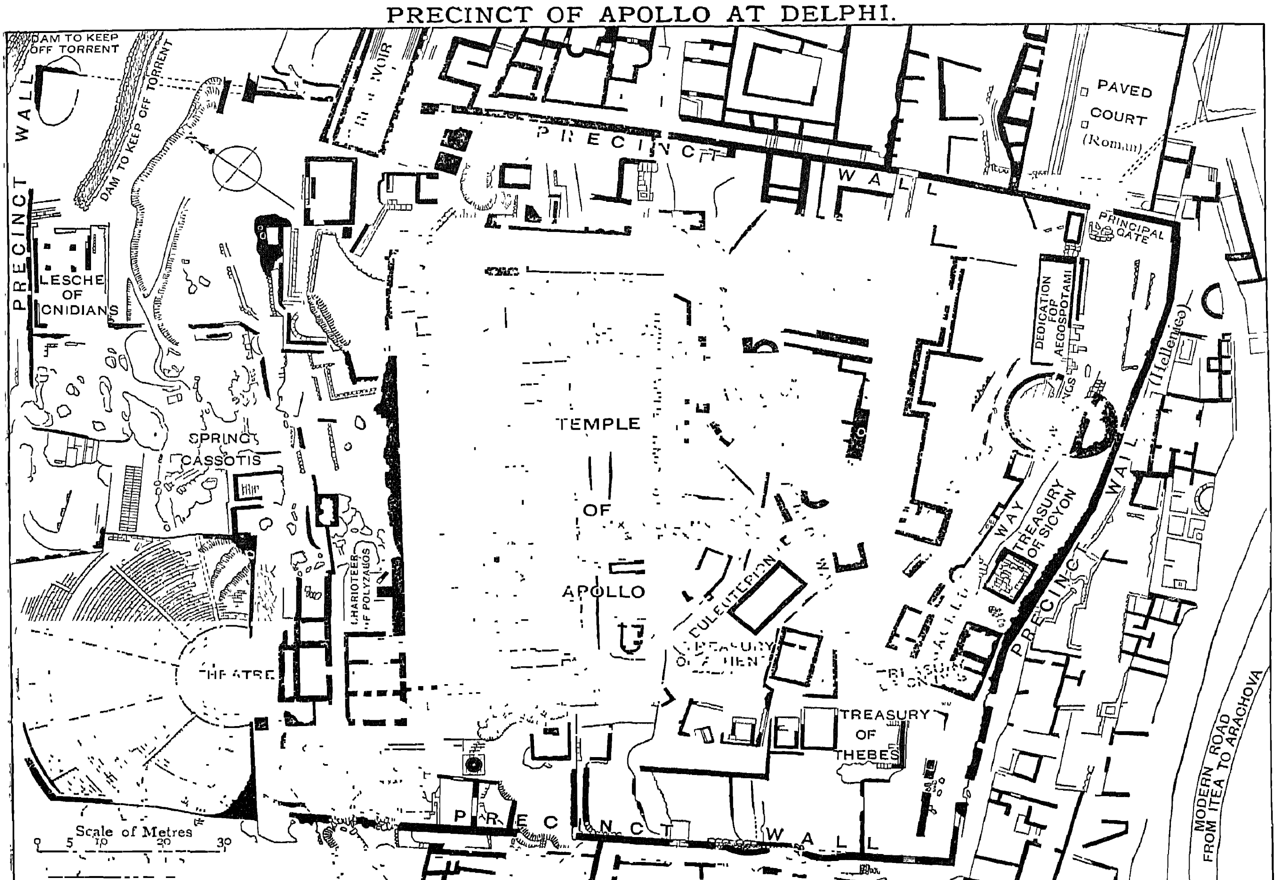
The temple of Apollo forms the centre of the whole precinct, which it dominates by the height of its steps as well as of the terrace already mentioned; its position must have been more commanding in ancient times than it is now that heaps of earth and débris cover so much of the level. The temple was of Doric style, with six columns at the front and back and thirteen at the sides; it was built early in the 4th century B.C.; little if any traces have been found of the earlier building which it superseded. Its sculptural decoration appears to have been but scanty; the metopes were plain. The groups which ornamented, as acroteria, the two gables of the temple have been in part recovered, and may now be seen in the National Museum at Athens; at the one end was Boreas carrying off Orithyia, at the other Eos and Cephalus, the centre in each case being occupied by the winged figure that stood out against the sky—a variation on the winged Victories that often occupy the same position on temples.

To the east of the space in front of the temple was an oblong building of two chambers, with a colonnade on each side but not in front; this may have been the Prytaneum or some other official building; beyond it is the most interesting and characteristic of all the monuments of Delphi. This is a long narrow hall, running from north to south, and entered by a portico at its south end. At the north end was the famous altar, built out of the horns of the victims, which was reckoned among the seven wonders of the world. The rest of the room is



Walker & Cockerell sc

PRECINCT OF APOLLO AT DELPHI.



Walker & Cockerell sc.

taken up by a paved space, surrounded by a narrow gangway; and on this it is supposed that the famous γέρανος or stork-dance took place. The most remarkable architectural feature of the building is the partition that separated the altar from this long gallery; it consists of two columns between *antæ*, with capitals of a very peculiar form, consisting of the fore parts of bulls set back to back; from these the whole building is sometimes called the sanctuary of the bulls. Beyond it, on the east, was a sacred wood filling the space up to the wall of the precinct; and at the south end of this was a small open space with the altar of Zeus Polieus.

At the north of the precinct was a broad road, flanked with votive offerings and exedræ, and along the boundary were porticoes and chambers intended for the reception of the θεωρίαι or sacred embassies; there are two entrances on this side, each of them through extensive propylæa.

At the north-west corner of the precinct is a building of limestone, the πώρινος οἶκος often mentioned in the inventories of the treasures of the Delian shrine. South of it is the precinct of Artemis, containing within it the old temple of the goddess; her more recent temple was to the south of her precinct, opening not into it but into the open space entered through the southern propylæa of the precinct of Apollo. The older temple is mentioned in some of the inventories as "the temple in which were the seven statues"; and close beside it was found a series of archaic draped female statues, which was the most important of its kind until the discovery of the finer and better preserved set from the Athenian Acropolis.

Within the precinct there were found many statues and other works of art, and a very large number of inscriptions, some of them giving inventories of the votive offerings and accounts of the administration of the temple and its property. The latter are of considerable interest, and give full information as to the sources of the revenue and its financial administration.

Outside the precinct of Apollo, on the south, was an open place; between this and the precinct was a house for the priests, and within it, in a kind of court, a set of small structures that may perhaps be identified as the tombs of the Hyperborean maidens. Just to the east was the temple of Dionysus, which is of peculiar plan, and faces the open place; on the other side of it is a large rectangular court, surrounded by colonnades and chambers which served as offices, the whole forming a sort of commercial exchange; in the middle of it was a temple dedicated to Aphrodite and Hermes.

To the north of the precinct of Apollo, between it and the sacred lake, there are very extensive ruins of the commercial town of Delos; these have been only partially cleared, but have yielded a good many inscriptions and other antiquities. The most extensive building is a very large court surrounded by chambers, a sort of club or exchange. Beyond this, on the way to the east coast, are the remains of the new and the old palæstra, also partially excavated.

The shore of the channel facing Rhenea is lined with docks and warehouses, and behind them, as well as elsewhere in the island, there have been found several private houses of the 2nd or 3rd century B.C. Each of these consists of a single court surrounded by columns and often paved with mosaic; various chambers open out of the court, including usually one of large proportions, the ἀνδρών or dining-room for guests.

The theatre, which is set in the lower slope of Mount Cynthus, has the wings of the auditorium supported by massive substructures. The most interesting feature is the *scena*, which is unique in plan; it consisted of an oblong building of two storeys, surrounded on all sides by a low portico or terrace reaching to the level of the first floor. This was supported by pillars, set closer together along the front than at the sides and back. An inscription found in the theatre showed that this portico, or at least the front portion of it, was called the proscenium or logeum, two terms of which the identity was previously disputed.

On the summit of Mount Cynthus, above the primitive cave-temple which has always been visible, there have been found the remains of a small precinct dedicated to Zeus Cynthius and Athena Cynthia. Some way down the slope of the hill, between the cave-temple and the ravine of the Inopus, is a terrace with the temples of the foreign gods, Isis and Serapis, and a small odeum.

Numerous articles in the *Bulletin de Correspondence Hellénique* record the various discoveries at Delos as they were made. See also Th. Homolle, *Les archives de l'intendance sacrée a Délos* (with plan). The best consecutive account is given in the *Guide Joanne*, *Grèce*, vol. ii. p. 443–464. For works of art found at Delos see ARCHÆOLOGY.

See also GREECE, IONIAN ISLANDS. (E. GR.)

**Delphi.**—The site of Delphi was bought by the French Government in 1891, and the peasant proprietors expropriated and transferred to the new village of Castri, a little farther to the west. Work began in the spring of 1892, and the site was rapidly cleared of earth by means of a light railway. The plan of the precinct is now easily traced, and with the help of Pausanias many of the buildings have been identified.

The ancient wall running east and west, commonly known as the Hellenico, has been found extant in its whole length, and the two boundary walls running up the hill at each end of it, traced. In the eastern of these was the main entrance by which Pausanias went in along the Sacred Way. This paved road is easily recognized as it zigzags up the hill, with treasuries and the bases of various offerings facing it on both sides. It mounts first westwards to an open space, then turns eastwards till it reaches the eastern end of the terrace wall that supports the temple, and then turns again and curves up north and then west towards the temple. Above this, approached by a stair, are the Lesche and the theatre, occupying respectively the north-east and north-west corner of the precinct. On a higher level still, a little to the west, is the stadium. There are several narrow paths and stairs that cut off the zigzags of the Sacred Way.

In describing the monuments discovered by the French excavators, the simplest plan is to follow the route of Pausanias. Outside the entrance is a large paved court of Roman date, flanked by a colonnade. On the north side of the Sacred Way, close to the main entrance, stood the offering dedicated by the Lacedæmonians after the battle of Ægospotami. It was a large quadrangular building of conglomerate, with a back wall faced with stucco, and stood open to the road. On a stepped pedestal facing the open stood the statues of the gods and the admirals, perhaps in rows above one another.

The statues of the Epigoni stood on a semicircular basis on the south side of the way. Opposite them stood another semicircular basis which carried the statues of the Argive kings, whose names are cut on the pedestal in archaistic characters, reading from right to left. Farther west was the Sicyonian treasury on the south of the way. It was in the form of a distyle Doric temple *in antis*, and had its entrance on the east. The present foundations are built of architectural fragments, probably from an earlier building of circular form on the same site. The sculptures from this treasury are in the museum, as are the other sculptures found on the site. These sculptures, which are in rough limestone, most likely belong to the earlier building, as their surface is in a better state of

preservation than could be possible if they had been long exposed to the air. The earlier treasury was probably destroyed either by earthquake or by the percolation of water through the terracing.

The Cnidian treasury stands on the south side of the way farther west. This building was originally surmised by the excavators to be the Siphnian treasury, but further evidence led them to change their opinion. The treasury was raised on a quadrangular structure, supported on its south side by the Hellenico, and built of tufa. The lower courses are left rough and were most likely hidden. A small distyle Ionic temple of marble stood on this substructure. The sculpture from this treasury, which ornamented its frieze and pediment, is of great interest in the history of the development of the art, and the fragments of architectural mouldings are of great delicacy and beauty. The whole work is perhaps the most perfect example we possess of the transitional style of the early 5th century. Standing back somewhat from the path just as it bends round up the hill is the Theban treasury. Farther north, where the path turns again, is the Athenian treasury. This structure, which was in the form of a small Doric temple *in antis*, appears to have suffered from the building above it having been shaken down by an earthquake. There can be no doubt about the identity of the building, for the basis on which it stands bears the remains of the dedicatory inscription, stating that it was erected from the spoils of Marathon. Almost all the sculptured metopes are in the museum, and are of the highest interest to the student of archaic art. The famous inscriptions with hymns to Apollo accompanied by musical notation were found on stones belonging to this treasury.

Above the Athenian treasury is an open space, in which is a rock which has been identified as the Sibyl's rock. It has steps hewn in it, and has a cleft. The ground round it has been left rough like the space on the Acropolis at Athens identified as the ancient altar of Athena. Here too was placed the curious column, with many flutes and an Ionic capital, on which stood the colossal sphinx, dedicated by the Naxians, that has been pieced together and placed in the museum.

A little farther on, but below the Sacred Way, is another open space, of circular form, which is perhaps the ἅλως or sacred threshing-floor on which the drama of the slaying of the Python by Apollo was periodically performed. Opposite this space, and backed against the beautifully jointed polygonal wall which has for some time been known, and which supports the terrace on which the temple stands, is the colonnade of the Athenians. A dedicatory inscription runs along the face of the top step, and has been the subject of much dispute. Both the forms of the letters and the style of the architecture show that the colonnade cannot date, as Pausanias says, from the time of the Peloponnesian War; M. Homolle now assigns it to the end of the 6th century. The polygonal terrace wall at the back, on being cleared, proves to be covered with inscriptions, most of them concerning the manumission of slaves.

After rounding the east end of the terrace wall, the Sacred Way turns northward, leaving the Great Altar, dedicated by the Chians, on the left. After passing the altar, it turns to the left again at right angles, and so enters the space in front of the temple. Remains of offerings found in this region include those dedicated by the Cyrenians and by the Corinthians. The site of the temple itself carries the remains of successive structures. Of that built by the Alcmæonids in the 6th century B.C. considerable remains have been found, some in the foundations of the later temple and some lying where they were thrown by the earthquake. The sculptures found have been assigned to this building, probably to the gables, as they are archaic in character, and show a remarkable resemblance to the sculptures from the pediment of the early temple of Athena at Athens. The existing foundations are these of the temple built in the 4th century. They give no certain information as to the sacred cleft and other matters relating to the oracle. Though there are great hollow spaces in the structure of the foundations, these appear merely to have been intended to save material, and not to have been put to any religious or other use. Up in the north-eastern corner of the precinct, standing at the foot of the cliffs, are the remains of the interesting Cnidian Lesche or Clubhouse. It was a long narrow building accessible only from the south, and the famous paintings were probably disposed around the walls so as to meet in the middle of the north side. Some scanty fragments of the lower part of the frescoed walls have survived; but they are not enough to give any information as to the work of Polygnotus.

At the north-western corner of the precinct is the theatre, one of the best preserved in Greece. The foundations of the stage are extant, as well as the orchestra, and the walls and seats of the auditorium. There are thirty-three tiers of seats in seven sets, and a paved diazoma. The sculptures from the stage front, now in the museum, have the labours of Heracles as their subject. The date of the theatre is probably early 2nd century B.C.

The stadium lies, as Pausanias says, in the highest part of the city to the north-west. It stands on a narrow plateau of ground supported on the south-east by a terrace wall. The seats have been cleared, and are in a state of extraordinary preservation. A few of those at the east end are hewn in the rock. No trace of the marble seats mentioned by Pausanias has been found, but they have probably been carried off for lime or building, as they could easily be removed. An immense number of inscriptions have been found in the excavations, and many works of art, including a bronze charioteer, which is one of the most admirable statues preserved from ancient times.

Provisional accounts of the excavations have appeared during the excavations in the *Bulletin de Correspondence Hellénique*. A summary is given in Frazer, *Pausanias*, vol. v. For the works of art discovered see ARCHÆOLOGY. (E. GR.)

**Delyannis, Theodore** (1826-——), Greek statesman, was born at Kalavrytra, Peloponnesus, in 1826. He studied law at Athens, and in 1843 entered the Ministry of the Interior. In 1862 he began to take an important part in politics after the deposition of King Otho. In 1867 he was Minister at Paris. On his return to Athens he became a member of successive cabinets in various capacities, and rapidly collected a party round him consisting of those who opposed his great rival, Tricoupis. In the so-called "Œcumenical Ministry" of 1877 he voted for war with Turkey, and on its fall he entered the cabinet of Koumoundoros as Minister for Foreign Affairs. He was a representative of Greece at the Berlin Congress in 1878. From this time forward, and particularly after 1882, when Tricoupis again came into power at the head of a strong party, the duel between these two statesmen was the leading feature of Greek politics (see GREECE, *History*). Delyannis first formed a cabinet in 1885, and his warlike policy resulted in the intervention of the Powers, who eventually blockaded the Piræus and other ports, and this brought about his downfall. He returned to power in 1890, with a radical programme, but his failure to deal with the financial crisis produced a conflict between him and the king, and his disrespectful attitude resulted in his summary dismissal in 1892. Delyannis, by his demagogic behaviour, evidently expected the public to side with him; but at the elections he was badly beaten. In 1895, how-

ever, he again became Prime Minister, and was at the head of affairs during the Cretan crisis and the opening of the war with Turkey in 1897. The humiliating defeat which ensued—though Delyannis himself had been led into the disastrous war policy to some extent against his will—caused his fall in April 1897, the king again dismissing him from office when he declined to resign. Delyannis kept his own seat at the election of 1899, but his following dwindled to small dimensions.

**Demotica,** a town of Turkey in Europe, in the sanjak and province of Adrianople, situated on the right bank of the Kizil-deli, near its junction with the Maritza, and on the Maritza Valley or Dédéahgatch-Kuleli-Bourgas Railway, about 35 miles south of Adrianople. It is of some industrial importance, the chief exports being pottery, for which it has some repute, linen, silk, cocoons, and grain. The population is about 12,000.

**Denbigh,** a maritime county of North Wales, is bounded N. by the Irish Sea, N.E. by Flint and Cheshire, S.E. by Flint and Shropshire, S. by Montgomery and Merioneth, and W. by Carnarvon.

*Area and Population.*—The area of the ancient county is 423,477 acres or 662 square miles. The population in 1881 was 111,957, and 117,872 in 1891, of whom 59,569 were males and 58,303 females; the number of persons per square mile being 178, and of acres to a person 3·59. In 1901 the population was 129,935. The area of the administrative county, as given in the census returns of 1891, was 424,435 acres, with a population of 118,843, but since then certain alterations have been made in the administrative area. In 1897 the part of the parish of Nanerch in Denbigh was transferred to Flint, and the part of the parish of Llanarmon yn Vale in Flint, and part of the parish of Erbistock were transferred from Flint to Denbigh. The area of the registration county is 386,416 acres, with a population in 1891 of 116,698. Within this area the increase of population between 1881 and 1891 was 3·29 per cent. The excess of births over deaths between 1871 and 1881 was 11,172, and the actual increase of population was 5716. The following table gives the numbers of marriages, births, and deaths, with the number and percentage of illegitimate births, for 1880, 1890, and 1898:—

| Year. | Marriages. | Births. | Deaths. | Illegitimate Births. | |
|---|---|---|---|---|---|
| | | | | No. | Per cent. |
| 1880 | 738 | 3535 | 2394 | 239 | 6·7 |
| 1890 | 871 | 3262 | 2313 | 173 | 5·3 |
| 1898 | 881 | 3572 | 2369 | 184 | 4·9 |

In 1891 there were in the county 554 natives of Scotland, 819 natives of Ireland, and 171 foreigners; while 38,310 persons could speak English, 37,195 Welsh, and 35,030 English and Welsh.

*Constitution and Government.*—The ancient county is divided into two parliamentary divisions, and it also includes the Denbigh district of parliamentary boroughs, consisting of Denbigh, Holt, Ruthin, and Wrexham. There are three municipal boroughs, Denbigh, Ruthin, and Wrexham. The following are urban districts—Abergele and Pensarn, Colwyn Bay and Colwyn, Llangollen, and Llanrwst. Denbighshire is in the North Wales Circuit, and assizes are held at Ruthin. The boroughs of Denbigh and Wrexham have separate commissions of the peace, but no separate court of quarter sessions. The ancient county, which is in the diocese of St Asaph's, contains 75 entire ecclesiastical parishes and districts, and part of one other.

*Education.*—The number of elementary schools on 31st August 1899 was 122, of which 48 were board and 74 voluntary schools, the latter including 70 National Church of England schools, 2 Roman Catholic, and 3 "British and other." The average attendance at board schools was 9288 and at voluntary schools 8258. The total school board receipts for the year ended 29th September 1899 were over £38,495. The income under the Technical Instruction Act was £69; that under the Agricultural Rates Act was over £1384.

*Agriculture.*—More than three-fifths of the total area of the county is under cultivation, and of this nearly three-fifths is in permanent pasture. There are also over 80,000 acres of mountain pasture grazed by sheep, and over 18,000 acres under woods. Only about 220 acres are under orchards. The acreage under corn crops has considerably decreased, the decrease being chiefly in the acreage under wheat, which now occupies about one-seventh of the corn crop acreage, barley occupying about two-sevenths, and oats nearly four-sevenths. Nearly three-fourths of the green crop area are occupied by turnips, and nearly one-fourth by potatoes.

*Industries and Trade.*—According to the annual report for 1898 of the chief inspector of factories (1900), the number of persons employed in factories and worshops in 1897 was 4690, as compared with 5359 in 1896. Non-textile factories employed 3379 persons, workshops 1150, the majority being engaged in the clothing industries. The total number of persons employed in connexion with mines and quarries in 1899 was 11,138. Coal-mining is the most important industry, Of the less valuable minerals there were raised (in 1899) 264,982 tons of clay, 204,599 tons of limestone, 23,042 tons of sandstone, and 28,840 tons of igneous rocks. Iron ore has almost ceased to be raised. The following table gives the productions of coal, lead, and zinc in 1890 and 1899:—

| Year. | Coal. | | Lead. | | Zinc. | |
|---|---|---|---|---|---|---|
| | Tons. | Value. | Tons. | Value. | Tons. | Value. |
| 1890 | 2,221,497 | £916,367 | 1416 | £12,821 | 6593 | £41,104 |
| 1899 | 2,512,104 | 973,440 | 1983 | 20,150 | 3273 | 25,976 |

See WILLIAMS and UNDERWOOD. *The Village Churches of Denbighshire, illustrated by geometrical, perspective, and detail drawings.* Denbigh, 1872. (T. F. H.)

**Denbigh,** a municipal and contributory parliamentary borough (uniting with Holt, Ruthin, and Wrexham), market-town, and county town of Denbighshire, Wales, 25 miles west of Chester. There are three Established, Roman Catholic, Baptist, Presbyterian, Methodist, and Congregationalist churches; also a new county school under the Welsh Intermediate Education Act, a Blue Coat school (both of old foundation), a school for 50 orphan girls maintained from funds left to the Drapers' Company, and, in the neighbourhood, the North Wales Asylum. The chief industries are tanning, boot-making, and slate-quarrying. Area of borough, 8868 acres. Population (1901), 6439.

**Denia,** a Mediterranean seaport of Spain, in the province, and 45 miles north-east of the town, of Alicante. Population (1897), 11,401. There are manufactures of woollen and linen cloths and esparto grass rugs. The export trade in fruit is considerable, the figures for raisins in 1898 being: to Great Britain, 13,000 tons; elsewhere, 12,000 tons; 150,000 barrels of grapes were also exported, exclusively to English ports. Of onions, 81,400 crates were despatched, practically all to North America. A breakwater, 1485 yards long, is in course of construction. 426 vessels of 165,246 tons entered in 1898, and 427 of 165,511 tons cleared. About half of these were small vessels engaged in the coasting trade, carrying agricultural produce. The chief imports were timber from the Baltic and coal from England.

**Denison, George Anthony** (1805–1896), English Churchman, brother of Mr Speaker Denison (Lord Ossington: 1800–1873), was born at Ossington, Notts, 11th December 1805, and educated at Eton and Christ Church, Oxford. In 1828 he was elected fellow of Oriel; and after a few years there as a tutor, during which he was ordained and acted as curate at Cuddesdon, he became rector of Broadwindsor, Dorset, and married (1838) the daughter of Mr Henley, M.P. In 1843 he was preferred by his brother, the Bishop of Salisbury, to the valuable living of East Brent, Somerset, and in 1851 was made Archdeacon of Taunton. For many years Archdeacon Denison represented the extreme High Tory party not only in politics but in the Church, regarding all "progressive" movements in education or theology as abomination, and vehemently repudiating the "higher criticism" from the days of *Essays and Reviews* (1860) to those of *Lux Mundi* (1890). In 1853 his views on the doctrine of the Real Presence subjected him to a suit for heresy on the complaint of a neighbouring parson, and after various complications he was condemned by the Archbishops' Court at Bath; but

on appeal the Court of Arches and the Privy Council quashed this judgment on a technical plea. The result was to make Archdeacon Denison a keen champion of the Ritualistic school. Until the end of his life he remained a protagonist in theological controversy and a keen fighter against latitudinarianism and liberalism; but the sharpest religious or political differences never broke his personal friendships and his Christian charity. Among other things for which he will be remembered was his origination of Harvest Homes. He died 21st March 1896.

**Denison,** a city of Grayson county, Texas, U.S.A., on the south bank of the Red river, at an altitude of 723 feet. It is regularly laid out on a level site, and has four wards. It has three railways, the Houston and Texas Central, the Missouri, Kansas, and Texas, and the Texas and Pacific, and is an important point in the collection and shipment of cotton. Population (1880), 3975; (1890), 10,958; (1900), 11,807, of whom 604 were foreign-born and 2251 negroes.

**Denizli,** chief town of a sanjak of the Aidin viláyet of Asia Minor, altitude 1167 ft. It is beautifully situated at the foot of Baba Dagh (Mt. Salbakus), on a tributary of the Churuk Szz (Lycus), and is connected by a branch line with the Smyrna-Dineir Railway. It took the place of Laodicea when that town was deserted during the wars between the Byzantines and Seljúk Turks, probably between 1158 and 1174. It had become a large and fine Moslem city in the 14th century, and was then called Ladík. The delightful gardens of Denizli have obtained for it the name of the Damascus of Anatolia. Population, 17,000 (Moslems, 14,500; Christians, 2500).

See RAMSAY. *Cities and Bishoprics of Phrygia*, vol. i. Oxford, 1895.—MURRAY. *Asia Minor Handbook.* 1895.

# DENMARK.

DENMARK, in the strictest geographical sense, comprises the northern portion of the Cimbric Peninsula called Jutland (Jylland) and the Danish Islands, which are situated mostly to the south-east of Jutland, between the southern part of the Cimbric Peninsula and the southern part of Sweden. Jutland lies between lat. 55° 16′ and lat. 57° 45′, whilst the islands are situated between lat. 54° 33′ and lat. 56° 8′. The westernmost point of Jutland is in long. 8° 4′ 54″, the easternmost point of the islands (apart from Bornholm) is in long. 12° 47′ 25″. The last-named island is situated in the Baltic, 76 miles east of the rest of Denmark, but in the same latitude as the southernmost of the other islands. According to the latest measurements, the total area of Denmark proper is 14,829 square miles, of which 9753 square miles fall to the share of Jutland, including the small islands belonging to it. The islands together cover 5076 square miles, and may be divided into four groups: the westernmost group, of which Fyen[1] is the largest, covers 1324 square miles; whilst Sealand [2] (Sjælland), with some adjacent smaller islands, occupies 2856 square miles; Lolland and Falster, which are to the south of Sealand, and separated from each other only by a very narrow channel, cover 671 square miles; Bornholm, finally, has an area of 225 square miles. Denmark is almost entirely surrounded by the sea, as it is connected with the Continent only at the southern frontier of Jutland, in which place the width of the peninsula is only about 37 miles. The west and north-west coasts of Jutland, from Blaavandshuk to the Scaw, are destitute of harbours, and girt by sandbanks very dangerous to shipping. In many places the sea has encroached very considerably; even in the 19th century entire villages were destroyed, but during the last twenty years of the century systematic efforts were made to secure the coast by groynes and embankments. A belt of sand dunes, from 500 yards to 7 miles wide, stretches along the whole of this coast for about 200 miles. The east coast of Jutland is of quite a different description, a series of long fjords entering deep into the country from the Cattegat. The longest of these is the Limfjord, which reaches the western coast of Jutland, and since 1825 has been in communication with the North Sea, so that the northern portion of Jutland is really an island; but the waters of the Limfjord, particularly in the western part, are so shallow that it offers no facility for navigation except to small craft. The Cattegat itself is full of sandbanks and difficult of navigation; in the winter it is often obstructed by drifting ice. From the Cattegat three passages lead to the Baltic, of which they form the outlet, namely, the Little Belt, the Great Belt, and the Sound (see BALTIC SEA). South of Copenhagen the passage is narrowed by the islands of Amager and Saltholm; and the channels on both sides of these islands have in their shallowest parts only 23 feet of water, besides being difficult to navigate. On the west coast of Jutland the ordinary tides of the North Sea are experienced, but in the Cattegat the difference between high and low water gradually diminishes towards the south. In the Belts and in the Sound the changes become almost imperceptible, and are obscured by the effects of winds and currents. In the Baltic there are no tides. No hill in Denmark exceeds 550 feet in height. Gudenaa in Jutland, the largest river in Denmark, has a course of 80 miles. Small lakes abound, but there are none of considerable size.

***Physical characteristics.***

The surface in Denmark is almost everywhere formed by the so-called Boulder Clay and what the Danish geologists call the Boulder Sand. The former, as is well known, owes its origin to the action of ice on the mountains of Norway in the Glacial period. It is unstratified; but by the action of water on it, stratified deposits have been formed, some of clay, containing remains of arctic animals, some. and very extensive ones, of sand and gravel. This boulder sand forms almost everywhere the highest hills, and besides, in the central part of Jutland, a wide expanse of heath and moorland apparently level, but really sloping gently towards the west. The deposits of the boulder formation rest generally on limestone of the Cretaceous period, which in many places comes near the surface and forms cliffs on the seacoast, of which the most interesting is the "Klint," on the island of Möen. But in the south-western parts a succession of strata, described as the Brown Coal or Lignite formations, intervenes between the chalk and the boulder clay; its name is derived from the deposits of lignite which occur in it. It is only on the island of Bornholm that older formations come to light. This island agrees in geological structure with the southern part of Sweden, and forms, in fact, the southernmost portion of the Scandinavian system. There the boulder clay lies immediately on the primitive rock, except in the south-western corner of the island, where a series of strata appear belonging to the Cambrian, Silurian, Jurassic, and Cretaceous formations, the true Coal formation, &c., being absent. Some parts of Denmark are supposed to have been finally raised out of the sea towards the close of the Cretaceous period; but as a whole the country did not appear above the water till about the close of the Glacial period. The upheaval of the country, a movement common to a large part of the Scandinavian peninsula, still continues, though slowly, north-east of a line drawn in a south-easterly direction from Nissumfjord on the west coast of Jutland, across the island of Fyen, a little south of the town of Nyborg. Ancient seabeaches, marked by accumulations of seaweed, rolled stones, &c., have been noticed

[1] "Fühnen" is German, not Danish.

[2] This spelling of the English name is nearer to the Danish and less liable to misunderstanding than that of Zealand, which is properly the name of a well-known island in Holland.

as much as 20 feet above the present level. But the upheaval does not seem to affect all parts equally. Even in historic times it has vastly changed the aspect and configuration of the country. It will easily be understood from the foregoing that the mineral products of Denmark are insignificant. Coal is found in Bornholm, several seams cropping out amongst the strata belonging to the Jurassic system. But the Bornholm coal is too hygroscopic to bear transport, and its heating power falls far short of that of English coal. The mines which have at different times been opened have proved failures, and their produce is only used for domestic purposes on the island itself. There is in Bornholm a deposit of kaolin of good quality, from which the Copenhagen porcelain factories take their supply. The Flora and Fauna of Denmark offer no peculiarities worthy of notice here. In ancient times extensive pine and fir forests existed, of which abundant remains are found in the peat bogs; but they have disappeared long ago, and at the present time firs and pines occur in Denmark only in plantations. The forests of Denmark consist of oak and beech, of which the latter is gradually getting the upper hand. The elm is comparatively rare in Denmark. The peat bogs are numerous, and supply a large proportion of the fuel used in the country. The sea fisheries are of importance, and a not inconsiderable quantity of fresh fish is exported to the interior of the Continent. Oysters are still found in some places, but have disappeared from many localities, where their abundance in ancient times is proved by the shell mounds on the coast. Such mounds occur in other countries too, but it was in Denmark that they were first recognized as being but the accumulated remains of the meals of the ancient population, which largely fed on oysters. Gudenaa is the only salmon river in Denmark. The climate of Denmark does not differ materially from that of Great Britain in the same latitude; but whilst the summer is a little warmer, the winter is colder, so that most of the evergreens which adorn an English garden in the winter cannot be grown in the open in Denmark. During 30 years the annual mean temperature varied from 43·88° to 46·22° in different years and different localities, the mean average for the whole country being 45·14°. The islands have, upon the whole, a somewhat warmer climate than Jutland. The mean temperature of the four coldest months, December to March, is 33·26°, 31·64°, 31·82°, and 33·98° respectively, or for the whole winter 32·7°; that of the summer, June to August, 59·2°, but considerable irregularities occur. Frost occurs on an average on 20 days in each of the four winter months, but only on a couple of days in either October or May. A fringe of ice generally lines the greater part of the Danish coasts on the eastern side for some time during the winter, and both the Sound and the Great Belt are at times impassable on account of ice. In some winters the latter is sufficiently firm and level to admit of sledges passing between Copenhagen and Malmö. The annual rainfall varies between 21·58″ and 27·87″ in different years and different localities. It is highest on the west coast of Jutland; the small island of Anholt in the Cattegat has an annual rainfall of only 15·78″. More than half the rainfall occurs from July to November, the wettest month being September, with an average of 2·95″; the driest month is April, with an average of 1·14″. Thunderstorms are frequent in the summer. South-westerly winds prevail from January to March, and from September to the end of the year. In April the east wind, which is particularly searching, is predominant, while westerly winds prevail from May to August.

**Population.** According to the census taken on 1st February 1901, the total population of Denmark was 2,449,540, as compared with 929,001 on the same date in 1801, showing an increase during the century in the proportion of 100 : 263. As compared with the total in 1890, namely, 2,172,380, the returns for 1901 are 12·76 per cent. higher, corresponding to an average annual increase of 1·09 per cent. during the ten years. The first four years of the decade were, however, far from favourable, owing to a great increase of mortality and at the same time of emigration, which latter cause reduced the increase which should have followed from the excess of births over deaths by nearly one-half. The actual annual increase during these years varied only from 0·54 per cent. to 0·68 per cent. In 1901 the average density of the population of Denmark was at the rate of 165·2 to the square mile, but varied much in the different parts. Jutland, which represents three-fifths of the total area of Denmark, and in 1901 had a population of 1,063,792, showed an average of only 109 inhabitants per square mile, whilst on the islands, which had a total population of 1,385,537, the average stood at 272·95, owing, on the one hand, to the fact that large tracts in the interior of Jutland are almost uninhabited, and on the other to the fact that the capital of the country, with its proportionately large population, is situated on the island of Sealand. The latter had a population of 960,053, or 336·2 inhabitants to the square mile including Copenhagen (with the suburbs of Fredriksberg and Sundby), but without the capital only 169·2. Not reckoning Sealand, the density of the population on the islands was at the rate of 191·7 to the square mile. In 1901, 936,565 persons were living in towns in Denmark, *i.e.*, 38·24 per cent. of the total population, whilst 1,512,975, or 61·77 per cent., were living in purely rural districts. In 1890 the town population amounted to 735,554, or 33·86 per cent. of the total, leaving but 1,436,826, or 66·14 per cent., for the rural districts. The movement of the population to the towns which is indicated by these figures commenced about the middle of the 19th century, and increased until very near its end. It has been stronger on the islands, where the rural population has increased by 5·3 per cent. only in eleven years, whereas in Jutland the increase of the rural population between 1890 and 1901 amounted to 12·0 per cent. (But for some of the causes of this increase see JUTLAND.) During the same years the population of Copenhagen increased by 24·94 per cent., namely, to 476,876 (491,340 with the environs); and the population of the provincial towns above 10,000 inhabitants by 43·6 per cent.; but in the smaller towns the augmentation only amounted to 20·5 per cent.

According to the census of 1890, the population of Denmark was divided as follows according to occupation, the figures including dependants:—

| Occupation. | Number. | Per cent. of Population. | Occupation. | Number. | Per cent. of Population. |
|---|---|---|---|---|---|
| Agriculture | 882,336 | 40·6 | Professions | 135,790 | 6·1 |
| Trades | 534,428 | 24·6 | Capitalists | 34,974 | 1·6 |
| Commerce | 172,929 | 7·9 | Pensioners | 17,723 | 0·8 |
| General labour | 162,928 | 7·5 | Annuitants | 40,276 | 1·8 |
| Fisheries | 32,912 | 1·5 | No certain livelihood | 44,667 | 2·0 |
| Navigation | 26,082 | 1·29 | Paupers | 39,014 | 1 79 |
| Transport, posts, telegraphs, &c. | 42,730 | 1·9 | Prisoners | 1,822 | .. |
| | | | Insane | 3,753 | .. |

In 1901, 1,193,448, or 48·72 per cent., of the population of Denmark were males; 1,256,092, or 51·28 per cent., were females. The number of marriages has increased, with little oscillation, from 14,975 in 1891 to 18,499 in 1900, that is, in a considerably greater ratio than the population. The number of divorces in 1900 was 391. The birth-rate appears to have oscillated during the period in question between 29·3 and 38·8 per thousand, the highest number of children born alive being 72,141 in 1900. On an average, 51·3 per cent. of the children born annually are boys, and the male sex remains in excess until about the 20th year, from which age the female sex preponderates in increasing ratio with advancing age. Of all children born annually an average of 9·6 per cent. are illegitimate. In some rural districts the ratio is as low as 3·5 per cent., but in Copenhagen it reaches 20·2 per cent. 12 per cent. of the illegitimate children born alive had mothers who were under 20 years of age. The still-born numbered, in 1899, 2·47 per cent. of all births, but amongst them 12·8 per cent. were illegitimate. Between the middle and the end of the 19th century the rate of mortality decreased most markedly for all ages. The annual death-rate per thousand may be taken to have varied during 1890–1900 between 19·5 in 1891 and 15·1 in 1898 (17·4 in 1900). The annual number of suicides, which used to average 555, declined towards the close of the 19th century, and was 523 for the period 1896–1900.

Emigration, which for some time seriously affected the population of Denmark, diminished in the 'nineties. In 1892 the number of emigrants to Transatlantic places rose to 10,422, but in 1900 it was only 3570. The great bulk of them go to the United States; next in favour is Canada. In 1890 there were 70,900 persons, foreigners, living in Denmark, of whom 33,802 were born in Sweden, 20,824 were Schleswigers, 10,823 were natives of other parts of Germany, and 3385 were Norwegians. From 1891 to 1900 2525 foreigners were naturalized.

The Danish Parliament, called the "Rigsdag," consists of two chambers, the Folkething and the Landsthing, but the constitution contains no indication of any difference in their attributes. The Landsthing, however, is evidently intended to form the conservative element in the constitutional machinery. Whilst the 114 members of the Folkething are elected in the usual way by universal suffrage, 12 out of the 66 members of the Landsthing are life members nominated by the Crown. The remaining 54 members of the Landsthing are returned according to a method of proportionate representation by a body of deputy electors. Of these latter one-half are elected in the same way as members of the Folkething, without any property qualification for the voters; the other half of the deputy electors are chosen in the towns by those who during the last preceding year were assessed on a certain minimum of income, or paid at least a certain amount in rates and taxes. In the rural districts the deputy electors returned by election are supplemented by an equal number of those who have paid the highest amounts in taxes and county rates together. In this manner a representation is secured for fairly large minorities, and what is considered a fair share of influence on public affairs given to those who contribute the most to the needs of the State. The Faroes, which form an integral part of the kingdom of Denmark in the wider sense, are represented in the Danish Parliament, but not the other dependencies of the Danish Crown. For administrative purposes the country is divided into 18 so-called "Amts," or counties. The principal civil officer in each of them is the "Amtmand." Local affairs are managed by "Amtsraad" and "Sogneraad," corresponding to the English county council and parish council. These institutions date from 1841, but they have undergone several modifications since. The members of these councils are elected on a system similar to that applied to the elections for the Landsthing. The same is the case with the provincial town councils. That of Copenhagen is elected by those who are rated on an income of at least 400 crowns (£22). The burgomasters are appointed by the Crown, except in Copenhagen, where they are elected by the town council, subject to royal approbation.

*Government.*

For the administration of justice Denmark is divided into "Herreds" or Hundreds; as, however, they are mostly of small extent, several are generally served by one judge, "Herredsfoged"; the townships are likewise separate jurisdictions, each with a "Byfoged." There are 126 such local judges, each of whom deals with all kinds of cases arising in his district, and is also at the head of the police. There are two intermediary Courts of Appeal, one in Copenhagen, another in Viborg; the Supreme Court of Appeal sits at Copenhagen. In the capital the different functions are more divided. There is also a Court of Commerce and Navigation, on which leading members of the trading community serve as assessors. In the country, Land Commissions similarly constituted deal with many questions affecting agricultural holdings. A peculiarity of the Danish system is that, with few exceptions, no civil cause can be brought before a court until an attempt has been made at effecting an amicable settlement. This is mostly done by so-called Committees of Conciliation, but in some cases by the court itself before commencing formal judicial proceedings. In this manner three-fifths of all the causes are settled, and many which remain unsettled are abandoned by the plaintiffs. In 1897 the courts disposed of about 30,000 civil cases; 3689 persons (2838 males and 851 females) were convicted of various crimes; 3573 were punished for police offences; whilst 33,005 police cases were disposed of without formal judgment, on the defendant agreeing to pay a fine. Sanitary matters are under the control of a Board of Health. The whole country is divided into districts, in each of which a medical man is appointed with a salary, who is under the obligation to attend to poor sick and assist the authorities in medical matters, inquests, &c. The relief of the poor is well organized, mostly on the system of out-door relief. Many workhouses have been established for indigent persons capable of work. There are many almshouses and similar institutions.

*Justice.*

The National or State Church of Denmark is officially styled "Evangelically Reformed," but is popularly described as Lutheran. In 1890 its members numbered 2,136,329, or 98·44 per cent. of the total population. 10,624 belonged to free extra-parochial congregations of Lutherans. The members of other Christian communities numbered 14,502, of which 1252 were Calvinists, 137 Anglicans, 2301 Methodists, 4556 Baptists, 2609 Irvingites, and 3647 Roman Catholics. There were 4080 Jews, mostly in Copenhagen. 941 were returned as Mormons, and 2560 as not professing any positive religion. There are seven dioceses, the Primate being the Bishop of Sealand, who resides at Copenhagen, but his cathedral is at Roeskilde. There are 72 rural deaneries, and 988 pastorates, of which the greater part comprise more than one parish; the number of parish churches is 1721. The benefices are almost without exception provided with good residences and glebes, and the tithes, &c., generally afford a comfortable income. The bishops have fixed salaries in lieu of tithes appropriated by the State.

*Religion.*

Every child is bound to attend the parish school at least from the 7th to the 13th year, unless the parents can prove that it receives suitable instruction in other ways. The schools are under the immediate control of school boards appointed by the parish councils, but of which the incumbent of the parish is *ex-officio* member; superior control is exercised by the Amtmand, the rural dean, and the bishop, under the Minister for Church and Education. The instruction in primary schools is gratuitous. Secondary public schools are provided in towns, in which moderate school fees are paid. There are 13 public grammar schools. Nearly all schools are day-schools. There are only two public schools which, though on a much smaller scale, resemble the great English schools, namely, those of Soro and Herlufsholm, both founded by private munificence. Private schools are mostly more or less under public control. The number of children in Danish schools was, in 1898, 364,091, of whom 307,633 were in municipal schools, 6838 in grammar schools, and 49,620 in other schools, including infant schools, &c. The University, Copenhagen, which was founded in 1479, has 53 professors, besides a varying number of lecturers. Connected with it are an observatory, museums of national history, a botanical garden, various collections and laboratories, as well as a good library. The matriculations average 350 a year. Amongst the numerous other institutions for the furtherance of science and training of various kinds may be mentioned the large polytechnic schools; the High School for Agriculture and Veterinary Art, with 22 professors, besides lecturers; the Royal Library (500,000 vols., 20,000 MSS.); the Royal Society of Sciences; the Museum of Northern Antiquities; the Society of Northern Antiquaries, &c. &c. The art museums of Denmark are not considerable, except the Museum of Thorvaldsen, but much is done to provide first-rate training in the fine arts and their application to industry. The Royal Academy of Arts has 7 professors, besides assistant teachers, and its schools are frequented by about 200 students annually. Finally, it may be mentioned that comparatively much money is available from public funds and regular parliamentary grants for furthering science and arts by temporary subventions to students, authors, artists, and others of insufficient means, in order to enable them to carry out particular works, to profit by foreign travel, &c.

*Education.*

The following is a summary of the items of expenditure in the Danish Budget for 1900–01:—

*Finance.*

| | | | |
|---|---|---|---|
| Civil List | Kr. 1,000,000 | or | £55,555 |
| Appanages to the Royal Family | 203,200 | ,, | 11,289 |
| Parliament (payment of members, &c.) | 200,000 | ,, | 11,111 |
| Council of State (pay of Ministers, &c.) | 119,016 | ,, | 6,612 |
| Interest on Public Debt | 7,059,300 | ,, | 392,183 |
| Reduction of Debt | 1,802,731 | ,, | 100,152 |
| Pensions | 3,349,540 | ,, | 186,086 |
| Army | 11,022,419 | ,, | 612,357 |
| Navy | 7,787,310 | ,, | 432,629 |
| Civil Service | 26,957,512 | ,, | 1,497,639 |
| Iceland, annual grant | 76,564 | ,, | 4,254 |
| Public Works (new railways, &c.) | 10,370,907 | ,, | 576,161 |
| Loans and Advances | 2,229,950 | ,, | 123,886 |
| | Kr.72,178,449 | | £4,009,914 |

The items of estimated actual revenue for 1900–01 were as follow:—

| | | | |
|---|---|---|---|
| Customs | Kr.33,176,000 | or | £1,843,111 |
| Excise and Beer Tax | 9,170,000 | ,, | 509,444 |
| Land and House Tax | 10,577,500 | ,, | 587,639 |
| Stamps | 3,550,000 | ,, | 197,222 |
| Carry forward | Kr.56,473,500 | | £3,137,416 |

| | | | |
|---|---|---|---|
| Brought forward | Kr.56,473,500 | or | £3,137,416 |
| Death Duties . . | 1,400,000 | ,, | 77,778 |
| Tax on Transfers of Property . . . | 916,000 | ,, | 50,889 |
| Legal Fees (Patents, &c.) | 2,555,100 | ,, | 141,950 |
| State Railways . . | 2,958,916 | ,, | 164,384 |
| Post and Telegraphs . | 222,581 | ,, | 12,366 |
| State Lottery . . | 1,090,000 | ,, | 60,556 |
| Crown Lands, Forests, &c.) . . . | 893,424 | ,, | 49,635 |
| Interest on Reserve . | 643,000 | ,, | 35,722 |
| Interest on Debts to the State . . . | 841,127 | ,, | 46,729 |
| Sundry receipts . . | 1,221,517 | ,, | 67,862 |
| | Kr.69,215,165 | | £3,845,287 |

The amount of the internal debt on 1st April 1900, is estimated at Kr.77,708,810 or £4,317,156, bearing interest of 3½ per cent. (excepting some small amounts on which 3, 4, 4½, or 5 per cent. are paid), whilst that of the foreign debt is placed at Kr.138,512,250 or £7,695,125, bearing 3 per cent. interest, with the exception of a very small amount on which 4 per cent. is paid. The revenue and expenditure of the Faroes are included in the budget for Denmark proper, but Iceland and the West Indies have their separate budgets. The Danish Treasury receives nothing from these possessions; on the contrary, Iceland receives an annual grant, and the West Indian Islands have been heavily subsidized by the Danish finances to assist the sugar industry. The administration of Greenland entails an annual loss of Kr.156,273 or £8682, which is posted on the budget of the Ministry of Finance. The financial position of the municipalities in Denmark is generally good. The ordinary budget of Copenhagen amounts to about £1,100,000 a year.

***Industry.***

The main source of wealth in Denmark is agriculture. No information is available as to the average size of agricultural holdings in Denmark, but there are statistics from which their value may be estimated. Rates and taxes on land are mostly levied according to a uniform system of assessment, the unit of which is called a "Tönde Hartkorn." The Td. Htk., as it is usually abbreviated, has further subdivision, and is intended to correspond to the same value of land throughout the country. The Danish measure for land is a "Tonde Land" (Td. L.), which is equal to 1·363 statute acres. Of the best ploughing land a little over 6 Td. L., or about 8 acres, go to a Td. Htk., but of unprofitable land a Td. Htk. may represent 300 acres or more. On the islands and in the more fertile part of Jutland the average is about 10 Td. L., or 13½ acres. Woodland, tithes, &c., are also assessed to Td. Htk. for fiscal purposes, but the total assessment of agricultural land in Denmark is 369,161 Td. Htk., exclusive of the island of Bornholm, where the assessment is somewhat different, though the general state of agricultural holdings is the same as in other parts. The selling value of land has lately been declining, on account of the agricultural depression which has affected Denmark as well as England, but according to an official calculation based on the actual open sales which had taken place, it was, in 1895, Kr.5155 or £286 per Td. Htk. A homestead with land assessed less than 1 Td. Htk. is legally called a "Huus" or "Sted," *i.e.*, cottage, whilst a farm assessed at 1 Td. Htk. or more is called "Gaard," *i.e.*, farm. Most of the land in Denmark is freehold and cultivated by the owner himself, and comparatively little land is let on lease except very large holdings and glebe farms. Farms of between 1 and 12 Td. Hartkorn are called "Böndergaarde," or peasant farms, and are subject to the restriction that such a holding cannot lawfully be joined to or entirely merged into another. They may be subdivided, and portions may be added to another holding, but the homestead, with a certain amount of land, must be preserved as a separate holding for ever. According to the return of 1895, there were in Denmark (apart from the island of Bornholm) 73,889 "gaarde," of which 2031 were assessed at 12 Td. Htk. or more (not a few exceeding 100 Td. Htk.), their total assessment being 56,822 Td. Htk., or 15·4 per cent. of the total assessment of the country. Only 30 of these gaarde were not freehold. This class, of course, includes the "Herregaarde," or seats of the nobility and landed gentry. 12,858 holdings were "Böndergaarde," or peasant farms, and as the total assessment of this class of holdings amounts to 267,302 Td. Htk., it will be seen that the peasants in Denmark hold 72·9 per cent. of all the land according to its value. As regards their size, 44,557, or 30 per cent., were assessed at from 1 to 4 Td. Htk.; 23,638, or 32·9 per cent., were assessed at 4 to 8 Td. Htk.; the remainder at about 8 Td. Htk. In the rural districts there are, besides, 159,147 "Huse," or cottages with land, assessed at less than 1 Td. Htk., of which 141,439, or 89·1 per cent., were freehold and occupied by the owners. There were, besides, 32,946 cottages without land, of which 20,271, or 61·5 per cent., were freehold and occupied by the owners. Of late years an annual sum has been voted by the Rigsdag, out of which loans are granted to cottagers who desire to purchase small freehold plots. The total area of Denmark is 6,892,110 Td. Ld., or 9,393,945 statute acres, of which 5,097,357 Td. Ld., or 6,957,697 acres—that is, fully 74 per cent.—are agricultural land. Only 563,059 acres of this total are meadow land. In 1896 the ploughed land, 6,384,637 acres, was utilized as follows:—2,876,124 acres were sown with cereals, namely, wheat 85,001 acres, rye 718,228 acres, barley 691,181 acres, oats 1,085,847 acres, and mixed cereals 295,867 acres; 533,221 acres were sown with green fodder, potatoes, roots, and other minor crops; whilst 2,333,869 acres were under grass in rotation, and 621,423 acres were in fallow. The quantity of grain harvested in 1896 is stated to have been, in English quarters, 446,875 of wheat, 2,432,875 of rye, 2,574,500 of barley, 4,667,125 of oats, and 1,301,138 of mixed grain. There is, of course, a good deal of variation from year to year, but the above figures are near the average. During the last forty years of the 19th century dairy-farming was greatly developed in Denmark, and brought to a high degree of perfection by the application of scientific methods and the best machinery, as well as by the establishment of joint dairies. The Danish Government has assisted this development by granting money for experiments, and by a rigorous system of inspection for the prevention of adulteration. According to the latest returns (1898), 449,264 horses, 1,743,440 head of cattle, 1,178,514 swine, 1,074,413 sheep, were kept in Denmark, but only 31,803 goats and 139 donkeys. Rabbits, which are not found wild in Denmark, are bred for export, their number being given as 81,475. The garden land in Denmark amounted, in 1896, to 81,152 acres. The woods cover 665,584 acres, or fully 7 per cent. of the area, and their preservation is considered of so much importance that private owners are under strict control as regards cutting of timber. The woods consist mostly of beech, which is principally used for fuel, but pines were extensively planted during the 19th century. Efforts are being made to plant the extensive heaths in Jutland with pine trees (see JUTLAND). Peat bogs occupy 188,650 acres; heaths, moors, and other essentially waste lands, 909,795 acres.

The fishery along the coasts of Denmark is of some importance, both on account of the supply of food obtained thereby for the population of the country, and on account of the export; but the good fishing grounds, not far from the Danish coast, particularly in the North Sea, are mostly worked by the fishing vessels of other nations, which are so numerous that the Danish Government is obliged to keep gunboats stationed there in order to prevent encroachments on territorial waters.

The factories of Denmark supply mainly local needs. The Copenhagen china has a good reputation. In 1897 there were only 165 establishments employing each more than 100 hands; the largest are those engaged in the construction of engines and iron ships, of which there are 4, employing together about 3000 persons. Trade-unionism flourishes in Denmark, and strikes are of frequent occurrence.

***Commerce.***

The total value of Danish commerce has risen from £22,433,000 in 1874 to £51,132,000 in 1900, in which year the exports were valued at £21,865,000, the imports at £29,267,000. The commerce of Denmark is mainly based on home production and home consumption, but a certain quantity of goods is imported with a view to re-exportation, for which the free port and bonded warehouses at Copenhagen give facilities. The value of goods exported in 1900 and declared to be of foreign origin was £6,203,000. The main features of the trade of Denmark will be seen from the subjoined table for 1899, in which the different articles are classed as follows:—I. Live animals. II. Articles of animal food.

| | Import. | Export. | Balance. | Foreign Goods Exported. |
|---|---|---|---|---|
| | £ | £ | £ | £ |
| I. Live animals . | 123,800 | 1,080,500 | − 956,700 | 200 |
| II. Animal food . | 3,145,700 | 13,145,300 | −9,999,600 | 1,457,900 |
| III. Breadstuffs . | 6,205,100 | 1,158,400 | +5,046,700 | 553,400 |
| IV. Colonial produce . . | 2,214,000 | 711,500 | +1,502,500 | 660,600 |
| V. Alcoholic drinks . . | 413,700 | 206,800 | + 206,900 | 165,300 |
| VI. Textiles, &c. . | 3,659,800 | 848,600 | +2,811,200 | 684,400 |
| VII. Timber . . | 1,408,000 | 117,000 | +1,291,000 | 85,000 |
| VIII. Raw materials, vegetable and animal . | 2,913,400 | 1,454,400 | +1,459,000 | 815,200 |
| IX. Minerals and metal goods | 5,385,000 | 1,070,100 | +4,314,900 | 701,800 |
| X. Other goods . | 1,869,200 | 458,400 | +1,410,800 | 119,400 |
| | 27,337,700 | 20,251,000 | +7,086,700 | 5,243,200 |

III. Breadstuffs and foods for animals. IV. Colonial produce, conserves, &c. V. Alcoholic drinks. VI. Materials for spinning and weaving, woven fabrics and garments. VII. Timber and

wooden goods. VIII. Other raw materials of vegetable or animal origin, including all kinds of manures and oils. IX. Raw materials of mineral nature, and goods manufactured from them. X. All other goods. In the third column − indicates excess of export, + excess of import; the fourth column indicates the value of the foreign goods re-exported, which is included in the general figure for imports and exports.

In the first of the classes under which the articles have been summarized the most important is horned cattle, of which 37,736 head were exported in 1899, all home-bred; only 1130 head were imported. The trade in live sheep and swine, which was formerly important, has now mostly been converted into a dead-meat trade. In the second class, butter is the principal article, the export in 1899 amounting to 158,303,300 ℔ avoir., valued for export at £7,708,600, or 38·6 per cent. of the total value of Danish exports. Of this quantity 134,898,700 ℔, valued at £6,611,900, was home produce, whilst the remaining 23,404,600 ℔ (value £1,096,700) had been imported chiefly from Russia (also Siberia) and Sweden and re-exported as of foreign origin. In 1899 there was a further importation of butter for home consumption of 14,183,000 ℔ The production of margarine amounted in the year 1899–1900 to 35,849,054 ℔ besides which 5,622,290 ℔ were imported, but only 384,889 ℔ were exported, margarine being largely consumed in Denmark instead of the butter which is exported. Next to butter the most important article of Danish export is bacon, of which 164,667,953 ℔, valued at £3,083,620, were exported in 1899, all home produce excepting 5,782,349 ℔, which had been previously imported, together with 2,721,240 ℔ for home consumption. Eggs were exported in 1899 to the number of 302,994,800. The first two classes of articles, living animals and articles of food of animal origin, are the only ones of which the exportation exceeds the importation; with regard to all other goods, the reverse is the case: at the same time, from about 26 per cent. to 92 per cent. of the export in each of these classes consisted of foreign goods re-exported. Denmark had formerly a considerable net export of grain, but this is not the case now, owing partly to the increase of the population in wealth and number, and consequently to the greater consumption of breadstuffs, partly to the great development of dairy-farming and cattle-feeding. The proportionally large importation of timber is caused by the scarcity of native timber suitable for building purposes, the plantations of firs and pines being as yet insufficient to produce the quantity required, and the quality of the wood being inferior beyond the age of about 40 years. The large importation of minerals and metals and goods made from them is, of course, likewise caused by the natural poverty of the country in these respects. Coals were imported to the value of £1,953,700. Among the unclassified articles may be noted vessels built abroad, which in the statistics for 1899 figure with a value of £654,100 on the import side against £175,400 on the export side.

The value of the trade (1899) of Denmark with particular countries will be seen from the following table:—

| Countries. | Total. | Import. | Export. | Balance. |
|---|---|---|---|---|
| | £ | £ | £ | £ |
| Great Britain | 17,607,400 | 5,584,400 | 12,023,000 | − 6,438,600 |
| Germany . | 11,718,000 | 8,014,000 | 3,704,000 | + 4,310,000 |
| Sweden . | 4,804,500 | 2,868,000 | 1,936,500 | + 931,500 |
| United States | 4,722,100 | 4,341,400 | 380,700 | + 3,960,700 |
| Russia . . | 2,943,800 | 2,043,300 | 900,500 | + 1,142,800 |
| Norway . | 1,042,000 | 416,200 | 625,800 | − 209,600 |
| France . . | 697,300 | 619,300 | 78,000 | + 541,300 |
| Other countries | 4,053,600 | 3,451,100 | 602,500 | + 2,848,600 |
| Total . | 47,588,700 | 27,337,700 | 20,251,000 | + 7,086,700 |

The value of the trade of Denmark proper with the other parts of the Danish State, which is included in the category of "Other countries," was as follows in 1899:—

| | | | | |
|---|---|---|---|---|
| Faröes . . . . | Imports, | £19,400; | exports, | £35,300 |
| Iceland . . . . | ,, | 133,500 | ,, | 147,800 |
| Greenland . . . | ,, | 35,000 | ,, | 18,000 |
| Danish West Indies . . | ,, | 4,200 | ,, | 5,200 |
| Total . . | | £192,100 | | £206,300 |

***Shipping.*** The commercial fleet of Denmark comprised at the end of 1900, exclusive of small craft under 4 tons, 3017 sailing vessels, with a collective tonnage of 146,900 tons. Of these, 395 (tonnage in all, 98,799) each exceeded 100 tons register. The steamers numbered 483, with a total tonnage of 247,353, of which 312, with a collective tonnage of 242,770, each exceeded 100 tons. The total number of clearances to or from foreign ports in 1899 was 63,774, of which 32,889 were Danish vessels, 30,885 foreign vessels, but with this difference, that whilst the clearances of Danish steamers numbered 21,783, and those of Danish sailing vessels amounted only to 11,092, the reverse proportion held good for foreign vessels, of which 11,013 were steamers and 19,872 sailing vessels, chiefly Swedish. A large proportion of Danish vessels are engaged in the carrying trade between foreign ports; in 1899, 4703 clearances of Danish vessels so employed occurred in Great Britain, lesser number in other countries.

Denmark has long possessed a very complete set of excellent roads. The length of the railways, which for the most part are State property, was at the close of 1900, 1810 miles.

***Communications, posts, &c.*** In the course of 1900 about 20,000,000 of passengers were carried, travelling 587,500,000 miles, besides luggage, about 3,571,000 tons of goods were carried. There were in 1899, 274 post offices, 583 sub-offices, and 10,115 letter-boxes; 90,382,094 ordinary letters and 915,323 letters containing money were carried, of which respectively 17,228,427 and 69,157 for or from places abroad. 3,260,627 parcels were carried, of which 641,191 to or from places abroad. 83,499,502 newspapers and periodicals were carried, of which 2,789,143 to or from abroad. 2,628,616 postal orders passed through the post, of which 328,754 to or from abroad; finally, 983,457 different sums were collected for senders of parcels, of which 85,927 were in respect of parcels to or from places abroad. The telegraph service is carried on by the General Post Office. There were 480 stations; the length of the lines was 3850 miles. 2,056,613 telegrams were carried, of which 595,433 passed between Danish stations, 842,886 between Danish and foreign stations, whilst 618,294 passed through the Danish system between foreign stations. Of the second class, 257,562 were exchanged with Germany, 231,651 with Great Britain, 103,704 with Sweden, 83,404 with Norway, 53,026 with Russia, and 30,338 with America. There are 171 telephone stations in connexion with the State telegraph.

The principal bank of Denmark is the National Bank at Copenhagen, which is the only one authorized to issue notes. The total amount of these is £5,333,334; the notes are of the value of 10 kr. (1 krone = 1s. 1⅓d.), 50, 100, and 500 kr. Next in importance are the Danske Landmands Bank, the Handels Bank, and the Private Bank, all at Copenhagen. The provincial banks are very numerous; many of them are at the same time savings banks. This latter class numbered at the close of 1899, 532. The total of their deposits was £37,410,320, their rate of interest, with few exceptions, 3½ to 4 per cent.. There exists, besides, in Denmark 15 mutual loan associations (Kreditforeninger), whose business is the granting of loans on mortgage. The total of the money lent by these institutions was £46,121,780. Registration of mortgages is compulsory in Denmark, and the system is extremely simple, a fact which has been of the greatest importance for the improvement of the country. There are comparatively large institutions for insurance of all kinds in Denmark. The largest office for life insurance is a State institution. By law of 9th April 1891 a system of old-age pensions has been established for the benefit of persons over 60 years of age. The total number of those who in 1898 were in receipt of permanent and direct assistance was 40,759, of whom 27,629 were without encumbrance, whilst 13,130 were heads of families having in all 15,897 persons depending on them. Those assisted were fully 17 per cent. of all persons in Denmark above 60 years of age, but the number will of course increase. 69·15 per cent. lived in the rural districts.

The unit of the Danish monetary system is the krone (crown), equal to 1s. 1⅓d., which is divided into 100 öre; consequently 7½ öre are equal to one penny. Since 1873 gold has been the standard, and gold pieces of 20 and 10 kroner are coined, but not often met with, as the public prefers bank-notes.

As regards the dependencies and colonies of Denmark, see articles on Faröes, Greenland, Iceland, and St Thomas. Their areas and population are as follows:—

| | | | |
|---|---|---|---|
| Faröes (1900) . . . | Area, 511 sq. m.; | population, | 15,230 |
| Iceland (1890). . . | ,, 40,426 ,, | ,, | 70,927 |
| Danish West Indies (1900) | ,, 138 ,, | ,, | 30,504 |
| Greenland (1890) . | about 43,000 ,, | ,, | 10,576 |
| Total area (without Greenland), 41,075 sq. m. | | Total . | 127,237 |

The recent political history of Denmark offers very little of general interest. The country has not been engaged in the political struggles of Europe, and has been left in peace.

***Recent History.*** As long as Napoleon III. was on the throne, Denmark could still hope one day to recover the lost province of North Schleswig, and when war broke out in 1870 between France and Germany, public opinion inclined to an active sympathy with France. The rapid course of that campaign, however, compelled Denmark to observe neutrality. After its close any *rapprochement* to the new German Empire was distasteful to the people. In the circumstances, Austria and Germany agreed, in October 1878, to the abolition of clause 5 of the Treaty of Prague, which, to the great surprise of the Danes, was carried out at the very time the Danish Court was preparing to give expression to its anti-German

sentiments on the marriage of the Princess Thyra to the Duke of Cumberland. The most noticeable feature in the internal history of Denmark is the constitutional struggle which has been going on for many years between successive Governments and the Left party, which commands an overwhelming majority in the Folkething. No practical questions of great importance have been at the bottom of this disagreement save that of the fortification of Copenhagen. The Government considered this necessary, because without it the capital was exposed to a *coup de main* at any time, while the Left opposed it as a piece of aggressive militarism, which would be unnecessary if Denmark only proclaimed her neutrality in any war that might arise. For this reason the majority of the Folkething refused to sanction the outlay, but the Government, considering that the danger was real, and that the neutrality of a State cannot be secured by her own declaration but depends on the goodwill of her neighbours, which cannot be guaranteed, nevertheless carried out the work by means of a huge accumulated surplus. In the course of this conflict the majority in the Folkething even went the length of refusing supplies altogether; but under the Premiership of M. Estrup the Government collected the revenue nevertheless, and sought its justification in the approval of the Landsthing, whose political power according to the Charter is in every respect equal to that of the Folkething. This procedure met with no serious resistance in the country. The election in the spring of 1901 resulted in the return to the Folkething of 76 members of the Reform party of the Left, 16 members of the Moderate Left, 14 Social Democrats, and only 8 members of the Right, the party which had held the reins of power for so many years. Professor Deuntzer, one of the law professors in the University of Copenhagen, became the head of a Government composed of prominent men drawn from the different sections of his own side of the Folkething, and including amongst the number a simple peasant as Minister of Agriculture. The most prominent articles in the policy of the new Government were a reform of the customs, a readjustment of the system of taxation, a reform of the judicial procedure, a reform of primary education, and a reduction in the expenditure for military purposes.

Danish literature is dealt with below. As regards the intellectual life of the Danish nation in other respects during the last quarter of the 19th century, there is not much that calls for notice. During the earlier part of the century not a few men could be mentioned who enjoyed an exceptional reputation in various departments of science, but they have gradually died away, and their places have not been filled. Danish scientists, nevertheless, continue to contribute their full share to the advancement of knowledge, and a full account of what has been published would occupy considerable space. The Society of Sciences, that of Northern Antiquaries, the Natural History and the Botanical Societies, &c., still publish their transactions and proceedings, but the *Naturhistorisk Tidsskrift*, of which 14 volumes with 259 plates were published 1861–84, and which really was in the foremost rank in its department, ceased with the death in 1884 of the editor, the distinguished zoologist, I. C. Schiödte. Another extremely valuable publication of wide general interest, the *Meddelelser om Grönland* which is published by the Commission for the Exploration of Greenland, and of which 23 volumes, richly illustrated with maps, &c., have appeared, is still being continued. Amongst the works on the history of Denmark which have appeared, the most important is the *History of Denmark and Norway since 1720*, by E. Holm.

What may be called the modern "art" current, with its virtues and vices, is as strong in Denmark as in England (see SCHOOLS OF PAINTING). In architecture the prevailing fashion is a return to the style of the first half of the 17th century, called the Christian IV. Style.

## DANISH LITERATURE.

The development of imaginative literature in Denmark became very closely defined during the latter half of the 19th century. The romantic movement culminated in several poets of great eminence, whose deaths prepared the way for a new school. In 1874 Bödtcher passed away, in 1875 Hans Christian Andersen (*q.v.*), in the last week of 1876 Winther (*q.v.*), and the greatest of all, Frederik Paludan-Müller (*q.v.*). The field was, therefore, left open to the successors of those idealists, and in 1877 the reaction began to be felt. The eminent critic, Dr Georg Brandes (*q.v.*), had long foreseen the decline of pure romanticism, and had advocated a more objective and more exact treatment of literary phenomena. Accordingly, as soon as all the great planets had disappeared a new constellation was perceived to have risen, and all the stars in it had been lighted by the enthusiasm of Brandes. The new writers were what he called Naturalists, and their sympathies were with the latest forms of exotic, but particularly of French literature. Among these fresh forces three immediately took place as leaders — Jacobsen, Drachmann, and Schandorph. In J. P. Jacobsen (1847–1885) (*q.v.*) Denmark was now taught to welcome the greatest artist in prose which she has ever possessed; his romance of *Marie Grubbe* led off the new school with a production of unexampled beauty. But Jacobsen died young, and the work was really carried out by his two companions. Holger Drachmann (*b.* 1846) (*q.v.*) began life as a marine painter; and a first little volume of poems, which he published in 1872, attracted slight attention. In 1877 he came forward again with one volume of verse, another of fiction, a third of travel; in each he displayed great vigour and freshness of touch, and he rose at one leap to the highest position among men of promise. He has known how, through many vicissitudes, to retain his place, and Drachmann is to-day, without rival, the leading imaginative writer in Denmark. For many years he made the aspects of life at sea his particular theme, and he contrived to rouse the patriotic enthusiasm of the Danish public as it had never been roused before. His various and unceasing productiveness, his freshness and vigour, and the inexhaustible richness of his lyric versatility, early brought Drachmann to the front and kept him there. Meanwhile prose imaginative literature was ably supported by Sophus Schandorph (1836–1901), who had been entirely out of sympathy with the idealists, and had taken no step while that school was in the ascendant. In 1876, in his fortieth year, he was encouraged by the change in taste to publish a volume of realistic stories, *Country Life*, and in 1878 a novel, *Without a Centre.* He has some relation with Guy de Maupassant as a close analyst of modern types of character, but he has more humour. He has been compared with such Dutch painters of low life as Teniers. His talent reached its height in the novel called *Little Folk*, 1880, a most admirable study of lower middle-class life in Copenhagen. He was for a while, without doubt, the leading living novelist, and he went on producing works of great force, in which, however, a certain monotony is apparent. The three leaders had meanwhile been joined by certain younger men who took a prominent position. Among these Karl Gjellerup and Erik Skram were the earliest. Gjellerup (*b.* 1857), whose first works of importance date from 1878, was long uncertain as to the direction of his powers; he was poet, novelist, moralist, and biologist in one; at length he settled down into line with the new realistic school, and produced in 1882 a satirical novel of manners which had a great success, *The Disciple of the Teutons.* Erik Skram (*b.* 1847) had in 1879 written a solitary novel, *Gertrude Coldbjörnsen*, which created a sensation, and was hailed by Brandes as exactly representing the "naturalism" which he desired to see encouraged; but Skram has written little else of importance. Other writers of reputation in the naturalistic school were Edvard Brandes (*b.* 1847) and Herman Bang (*b.* 1858). Peter Nansen (*b.* 1861) has come into wide notoriety as the author, in particularly beautiful Danish, of a series of stories of a pronouncedly sexual type, among which *Maria* (1894) has been the most successful. Meanwhile, several of the elder generation,

unaffected by the movement of realism, continued to please the public. Three lyrical poets, H. V. Kaalund (1818–1885), Carl Ploug (1813-1894), and Christian Richardt (1831–1892), of very great talent, were not yet silent, and among the veteran novelists were still active H. F. Ewald (*b.* 1821) and Thomas Lange (*b.* 1829). During the whole of this period the most popular writer of Denmark was J. C. C. Brosböll (1816–1900), who wrote, under the pseudonym Carit Etlar, a vast number of tales. The admirable prose-writer Meier Goldschmidt survived until 1887. Sophus Bauditz (*b.* 1850) has persevered in composing novels which attain a wide general popularity. Mention must be made also of the dramatist Christian Molbech (1821–1888) and of the miscellaneous writer Erik Bögh (1822–1899).

Between 1885 and 1892 there was a transitional period in Danish literature. Up to that time all the leaders had been united in accepting the naturalistic formula, which was combined with an individualist and a Radical tendency. In 1885, however, Drachmann, already the recognized first poet of the country, threw off his allegiance to Brandes, denounced the exotic tradition, declared himself a conservative, and took up a national and patriotic attitude. He was joined a little later by Gjellerup, while Schandorph remained staunchly by the side of Brandes. The camp was thus divided. New writers began to make their appearance, and, while some of these were staunch to Brandes, others were inclined to hold rather with Drachmann. Of the authors who came forward during this period of transition, the strongest has proved to be Henrik Pontoppidan (*b.* 1857), in 1902 perhaps the first living novelist of Denmark. In some of his books he reminds the reader of Tourgenieff. Pontoppidan published in 1898 the first volume of a great novel entitled *Lykke-Per*, the biography of a typical Jutlander named Per Sidenius, a work to be completed in eight volumes, of which four had appeared by 1901. Since 1893 no great features of a fresh kind have revealed themselves. The Danish public, grown tired of realism, and satiated with pathological phenomena, have returned to a study of their own national characteristics. The cultivation of verse, which was greatly discouraged in the 'eighties, has returned. Drachmann, who is really a talent of immense force, has persisted, and he is now supported by excellent younger poets of his school. J. J. Jörgensen (*b.* 1866), a Catholic decadent, is one of these who have been very prolific. Otto C. Fönss (*b.* 1853) has published seven little volumes of graceful lyrical poems in praise of gardens and of farm-life. Andreas Dolleris (*b.* 1850), of Vejle, published the same number of books between 1879 and 1901, and is an occasional poet of considerable merit. Alfred Ipsen (*b.* 1852) should also be mentioned as a poet and critic. Valdemar Rördam, whose *The Danish Tongue* was the lyrical success of 1901, must also be named. Some attempts have been made to transplant the theories of the symbolists to Denmark, but without signal success. On the other hand, something of a revival of naturalism is to be observed in the powerful studies of low life admirably written by Karl Larsen (*b.* 1860), of which *At Sixteen* was published in 1901.

The drama has long flourished in Denmark, and it has not ceased to do so within the last quarter of a century. The principal theatres are liberally open to fresh dramatic talent of every kind, and the great fondness of the Danes for this form of entertainment gives unusual scope for experiments in halls or private theatres; nothing is too eccentric to hope to obtain somewhere a fair hearing. Drachmann has produced with great success several romantic dramas founded on the national legends. Most of the novelists and poets already mentioned have essayed the stage, and to those names should be added these of Ernst von der Recke (*b.* 1848) and Gustav Wied (*b.* 1858).

In theology Denmark has not approached the preceding generation, in which such writers as Clausen (1793–1877), and still more Martensen (1808–84), lifted the prestige of Danish divinity to a high point. But in history the Danes have been very active. Jens Peter Trap (1810–1885) concluded his great statistical account of Denmark in 1879. The 16th century has been made the object of the investigations of Troels Lund (*q.v.*). About 1880 several of the younger historians formed the plan of combining to investigate and publish the sources of Danish history; in this the indefatigable Johannes Steenstrup (*b.* 1844) was prominent. The domestic history of the country began, about 1885, to occupy the attention of Holm, O. Nielsen, and the veteran Frederik Barfod (1811–1896). The naval histories of G. Lütken attracted much notice. Besides the names already mentioned, A. D. Jorgensen (1840–1897), Fridericia, and Mollerup have all distinguished themselves in the excellent school of Danish historians. Since 1896 a composite history of Denmark, on a very large scale, has been undertaken by some leading historians. In philosophy nothing has been published of the highest value. Martensen's *Jakob Böhme* (1881) really belongs to an earlier period. H. Höffding (*b.* 1843) has been the most prominent contributor to psychology, and an enthusiastic disciple of Mr Herbert Spencer. Alfred Lehmann (*b.* 1858) has, since 1896, attracted a good deal of attention by his sceptical investigation of psychical phenomena. F. Rönning has written on the history of thought in Denmark. In the criticism of art, Julius Lange (1838–1896), and later Karl Madsen, have done excellent service. In literary criticism that eminent master of thought and language Dr Georg Brandes (*b.* 1842) has been active and predominant throughout the whole of this period. His influence on his age has been greater than that of any other Dane. Thor Lange (*b.* 1851) has been an excellent critic and a useful translator. (E. G.)

**Denny** and **Dunipace,** a police burgh (1876) of Stirlingshire, Scotland, formed of two towns on opposite sides of the river Carron, 25¼ miles north-east of Glasgow by rail. The industries are iron-founding, paper-making, engineering, chemical manufacture, brick-making, and coal-mining. There is a cottage hospital and a public hall and library. The churches are Established, three United Free, and Roman Catholic. The Denny public school had an average attendance of 802 in 1898–99, Dunipace public school 176, and Denny Roman Catholic school 178. Population (1881), 4081; (1901), 5158.

**Dentistry.**—Dentistry is a special department of medical science, embracing the structure, function, and therapeutics of the mouth and its contained organs, together with their surgical and prosthetic treatment. As a distinct vocation it is first alluded to by Herodotus (500 B.C.). There are evidences that at an earlier date the Egyptians and Hindoos attempted to replace lost teeth by attaching wood or ivory substitutes to adjacent sound teeth by means of threads or wires, but the gold fillings reputed to have been found in the teeth of Egyptian mummies have upon investigation been shown to be superficial applications of gold leaf for ornamental purposes. The impetus given to medical study in the Grecian schools by the followers of Æsculapius and especially Hippocrates (500 to 400 B.C.) developed among the practitioners of medicine and surgery considerable knowledge of dentistry. Galen (A.D. 131) taught that the teeth were true bones existing before birth, and to him is credited the belief that the upper canine teeth receive branches from the nerve which supplies the eye, and hence should be called "eye-teeth." Albucasis (A.D. 1006?) describes the operation by which artificial

***Historical sketch.***

crowns are attached to adjacent sound teeth. Vesalius (1514), Ambroise Paré, Scaliger, Kerckring, Malpighi, and lesser anatomists of the same period contributed dissertations which threw some small amount of light upon the structure and functions of the teeth. The operation of transplanting teeth is usually attributed to John Hunter (1728–1793), who practised it extensively, and gave to it additional prominence by transplanting a human tooth to the comb of a cock, but the operation was alluded to by Ambroise Paré (1509–1590), and there is evidence to show that it was practised even earlier. Leeuwenhoek in 1678 described with much accuracy the tubular structure of the dentine, thus making the most important contribution to the subject which had appeared up to that time. Until the latter part of the 18th century extraction was practically the only operation for the cure of toothache.

The early contributions of France exerted a controlling influence upon the development of dental practice. Urbain Hémard, surgeon to the Cardinal Georges of Armagnac, whom Dr Blake (1801) calls an ingenious surgeon and a great man, published in 1582 his *Researches upon the Anatomy of the Teeth, their Nature and Properties.* Of Hémard, M. Fauchard says: "This surgeon had read Greek and Latin authors, whose writings he has judiciously incorporated in his own works." In 1728 Fauchard, who has been called the Father of Modern Dentistry, published his celebrated work, entitled *Le Chirurgien Dentiste ou Traité des dents.* The preface contains the following statement as to the existing status of dental art and science in France, which might have been applied with equal truth to any other European country:—"The most celebrated surgeons having abandoned this branch of surgery, or having but little cultivated it, their negligence gave rise to a class of persons who, without theoretic knowledge or experience, and without being qualified, practised it at hazard, having neither principles nor system. It was only since the year 1700 that the intelligent in Paris opened their eyes to these abuses, when it was provided that those who intended practising dental surgery should submit to an examination by men learned in all the branches of medical science, who should decide upon their merits." After the publication of Fauchard's work the practice of dentistry became more specialized and distinctly separated from medical practice, the best exponents of the art being trained as apprentices by practitioners of ability, who had acquired their training in the same way from their predecessors. Fauchard suggested porcelain as an improvement upon bone and ivory for the manufacture of artificial teeth, a suggestion which he obtained from Réaumur, the French savant and physicist, who was a contributor to the Royal Porcelain Manufactory at Sévres. Later, Duchateau, an apothecary of St Germain, made porcelain teeth, and communicated his discovery to the Academy of Surgery in 1776, but kept the process secret. Du Bois Chémant carried the art to England, and the process was finally made públic by M. Du Bois Foucou. M. Fonzi improved the art to such an extent that the Athenæum of Arts in Paris awarded him a medal and crown, 14th March 1808.

In Great Britain the 19th century brought the dawning of dental science. The work of Dr Blake in 1801 on the Anatomy of the Teeth was distinctly in advance of anything previously written on the subject. Joseph Fox was one of the first members of the medical profession to devote himself exclusively to dentistry, and his work is a repository of the best practice of his time. The processes described, though comparatively crude, involve principles in use at the present time. Thomas Bell, the successor of Fox as lecturer on the Structure and Disease of the Teeth at Guy's Hospital, published his well-known work in 1829. About this period numerous publications on dentistry made their appearance, notably those of Koecker, Johnson, and Waite, followed somewhat later by the admirable work of Alexander Nasmyth (1839). By this time Cuvier, Serres, Rousseau, Bertin, Herissant, and others in France had added to the knoweledge of human and comparative dental anatomy, while Retzius, of Sweden, and Weber, Rosenmüller, Schreger, Purkinje, Fraenkel, and Müller in Germany were carrying forward the same lines of research. The sympathetic nervous relationships of the teeth with other parts of the body, and the interaction of diseases of the teeth with general pathological conditions, were clearly established. Thus a scientific foundation was laid, and dentistry came to be practised as a specialty of medicine. Certain minor operations, however, such as the extraction of teeth and the stopping of caries in an imperfect way, were still practised by barbers, and the empirical practice of dentistry, especially of those operations which were almost wholly mechanical, had developed a considerable body of dental artisans who, though without medical education in many cases, possessed a high degree of manipulative skill. Thus there came to be two classes of practitioners, the first regarding dentistry as a specialty of medicine, the latter as a distinct and separate calling.

In America representatives of both classes of dentists began to arrive from England and France about the time of the Revolution. Among these were John Wooffendale (1766), a student of Robert Berdmore of Liverpool, surgeon-dentist to H.M. George III.; James Gardette (1778), a French physician and surgeon; and Joseph Lemaire (1781), a French dentist who went out with the army of Count Rochambeau. During the winter of 1781–82, while the Continental army was in winter quarters at Providence, R.I., Lemaire found time and opportunity to practise his calling, and also to instruct one or two persons, notably Josiah Flagg, probably the first American dentist. Dental practice was thus established upon American soil, where it has produced such fertile results.

**Course of training.**

Until well into the 19th century apprenticeship afforded the only means of acquiring a knowledge of dentistry. The profits derived from the apprenticeship system fostered secrecy and quackery among many of the early practitioners; but the more liberal minded and better educated of the craft developed an increasing opposition to these narrow methods. In 1837 a local association of dentists was formed in New York, and in 1840 a national assocation, "The American Society of Dental Surgeons," the object of which was "to advance the science by free communication and interchange of sentiments." The first dental periodical in the world, the *American Journal of Dental Science*, was issued in June 1839, and in November 1840 was established the Baltimore College of Dental Surgery, the first college in the world for the systematic education of dentists. Thus the year 1839–40 marks the birth of the three factors essential to professional growth in dentistry. All this, combined with the refusal of the medical schools to furnish the desired facilities for dental instruction, placed dentistry for the time being upon a footing entirely separate from general medicine. Since then the curriculum of study preparatory to dental practice has been systematically increased both as to its content and length, until in all fundamental principles it is practically equal to that required for the training of medical specialists, and in addition includes the technical subjects peculiar to dentistry. In England, and to some extent upon the Continent, the old apprenticeship system is retained as an adjunct to the college course, but it is rapidly dying out, as it has already done in America. Owing to the regula-

tion by law of the educational requirements, the increase of institutions devoted to the professional training of dentists has been rapid in all civilized countries, and during the past twenty years especially so in the United States. Great Britain possesses upwards of twelve institutions for dental instruction, France two, Germany and Switzerland six, all being based upon the conception that dentistry is a department of general medicine. In the United States there were in 1878 twelve dental schools, with about 700 students; in 1899 there were fifty-six schools, with 7633 students. Of these fifty-six schools, thirty-six are departments of universities or of medical institutions, and there is a growing tendency to regard dentistry from its educational aspect as a special department of the general medical and surgical practice.

Recent studies have shown that besides being an important part of the digestive system, the mouth sustains intimate relationship with the general nervous system, and is important as the portal of entrance for the majority of the bacteria that cause specific diseases. This fact has rendered more intimate the relations between dentistry and the general practice of medicine, and has given a powerful impetus to scientific studies in dentistry.

*Research.*

Through the researches of Tomes, Mummery, Hopewell Smith, Williams, and others in England, Hertwig, Weil, and Röse in Germany, Andrews, Sudduth, and Black in America, the minute anatomy and embryology of the dental tissues have been worked out with great fulness and precision. In particular, it has been demonstrated that certain general systemic diseases have a distinct oral expression. Through their extensive nervous connexions with the largest of the cranial nerves and with the sympathetic nervous system, the teeth frequently cause irritation resulting in profound reflex nervous phenomena, which are curable only by removal of the local tooth disorder. Gout, lithæmia, scurvy, rickets, lead and mercurial poisoning, and certain forms of chronic nephritis, produce dental and oral lesions which are either pathognomonic or strongly indicative of their several constitutional causes, and are thus of great importance in diagnosis. The most important dental research of modern times is that which was carried out by Professor W. D. Miller of Berlin (1884) upon the cause of caries of the teeth, a disease said to affect the human race more extensively than any other. Miller demonstrated that, as previous observers had suspected, caries is of bacterial origin, and that acids play an important rôle in the process. The disease is brought about by a group of bacteria which develop in the mouth, growing naturally upon the débris of starchy or carbohydrate food, producing fermentation of the mass, with lactic acid as the end product. The lactic acid dissolves the mineral constituent of the tooth structure, calcium phosphate, leaving the organic matrix of the tooth exposed. Another class of germs, the peptonising and putrefactive bacteria, then convert the organic matter into liquid or gaseous end products. The accuracy of the conclusions obtained from his analytic research was synthetically proved, after the manner of Koch, by producing the disease artificially. Caries of the teeth has been shown to bear highly important relation to more remote or systemic diseases. Exposure and death of the dental pulp furnishes an avenue of entrance for disease-producing bacteria, by which invasion of the deeper tissues may readily take place, causing necrosis, tuberculosis, actinomycosis, phlegmon, and other destructive inflammations, certain of which, affecting the various sinuses of the head, have been found to cause meningitis, chronic empyema, metastatic abscesses in remote parts of the body, paralysis, epilepsy, and insanity.

*Operative Dentistry.*—The art of dentistry is usually divided arbitrarily into *operative dentistry*, the purpose of which is to preserve as far as possible the teeth and associated tissues, and *prosthetic dentistry*, the purpose of which is to supply the loss of teeth by artifical substitutes.

***Filling or stopping.***

The filling of carious cavities was probably first performed with lead, suggested apparently by an operation recorded by Celsus (100 B.C.), who recommended that frail or decayed teeth be stuffed with lead previous to extraction, in order that they might not break under the forceps. The use of lead as a filling was sufficiently prevalent in France during the 17th century to bring into use the word *plombage*, which is still occasionally applied in that country to the operation of filling. Gold as a filling material came into general use about the beginning of the 19th century.[1] The earlier preparations of gold were so impure as to be virtually without cohesion, so that they were of use only in cavities which had sound walls for its retention. In the form of rolls or tape it was forced into the previously cleaned and prepared cavity, condensed with instruments under heavy hand pressure, smoothed with files, and finally burnished. Tin foil was also used to a limited extent and by the same method. Improvements in the refining of gold for dental use brought the product to a fair degree of purity, and, about 1855, led to the invention by Dr Robert Arthur of Baltimore of a method by which it could be welded firmly within the cavity. The cohesive properties of the foil were developed by passing it through an alcohol flame, which dispelled its surface contaminations. The gold was then welded piece by piece into a homogeneous mass by plugging instruments with serrated points. In this process of cold-welding, the mallet, hitherto in only limited use, was found more efficient than hand pressure, and was rapidly developed. The primitive mallet of wood, ivory, lead or steel, was supplanted by a mallet in which a hammer was released automatically by a spring condensed by pressure of the operator's hand. Then followed mallets operated by pneumatic pressure, by the dental engine, and finally by the electro-magnet, as utilized in 1867 by Bonwill. These devices greatly facilitated the operation, and made possible a partial or entire restoration of the tooth-crown in conformity with anatomical lines.

The dental engine in its several forms is the outgrowth of the simple drill worked by the hand of the operator. It is used in removing decayed structure and for shaping the cavity for inserting the filling. From time to time its usefulness has been extended, so that it is now used for finishing fillings and polishing them, for polishing the teeth, removing deposits from them and changing their shapes. Its latest development, *the dento-surgical engine*, is of heavier construction and is adapted to operations upon all of the bones, a recent addition to its equipment being the spiral osteotome of Cryer, by which, with a minimum shock to the patient, fenestra of any size or shape in the brain-case may be made, from a simple trepanning operation to the more extensive openings required in intra-cranial operations. The rotary power may be supplied by the foot of the operator, or by hydraulic or electric motors. The rubber dam invented by S. C. Barnum of New York (1864) provided a means for protecting the field of operations from the oral fluids, and extended the scope of operations even to the entire restoration of tooth-crowns with cohesive gold foil. Its value has been found to be even greater than was at first anticipated. In all operations involving the exposed dental pulp or the pulp-chamber and root-canals, it is the

[1] The filling of teeth with gold foil is recorded in the oldest known book on dentistry, *Artzney Buchlein*, published anonymously in 1530, in which the operation is quoted from Mesue (A.D. 857), physician to the Caliph Haroun al-Raschid.

only efficient method of mechanically protecting the field of operation from invasion by disease-producing bacteria.

The difficulty and annoyance attending the insertion of gold, its high thermal conductivity, and its objectionable colour have led to an increasing use of amalgam, gutta-percha, and cements of zinc oxide mixed with zinc chloride or phosphoric acid. Recently much attention has been devoted to restorations with porcelain. A piece of platinum foil of ·001 inch thickness is burnished and pressed into the cavity, so that a matrix is produced exactly fitting the cavity. Into this matrix is placed a mixture of powdered porcelain and water or alcohol, of the colour to match the tooth. The mass is carefully dried and then fused until homogeneous. Shrinkage is counteracted by additions of porcelain powder, which are repeatedly fused until the whole exactly fills the matrix. After cooling, the matrix is stripped away and the porcelain is cemented into the cavity. When the cement has hardened, the surface of the porcelain is ground and polished to proper contour. If successfully made, porcelain fillings are scarcely noticeable. Their durability remains to be tested.

**Dental therapeutics.**

Until recent times the exposure of the dental pulp inevitably led to its death and disintegration, and, by invasion of bacteria *viâ* the pulp canal, set up an inflammatory process which eventually caused the loss of the entire tooth. A rational system of therapeutics, in conjunction with proper antiseptic measures, has made possible both the conservative treatment of the dental pulp when exposed, and the successful treatment of pulp-canals when the pulp has been devitalized either by design or disease. The conservation of the exposed pulp is affected by the operation of capping. In capping a pulp, irritation is allayed by antiseptic and sedative treatment, and a metallic cap, lined with a non-irritant sedative paste, is applied under aseptic conditions immediately over the point of pulp exposure. A filling of cement is superimposed, and this, after it has hardened, is covered with a metallic or other suitable filling. The utility of arsenious acid for devitalizing the dental pulp was discovered by J. R. Spooner of Montreal, and first published in 1836 by his brother Shearjashub in his *Guide to Sound Teeth*. The painful action of arsenic upon the pulp was avoided by the addition of various sedative drugs,—morphia, atropia, iodoform, &c.,—and its use soon became universal. Of late years it is being gradually supplanted by immediate surgical extirpation under the benumbing effect of cocaine salts. By the use of cocaine also the pain incident to excavating and shaping of cavities in tooth structure may be controlled, especially when the cocaine is driven into the dentine by means of an electric current. To fill the pulp-chamber and canals of teeth after loss of the pulp, all organic remains of pulp tissue should be removed by sterilization, and then, in order to prevent the entrance of bacteria, and consequent infection, the canals should be perfectly filled. Upon the exclusion of infection depends the future integrity and comfort of the tooth. Numberless methods have been invented for the operation. Pulpless teeth are thus preserved through long periods of usefulness, and even those remains of teeth in which the crowns have been lost are rendered comfortable and useful as supports for artificial crowns, and as abutments for assemblages of crowns, known as bridge-work.

The discoloration of the pulpless tooth through putrefactive changes in its organic matter were first overcome by bleaching it with chlorine. Small quantities of calcium hypochlorite are packed into the pulp-chamber and moistened with dilute acetic acid; the decomposition of the calcium salt liberates chlorine *in situ*, which restores the tooth to normal colour in a short time. The cavity is afterwards washed out, carefully dried, lined with a light-coloured cement, and filled. More efficient bleaching agents of recent introduction are hydrogen dioxide in a 25 per cent. solution or a saturated solution of sodium dioxide; they are less irritating and much more convenient in application. Unlike chlorine, these do not form soluble metallic salts which may subsequently discolour the tooth. Hydrogen dioxide may be carried into the tooth structure by the electric current. In which case a current of not less than forty volts controlled by a suitable graduated resistance is applied with the patient in circuit, the anode being a platinum-pointed electrode in contact with the dioxide solution in the tooth cavity, and the cathode a sponge or plate electrode in contact with the hand or arm of the patient. The current is gradually turned on until two or three milliamperes are indicated by a suitable ammeter. The operation requires usually twenty to thirty minutes.

Malposed teeth are not only unsightly but prone to disease, and may be the cause of disease in other teeth, or of the associated tissues. The impairment of function which their abnormal position causes has been found to be the primary cause of disturbances of the general bodily health; for example, enlarged tonsils, chronic pharyngitis and nasal catarrh, indigestion, and malnutrition. By the use of springs, screws, vulcanized caoutchouc bands, elastic ligatures, &c., as the case may require, practically all forms of dental irregularity may be corrected, even such protrusions and retrusions of the front teeth as cause great disfigurement of the facial contour.

**Extraction.**

The extraction of teeth, an operation which until quite recent times was one of the crudest procedures in minor surgery, has been reduced to exactitude by improved instruments, designed with reference to the anatomical relations of the teeth and their alveoli, and therefore adapted to the several classes of teeth. The operation has been rendered painless by the use of anæsthetics. The anæsthetic generally employed is nitrous oxide, or laughing-gas, the use of which was discovered in 1844 by Horace Wells, a dentist of Hartford, Conn., U.S.A. Chloroform and ether, as well as other general anæsthetics, have been employed in extensive operations because of their more prolonged effect; but chloroform, especially, is dangerous, owing to its effect upon the heart, which in many instances has suddenly failed during the operation. Ether, while less manageable than nitrous oxide, has been found to be practically devoid of danger. The local injection of solutions of cocaine and allied anæsthetics into the gum-tissue is extensively practised; but is attended with danger, from the toxic effects of an overdose upon the heart, and the local poisonous effect upon the tissues, which lead in numerous cases to necrosis and extensive sloughing.

**Artificial teeth.**

*Dental Prosthesis.*—The fastening of natural teeth or carved substitutes to adjoining sound teeth by means of thread or wire preceded their attachment to base-plates of carved wood, bone, or ivory, which latter method was practised until the introduction of swaged metallic plates. Where the crown only of a tooth or those of several teeth were lost, the restoration was effected by engrafting upon the prepared root a suitable crown by means of a wooden or metallic pivot. When possible, the new crown was that of a corresponding sound tooth taken from the mouth of another individual; otherwise an artificial crown carved from bone or ivory, or sometimes from the tooth of an ox, was used. To replace entire dentures a base-plate of carved hippopotamus ivory was constructed, upon which were mounted the crowns of natural teeth, or later those of porcelain. The manufacture of a denture of this character was tedious and uncertain,

and required much skill. The denture was kept in place by spiral springs attached to the buccal sides of the appliance above and below, which caused pressure upon both jaws, necessitating a constant effort upon the part of the unfortunate wearer to keep it in place. Metallic swaged plates were introduced in the latter part of the 18th century. An impression of the gums was taken in wax, from which a cast was made in plaster of Paris. With this as a model, a metallic die of brass or zinc was prepared, upon which the plate of gold or silver was formed, and then swaged into contact with the die by means of a female die or counter-die of lead. The process is essentially the same to-day, with the addition of numerous improvements in detail, which have brought it to a high degree of perfection. The discovery, by Gardette of Philadelphia in 1800, of the utility of atmospheric pressure in keeping artificial dentures in place led to the abandonment of spiral springs. A later device for enhancing the stability is the vacuum chamber, a central depression in the upper surface of the plate, which when exhausted of air by the wearer, materially increases the adhesion. The metallic base-plate is used also for supporting one or more artificial teeth, being kept in place by metallic clasps fitting to, and partially surrounding, adjacent sound natural teeth, the plate merely covering the edentulous portion of the alveolar ridge. It may also be kept in place by atmospheric adhesion, in which case the palatal vault is included, and the vacuum chamber is utilized in the palatal portion to increase the adhesion.

In the construction usually practised, porcelain teeth are attached to a gold base-plate by means of stay-pieces of gold, perforated to receive the platinum pins baked in the body of the tooth. The stay-pieces or backings are then soldered to the pins and to the plate by means of high-fusing gold solder. The teeth used may be single or in sections, and may be with or without an extension designed in form and colour to imitate the gum of the alveolar border. Even when skilfully executed, the process is imperfect in that the jointing of the teeth to each other, and their adaptation to the base-plate, leaves crevices and recesses, in which food débris and oral secretions accumulate. To obviate these defects the enamelled platinum denture was devised. Porcelain teeth are first attached to a swaged base-plate of pure platinum by a stay-piece of the same metal soldered with pure gold, after which the interstices between the teeth are filled, and the entire surface of the plate, excepting that in contact with the palate and alveolar border, is covered with a porcelain paste called the body, which is modelled to the normal contour of the gums, and baked in a muffle furnace until vitrified. It is then enamelled with a vitreous enamel coloured in imitation of the colour of the natural gum, which is applied and fired as before, the result being the most artistic and hygienic denture known. This is commonly known as the continuous gum method. Originating in France in the early part of the 19th century, and variously improved by several experimenters, it was brought to its present perfection by Dr John Allen of New York about 1846–47. Dentures supported upon cast bases of metallic alloys and of aluminium have been employed as substitutes for the more expensive dentures of gold and platinum, but have had only a limited use, and are less satisfactory.

Metallic bases were used exclusively as supports for artificial dentures until in 1855–56 Charles Goodyear, jun., patented in England a process for constructing a denture upon vulcanized caoutchouc as a base. Several modifications followed, each the subject of patented improvements. Though the cheapness and simplicity of the vulcanite base has led to its abuse in incompetent hands, it has on the whole been productive of much benefit. It has been used with great success as a means of attaching porcelain teeth to metallic bases of gold, silver, and aluminium. It is extensively used also in correcting irregular positions of the teeth, and for making interdental splints in the treatment of fractures of the jaws. For the mechanical correction of palatal defects causing imperfection of deglutition and speech, which comes distinctly within the province of the prosthetic dentist, the vulcanite base produces the best-known apparatus. Two classes of palatal mechanism are recognized—the obturator, a palatal plate, the function of which is to close perforations or clefts in the hard palate, and the artificial velum, a movable attachment to the obturator or palatal plate, which closes the opening in the divided natural velum and, moving with it, enables the wearer to close off the naso-pharynx from the oral cavity in the production of the guttural sounds. Vulcanite is also used for extensive restorations of the jaws after surgical operations or loss by disease, and in the majority of instances wholly corrects the deformity.

For a time vulcanite almost supplanted gold and silver as a base for artificial denture, and developed a generation of practitioners deficient in that high degree of skill necessary to the construction of dentures upon metallic bases. The recent development of crown-and-bridge work has brought about a renaissance, so that a thorough training is more than ever necessary to successful practice in mechanical dentistry. The simplest crown is of porcelain, and is engrafted upon a sound natural tooth-root by means of a metallic pin of gold or platinum, extending into the previously enlarged root-canal and cemented in place. In another type of crown the point between the root-end and the abutting crown-surface is encircled with a metallic collar or band, which gives additional security to the attachment and protects the joints from fluids or bacteria. Crowns of this character are constructed with a porcelain facing attached by a stay-piece or backing of gold to a plate and collar, which has been previously fitted to the root-end like a ferule, and soldered to a pin which projects through the ferule into the root-canal. The contour of the lingual surface of the crown is made of gold, which is shaped to conform to the anatomical lines of the tooth. The shell-crown consists of a reproduction of the crown entirely of gold plate, filled with cement, and driven over the root-end, which it closely encircles. The two latter kinds of crowns may be used as abutments for the support of intervening crowns in constructing bridge-work. When artificial crowns are supported not by natural tooth-roots but by soldering them to abutments, they are termed dummies. The number of dummies which may be supported upon a given number of roots depends upon the position and character of the abutments, the character of the alveolar tissues, the age, sex, and health of the patient, the character of the occlusion or bite, and the force exerted in mastication. In some cases a root will not properly support more than one additional crown; in others an entire bridge denture has been successfully supported upon four well-placed roots. Two general classes of bridge-work are recognized, namely, the fixed and the removable. Removable bridge-work, though more difficult to construct, is preferable, as it can be more thoroughly and easily cleansed. When properly made and applied to judiciously selected cases, the bridge denture is the most artistic and functionally perfect restoration of prosthetic dentistry.

***Modern methods.***

The entire development of modern dentistry is comprised within the last century, and mainly within its latter half. Beginning with a few practitioners and no organized professional basis, educational system, or literature, its

practitioners are to be found in all civilized communities, those in Great Britain numbering about 5000; in the United States, 27,000; France, 1600, of whom 376 are graduates; German Empire, qualified practitioners (Zahnärzte), 1400; practitioners without official qualification, 4100. Its educational institutions are numerous and well equipped. It possesses a large periodical and standard literature in all languages. Its practice is regulated by legislative enactment in all countries the same as is medical practice. The business of manufacturing and selling dentists' supplies represents an enormous industry, in which millions of capital are invested.

**Denton,** a township in the Gorton division of Lancashire, England, 4½ miles north-east from Stockport, with a station on a branch of the London and North-Western Railway. The township of Haughton was added to it in 1894, and it has since been governed by an urban district council. Public buildings include, besides churches and chapels, the free library, installed in new and spacious premises in 1898, and the Conservative and the Liberal club houses. In the township are reservoirs for the water supply of Manchester, with a capacity of 1860 millions of gallons. The manufacture of felt hats is the leading industry. Coal is extensively mined in the district. The population of the urban district in 1891 was 13,993; in 1901, 14,934.

**Denver,** the capital of the state of Colorado, U.S.A., and county seat of Arapahoe county, situated in lat. 39° 45′ N. and long. 105° W. It comprises an area of 49 square miles on the South Platte river, 15 miles east of the foot of the Rocky Mountains, at a mean elevation of 5280 feet above sea-level. The population in 1890 was 106,713, and in 1900 it was 133,859, of whom 25,301 were foreign-born and 3923 were negroes. Out of 42,712 males of voting age (21 years and over), only 716 were reported by the U.S. census enumerators in 1900 as illiterate (unable to write); of these 548 were foreign-born. The death-rate in 1890 was 23·0; in 1900 it was 18·6. The city is the junction of the Burlington and Missouri River, the Chicago Rock Island and Pacific, the Kansas Pacific, the Missouri Pacific, the Union Pacific, the Atchison, Topeka, and Santa Fe, the Denver and Rio Grande, the Colorado Midland, and the Colorado and Southern Railway systems. The street railways are owned by a private corporation using electrical motive-power. The public education is provided by 3 high schools, a manual training school, and 44 public schools, the total public school property being valued at $2,700,000. According to the census of 1900, the number of persons of school age (5 to 20 years inclusive) was 37,423. The University of Denver, Gross Medical College, and the College of the Sacred Heart are influential institutions. A public library, with 75,000 volumes, is supported by a tax of one-half of one mill upon the assessed valuation of the city, which, for 1900, was $69,550,115 on a basis of about one-third actual value. The city has 12 parks, with a total area of 550 acres. The water supply is derived from mountain streams and carried to the city by gravity. Its daily capacity is 60,000,000 gallons. The factories in 1900 employed an average number of 10,926 wage-earners, with total wages amounting to $6,824,003, the total value of the manufactured products being $41,368,698. The city has four national banks, three savings banks, three State banks, and a branch of the United States mint. In 1858 placer gold was discovered at the junction of Cherry Creek with the South Platte river at 39° 47′ N. lat. and 105° W. long., which led to a small settlement called Auraria. In 1859 Denver (named after General James Denver, then Governor of Kansas Territory) was laid out on the east side of Cherry Creek, and shortly afterwards the two settlements were united. The city is the centre of the wealth and influence of the increasing mineral, agricultural, and stock-raising interests of the Rocky Mountain region. (J. H. PE.)

**Deogarh,** a town of British India, in the Sonthal Parganas district of Bengal. Situated in 24° 29′ N. lat. and 86° 44′ E. lat. Population, about 8000. It is famous for a group of twenty-two temples dedicated to Siva, the resort of numerous pilgrims. It is connected with the East Indian Railway by a steam tramway, 5 miles in length. In 1897 the net earnings were Rs.19,168, yielding a profit of 3·9 per cent. on a capital outlay of Rs.2,87,942.

**Depretis, Agostino** (1813–1887), Italian statesman, was born at Mezzana Corte, in the province of Stradella, 31st January 1813. Before 1848 he conspired with Mazzini, and was nearly captured by the Austrians while smuggling arms into Milan. Elected deputy in 1848, he joined the Left and founded the journal *Il Diritto*, but held no official position until appointed Governor of Brescia in 1859. In 1860 he went to Sicily on a mission to reconcile the policy of Cavour (who desired the immediate incorporation of the island in the kingdom of Italy) with that of Garibaldi, who wished to postpone the Sicilian *plébiscite* until after the liberation of Naples and Rome. Though appointed pro-dictator of Sicily by Garibaldi, he failed in his attempt. Accepting the portfolio of Public Works in the Rattazzi Cabinet in 1862, he served as intermediary in arranging with Garibaldi the expedition which ended disastrously at Aspromonte. Four years later he entered the Ricasoli Cabinet as Minister of Marine, and, by maintaining Admiral Persano in command of the fleet, contributed to the defeat of Lissa. Upon the death of Rattazzi in 1873, Depretis became leader of the Left, prepared the advent of his party to power, and was called upon to form the first Cabinet of the Left in 1876. Overthrown by Cairoli in March 1878 on the grist-tax question, he succeeded, in the following December, in defeating Cairoli, became again Premier, but on 3rd July 1879 was once more overturned by Cairoli. In November 1879 he, however, entered the Cairoli Cabinet as Minister of the Interior, and in May 1881 succeeded to the Premiership, retaining that office until his death on 29th July 1887. During the long interval he recomposed his Cabinet four times, first throwing out Zanardelli and Baccarini in order to please the Right, and subsequently bestowing portfolios upon Ricotti, Robilant, and other Conservatives, so as to complete the political process known as "*trasformismo.*" A few weeks before his death he repented of his transformist policy, and again included Crispi and Zanardelli in his Cabinet. During his long term of office he abolished the grist tax, extended the suffrage, completed the railway system, aided Mancini in forming the Triple Alliance, and initiated colonial policy by the occupation of Massawa; but, at the same time, he vastly increased indirect taxation, corrupted and destroyed the fibre of parliamentary parties, and, by extravagance in public works, impaired the stability of Italian finance. Shrewdness and unscrupulous political

ability assured him a long lease of power, but his influence upon Italian public life has been permanently deleterious.

(H. W. S.)

**Deptford,** a town of England, in the county of London, partly in Kent and partly in Surrey, at the junction of the Ravensbourne with the Thames, 3½ miles east of London Bridge, 5 miles from Charing Cross by rail. The parish of Deptford St Paul has been formed into the new metropolitan borough of Deptford. There are two open spaces, namely, Deptford Park, consisting of the site of the gardens of old Sayes Court (11 acres), and Telegraph Hill (9½ acres). The Trinity House was founded at Deptford, and the old hall was pulled down in 1787. A new building was erected, which was used by the corporation until the Trinity House on Tower Hill was ready for occupation, and occasionally for many years afterwards. The population of Deptford St Nicholas (now included in the metropolitan borough of Greenwich) was (1881), 7901; (1896), 7722; of Deptford St Paul (1881), 76,752; (1901), 110,513.

**Dera Ghazi Khan,** a town and district of British India, in the Derajat division of the Punjab. In 1881 the town had a population of 22,309, and in 1891 of 27,886; the municipal income in 1897–98 was Rs.1,57,532. There are several handsome mosques in the native quarter. The cantonment accommodates one cavalry and two infantry regiments of the Punjab Frontier Force. There is an efficient high school.

The DISTRICT OF DERA GHAZI KHAN contains an area of 5606 square miles. The population in 1891 was 404,031, being 72 persons per square mile, an increase since 1881 of 11 per cent. Classified according to religion, Mahommedans numbered 349,587, largely Baluchis; Hindus, 52,903; Sikhs, 1424; Christians, 117, of whom 73 were Europeans. In 1901 the population was 445,163, showing a further increase of 10 per cent. The total amount of land revenue and rates was returned as Rs.6,83,807, the incidence of assessment being 3 annas per acre; the number of police was 514. In 1896–97, out of a total cultivated area of 443,749 acres, 230,074 were irrigated, mostly from Government canals and wells. The exports are wheat and indigo. The only manufactures are for domestic use. There is no railway in the district, and only 25 miles of metalled road. The Indus, which is nowhere bridged, is navigable by native boats throughout its course of 239 miles. Education is making some progress. There are three Mahommedan institutions and one Hindu for religious instruction. In 1896–97 there were altogether 233 schools, with 5784 pupils, the proportion of boys at school to those of school-going age being 11·9 per cent. The registered death-rate in 1897 was 36 per thousand; the rainfall in 1897 was 5·41 inches.

**Dera Ismail Khan,** a town and district of British India, in the Derajat division of the Punjab. The town is situated near the right bank of the Indus, here crossed by a bridge of boats during half the year. In 1881 it had a population of 22,164, and in 1891 of 26,884; the municipal income in 1897–98 was Rs.54,889. It takes its name from Ismail Khan, a Beluchi chief who settled here towards the end of the 15th century, and whose descendants ruled for 300 years. The old town was swept away by a flood in 1823, and the present town stands 4 miles back from the permanent channel of the river. The native quarters are well laid out, with a large bazaar for Afghan traders. It is the residence of many Mahommedan gentry. The cantonment accommodates a force of all arms. There are several efficient schools, one missionary. A vernacular newspaper is issued. There is considerable through trade with Afghanistan by the Gomal Pass, and there are manufactures of scarves and inlaid wood-work. Here is the tomb of Sir Henry Durand, Lieutenant-Governor of the Punjab.

The DISTRICT OF DERA ISMAIL KHAN contains an area of 9440 square miles. The population in 1891 was 486,201, being 52 persons per square mile—much the lowest density in the province. Since 1881 the increase had been at the rate of 10 per cent. According to religion, Mahommedans numbered 420,189; Hindus, 62,961; Sikhs, 2840; Christians, 204, including 108 Europeans; "others," 7. In 1901 the population was 527,705, showing a further increase of 9 per cent. The total amount of land revenue and rates was returned as Rs.6,02,437, the incidence of assessment being about 1½ annas per assessed acre, but nearly 15 annas per cultivated acre; the number of police was 627. In 1896–97, out of a total cultivated area of 588,413 acres, 159,849 were irrigated from private canals and wells. Wheat and wool are exported. There are manufactures of cotton cloth. The North-Western Railway runs through the Cis-Indus portion of the district for 93 miles. In the other portion there are 108 miles of metalled roads for military purposes. The Indus is navigable by native boats throughout its course of 120 miles within the district. Education is making fair progress, particularly in the English-teaching schools at the towns. In 1896–97 there were altogether 441 schools, attended by 7714 boys. The proportion of boys at recognized schools was 13·5 per cent. of those of school-going age. The death-rate in 1897 was 50 per thousand; the rainfall in 1897 was 9·77 inches.

**Derajat,** the name of a division or commissionership of British India, in the west of the Punjab, consisting of the four districts of Dera Ismail Khan, Dera Ghazi Khan, Bannu, and Muzaffargarh, the last having been recently transferred to it. It contains a total area of 22,315 square miles, and a population (1891) of 1,643,703, being 74 persons per square mile.

**Derbent.** See DAGHESTAN.

**Derby,** the county town and a municipal (extended 1877), parliamentary, and county borough of Derbyshire, England, on the Derwent, 15¾ miles west by south of Nottingham, and 127 miles north-west by north of London. It is the central station of the Midland Railway system. The enlarged parliamentary borough was in 1885 identified with the municipal borough, which was created a county borough in 1888, and is governed by a mayor, 16 aldermen, and 48 councillors. In 1898 the civil parishes within the borough were constituted one parish, though still ecclesiastically distinct. The water-works of the town, costing over £350,000, became in 1880 the property of the corporation. Electric works, lighting the principal streets, were erected in 1893. There are 17 churches, 2 Roman Catholic churches, and over 30 dissenting chapels. Derby school was in 1879 reconstituted as a first grade school. Among recent erections are a free library and museum, an art gallery, a mechanics' institute, a Midland Railway institute, a grand theatre, an infirmary, and an infectious hospital. The Midland Railway storehouses, workshops, and engine and carriage factory employ altogether over 10,000 men. In Little Chester are chemical and steam boiler works. In 1891 there were 3375 engaged in iron and steel manufactures, 1031 in the manufacture of silk, 963 in the making of carriages, and 290 in the manufacture of china and porcelain. There are two daily newspapers. Area, 3450 acres. Population (1881), 81,168; (1891), 94,146; (1901), 105,785.

**Derby,** a city of New Haven county, Connecticut, U.S.A., on the eastern bank of the Housatonic, at the

mouth of the Naugatuck river. It is on the New York, New Haven, and Hartford Railway, and was chartered in 1894. Population (1890), 5969; (1900), 7930 (2635 foreign-born and 159 negroes).

**Derby, Edward Henry Stanley,** 15TH EARL OF (1826–1893), was the eldest son of the fourteenth earl, the "Rupert of Debate." He was educated at Rugby and Trinity College, Cambridge, where he took a high degree and became a member of the society known as "The Apostles." In March 1848 he unsuccessfully contested the borough of Lancaster, and then made a long tour in the West Indies, Canada, and the United States. During his absence he was elected member for King's Lynn, which he represented till October 1869, when he succeeded to the peerage. No one ever prepared himself more assiduously or with a stronger sense of duty for the great position to which his birth had called him. When he took his seat in the House of Commons he wrote to a Rugby friend (the Rev. W. Philpot) to say, half proudly, half in sorrow, that he had put on the armour which he would never be able to take off again until he died; and he kept his word. He took his place, as a matter of course, among the Conservatives, and delivered his maiden speech in May 1850 on the Sugar Duties. Just before, he had made a very brief tour in Jamaica and South America. In 1852 he went to India, and while travelling in that country he was appointed Under-Secretary for Foreign Affairs in his father's first Administration. From the outset of his career he was known to be a most Liberal Conservative, and in 1855 Lord Palmerston offered him the post of Colonial Secretary. He was much tempted by the proposal, and hurried down to Knowsley to consult his father, who called out when he entered the room, "Hallo, Stanley! what brings you here?—Has Dizzy cut his throat, or are you going to be married?" When the object of his sudden appearance had been explained, the Conservative chief received the courteous suggestion of the Prime Minister with anything but favour, and the offer was declined. In his father's second Administration Lord Stanley held, at first, the office of Secretary for the Colonies, but became President of the Board of Control on the resignation of Lord Ellenborough. He had the charge of the India Bill of 1858 in the House of Commons, became the first Secretary of State for India, and left behind him in the India Office an excellent reputation as a man of business. After the revolution in Greece and the disappearance of King Otho, the people most earnestly desired to have Queen Victoria's second son, Prince Alfred, for their king. He declined the honour, and they then took up the idea that the next best thing they could do would be to elect some great and wealthy English noble, not concealing the hope that although they might have to offer him a Civil List he would decline to receive it. Lord Stanley was the prime favourite as an occupant of this bed of thorns, and it has been said that he was actually offered the crown. That, however, is not true; the offer was never formally made. After the fall of the Russell Government in 1866 he became Foreign Secretary in his father's third Administration. He compared his conduct in that great post to that of a man floating down a river and fending off from his vessel, as well as he could, the various obstacles it encountered. He thought that that should be the normal attitude of an English Foreign Minister, and probably under the circumstances of the years (1866–68) it was the right one. He arranged the Collective Guarantee of the Neutrality of Luxemburg in 1867, negotiated a convention about the *Alabama*, which, however, was not ratified, and most wisely refused to take any part in the Cretan troubles. In 1874 he again became Foreign Secretary in Mr Disraeli's Government. He acquiesced in the purchase of the Suez Canal shares, a measure then considered dangerous by many people, but ultimately most successful; he accepted the Andrassy Note, but declined to accede to the Berlin Memorandum. His part in the later phases of the Russo-Turkish struggle has never been fully explained, for with equal wisdom and generosity he declined to gratify public curiosity at the cost of some of his colleagues. A later generation will know better than his contemporaries what were the precise developments of policy which obliged him to resign. He kept himself ready to explain in the House of Lords the course he had taken if those whom he had left challenged him to do so, but from that course they consistently refrained. Already in October 1879 it was clear enough that he had thrown in his lot with the Liberal party, but it was not till March 1880 that he publicly announced this change of allegiance. He did not at first take office in the second Gladstone Government, but became Secretary for the Colonies in December 1882, holding this position till the fall of that Government in the summer of 1885. In 1886 the old Liberal party was run on the rocks and went to pieces. Lord Derby became a Liberal Unionist, and took an active part in the general management of that party, leading it in the House of Lords till 1891, when Lord Hartington became Duke of Devonshire. In 1892 he presided over the Labour Commission, but his health never recovered an attack of influenza which he had in 1891, and he died at Knowsley on 21st April 1893.

During a great part of Lord Derby's life he was deflected from his natural course by the accident of his position as the son of the leading Conservative statesman of the day. From first to last he was at heart a moderate Liberal. After making allowance, however, for this deflecting agency, it must be admitted that in the highest quality of the statesman, "aptness to be right," he was surpassed by none of his contemporaries, or—if by anybody—by Sir George Cornewall Lewis alone. He would have been more at home in a state of things which did not demand from its leading statesman great popular power; he had none of those "isms" and "prisms of fancy" which stood in such good stead some of his rivals. Byron in a famous passage speaks of those

> "Madmen who have made men mad
> By their contagion, conquerors and kings,
> Sophists, bards, statesmen, all unquiet things
> Which stir too strongly the soul's secret springs
> And are themselves the fools to those they fool!"

Lord Derby was emphatically not the kind of statesman mentioned in that passage. He had another defect besides the want of popular power. He was so anxious to arrive at right conclusions that he sometimes turned and turned and turned a subject over till the time for action had passed. One of his best lieutenants said of him in a moment of impatience: "Lord Derby is like the God of Hegel: 'Er setzt sich, er verneint sich, er verneint seine Negation.'" Like many Englishmen, he loved business for its own sake, and more than he knew. That fact must be borne in mind when we remember the answer he gave to a friend who expressed his surprise at his serving so much as chairman of Private Bill Committees. "I do it," he said, "because I come in that way across the great interests of the country better than I otherwise could." His knowledge, acquired both from books and by the ear, was immense, and he took every opportunity of increasing it. He retained his old university habit of taking long walks with a congenial companion, even in London, and although he cared but little for what is commonly known as society—the society of crowded rooms and fragments of sentences—he very much liked conversation. During the many

years in which he was a member of "The Club" he was one of its most assiduous frequenters, and his loss was acknowledged by a formal resolution. His talk was generally grave, but every now and then was lit up by dry humour. The late Lord Arthur Russell once said to him, after he had been buying some property in Southern England: "So you still believe in land, Lord Derby." "Hang it," he replied, "a fellow must believe in something!" It was to the same companion that he said, when, looking one evening for a book at Knowsley and passing his candle along the shelves, he came to the poems of William Morris: "If I had known that he was going to turn Socialist I wouldn't have gone to the expense of binding him in red morocco!" He did an immense deal of work outside politics. He was Lord Rector of the University of Glasgow from 1868 to 1871, and later held the same office in that of Edinburgh. From 1875 to 1893 he was President of the Royal Literary Fund, and attended most closely to his duties then. He succeeded Lord Granville as Chancellor of the University of London in 1891, and remained in that position till his death. He lived much in Lancashire, managed his enormous estates with great skill, and did a great amount of work as a local magnate. He married in 1870 Maria Catharine, daughter of the fifth Earl De la Warr, and widow of the second marquess of Salisbury. The best account of Lord Derby which exists is that which was prefixed by Mr Lecky, who knew him very intimately, to the edition of his speeches outside Parliament, which was published in 1894. Mr Lecky brings out extremely well what almost every page of these two volumes confirms, that he was most strongly attracted by all questions which related to the condition of the mass of the people. He once wrote to Lord Shaftesbury: "We are both public men deeply interested in the condition of the working class, and for my own part I would rather look back on services such as you have performed for that class than receive the highest honours in the employment of the State." (M. G. D.)

**Derbyshire,** a north midland county of England, bounded W. by Stafford and Cheshire, N.W. by Cheshire, N. by York, E. by Nottingham, and S.E. and E. by Leicester.

*Area and Population.*—The area of the ancient and administrative county (including the county borough of Derby), as given in the census returns, is 658,876 acres or 1029 square miles. The population in 1881 was 461,746, and in 1891 was 528,033, of whom 266,011 were males and 262,022 females, the number of persons per square mile being 513, and of acres to a person 1·25. In 1901 the population was 620,196. Since 1891 the administrative area has undergone various alterations. In 1895 the part of the parish of Pinxton in Nottingham, and a part of the parish of Kirkby-in-Ashfield in the same county, were transferred to Derby, and two parts of the parish of Pinxton were transferred from Derby to Nottingham; in the same year part of the parish of Croxall in Derby was transferred to Stafford; and in 1897 the parishes of Nether Seal and Over Seal, part of the parish of Ashby Woulds, and part of the township of Blackfordby were transferred from Leicester to Derby; while the parishes of Appleby, Oakthorp, and Donisthorpe and Willesley, and the townships of Chilcote, Measham, and Shetton-en-le-Fields, were transferred from Derby to Leicester. The area of the registration county is 557,768 acres, with a population in 1891 of 432,414, of which 252,931 were urban and 179,483 rural. Within this area the increase of population between 1881 and 1891 was 11·87 per cent. Between 1881 and 1891 the excess of births over deaths was 63,103, and the increase in resident population 45,878.

The following table gives the number of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898:—

| Year. | Marriages. | Births. | Deaths. | Illegitimate Births. | |
|---|---|---|---|---|---|
| | | | | Males. | Females. |
| 1880 | 2672 | 13,965 | 7250 | 340 | 364 |
| 1890 | 3229 | 13,261 | 7831 | 286 | 294 |
| 1898 | 3725 | 14,802 | 7987 | 352 | 348 |

The number of marriages in 1899 was 3885, of births 14,663, and of deaths 7921.

The following table shows the marriage, birth, and death rates per 1000 of the population, with the percentage of illegitimate births, for a series of years:—

| | 1870–79. | 1880. | 1880–89. | 1890. | 1888–97. | 1898. |
|---|---|---|---|---|---|---|
| Marriage-rate | 16·0 | 13·7 | 13·2 | 13·4 | 15·2 | 15·9 |
| Birth-rate | 37·8 | 36·5 | 33·9 | 30·8 | 32·1 | 31·7 |
| Death-rate | 21·0 | 18·9 | 17·9 | 18·3 | 17·5 | 17·1 |
| Percentage of illegitimate births | 5·4 | 5·0 | 4·8 | 4·4 | 4·4 | 4·7 |

The birth-rate is above the average, but the death-rate rather under it.

The number of Scots in the county in 1891 was 1872, of Irish 4234, and of foreigners 684.

*Constitution and Government.*—The ancient county is divided into seven parliamentary divisions, and it also includes the parliamentary borough of Derby, returning two members. The administrative county includes the municipal boroughs of Chesterfield (27,185), Derby (105,785), Glossop (21,526), and Ilkeston (25,383). Derby is a county borough. The following are urban districts:—Alfreton (17,505), Alvaston and Boulton (4526), Ashbourne (4039), Bakewell (2850), Baslow and Bubnell (797), Belper (10,934), Bolsover (6844), Bonsall (1360), Brampton and Walton (2698), Buxton (10,181), Claycross (8348), Dronfield (3809), Fairfield (2969), Heage (2889), Heanor (16,249), Long Eaton (13,045), Matlock (5980), Matlock Bath (1816), Newbold and Dunston (5986), Newmills (7773), North Darley (2756), Ripley (10,111), South Darley (788), Swadlincote (18,014), Whittington (9416), and Wirksworth (3807). Derbyshire is in the midland circuit, and assizes are held at Derby. The boroughs of Derby, Chesterfield, and Glossop have separate commissions of the peace, and Derby has also a separate court of quarter sessions. The ancient county, which is partly in the dioceses of Lichfield, Peterborough, and Southwell, contains 240 ecclesiastical parishes and districts, and parts of eleven others.

*Education.*—There is a residential college (Lichfield diocesan) for schoolmistresses at Derby, which also takes day students. At Derby there is also a royal institution for the deaf and dumb. The number of elementary schools in the county on 31st August 1899 was 422, of which 117 were board and 305 voluntary schools, the latter including 246 National Church of England schools, 12 Wesleyan, 16 Roman Catholic, and 31 "British and other." The average attendance at board schools was 41,358, and at voluntary schools 53,833. The total school board receipts for the year ended 29th September 1899 were £159,815. The income under the Technical Instruction Act was over £1689; that under the Agricultural Rates Act was over £2943.

*Agriculture.*—About three-fourths of the total area of the county is under cultivation, and of this area as much as four-fifths is under permanent pasture, cattle rearing and dairy farming, including the manufacture of cheese, occupying the chief attention of the farmer. Less than 39,000 acres are in hill pasture, and nearly 26,000 acres are under woods. Wheat and oats are the principal corn crops, and their acreage has within recent years greatly diminished. Turnips occupy more than half the area under green crops. The following table gives the larger main divisions of the cultivated area at intervals of five years from 1880:—

| Year. | Total Area under Cultivation. | Corn Crops. | Green Crops. | Clover. | Permanent Pasture. | Fallow. |
|---|---|---|---|---|---|---|
| 1880 | 512,368 | 63,135 | 21,026 | 28,774 | 388,966 | 10,453 |
| 1885 | 514,660 | 56,293 | 22,081 | 24,889 | 405,680 | 5,717 |
| 1890 | 514,573 | 53,297 | 20,144 | 25,947 | 410,320 | 4,460 |
| 1895 | 503,185 | 48,498 | 19,714 | 25,093 | 406,487 | 2,822 |
| 1900 | 494,716 | 46,923 | 18,169 | 24,697 | 401,830 | 2,541 |

The following table gives particulars regarding the principal live stock for the same years:—

| Year. | Total Horses. | Total Cattle. | Cows or Heifers in Milk or in Calf. | Sheep. | Pigs. |
|---|---|---|---|---|---|
| 1880 | 21,847 | 134,786 | 64,324 | 228,445 | 29,704 |
| 1885 | 21,631 | 155,308 | 73,888 | 204,925 | 35,143 |
| 1890 | 22,357 | 143,232 | 71,186 | 202,897 | 36,190 |
| 1895 | 27,105 | 136,111 | 68,806 | 176,998 | 40,919 |
| 1900 | 26,722 | 143,609 | 70,723 | 171,364 | 34,108 |

*Manufactures and Minerals.*—According to the report for 1898 of the chief inspector of factories (issued 1900) the total number of persons employed in factories and workshops in 1897 was 67,848, as compared with 68,774 in 1896. Of these nearly a third (20,324)

were employed in textile factories, there being an increase between 1895 and 1896 of 10·4 per cent., but a decrease between 1896 and 1897 of 8·4 per cent. About one-half (10,701) were employed in the cotton industry, while lace employed 4667, hosiery (chiefly cotton and silk) 2530, and silk 1092. Non-textile factories employed 43,630 persons, there being an increase between 1895 and 1896 of 13·9 per cent., and between 1896 and 1897 of 2·9 per cent. Those employed in the manufacture of machines, appliances, conveyances, and tools numbered 13,990; the founding and conversion of metals employed 10,027; the making of earthenware, etc., 3884; print (calico), bleach, and dye works, 3813; and papermaking, printing, &c., 3186. In workshops only 3894 persons were employed, the majority (2263) in the clothing industries. The total number of persons employed in mining in 1899 was 48,578. In its limestone production the county stands next to Durham, the amount raised in 1899 being 1,761,270 tons. In the same year 519,208 tons of clay were raised, including 71,244 tons of fireclay valued at £21,373 (the total value of the clays being £43,648), 165,366 tons of sandstone, and 30,218 tons of gravel and sand. But the principal mineral is coal. Ironstone is not extensively wrought, but on account of the abundant supply of coal, large quantities are imported for smelting purposes. The amount of pig-iron produced in 1885 was 368,863 tons, in 1890, 387,760 tons, in 1895, 413,454 tons, and in 1899 (including Nottingham, the production in which county is, however, small) 511,994 tons. The furnaces are situated in Alfreton, Chesterfield, Derby, and Ilkeston. Zinc is mined to a small extent. The following table gives particulars regarding the production of coal, gypsum, iron ore, and lead in 1890 and 1898:—

| Year. | Coal. | | Gypsum. | | Iron Ore. | | Lead. | |
|---|---|---|---|---|---|---|---|---|
| | Tons. | Value. | Tons. | Value. | Tons. | Value. | Tons. | Value. |
| | | £ | | £ | | £ | | £ |
| 1890 | 10,445,974 | 4,705,188 | 67,571 | 30,407 | 23,732 | 8306 | 4026 | 30,195 |
| 1899 | 14,594,424 | 5,047,238 | 11,557 | 5,778 | 3,526 | 1534 | 4266 | 31,995 |

**Dereham** (East), a market town and railway station in the Mid parliamentary division of Norfolk, England, 15 miles west by north of Norwich. The ancient church of St Nicholas contains interesting memorials, and the Congregational chapel stands on the site of the house where the poet Cowper spent his last days. Dereham is an important agricultural centre with works for agricultural implements. Area of civil parish (an urban district), 5313 acres; population (1881), 5640; (1901), 5545.

**Déroulède, Paul** (1846-——), French author and politician, was born in Paris on 2nd September 1846. He made his first appearance as a poet in the pages of the *Revue nationale*, under the pseudonym of Jean Rebel, and in 1869 produced at the Théâtre Français a one-act drama in verse entitled *Juan Strenner*. On the outbreak of the Franco-German war he enlisted as a private, was wounded and taken prisoner at Sedan, and sent to Breslau, but effected his escape. He then served under Chanzy and Bourbaki, took part in the latter's disastrous retreat to Switzerland, and fought against the Commune in Paris. After attaining the rank of lieutenant, he was forced by an accident to retire from the army. He now published a number of patriotic poems (*Chants du soldat*), which enjoyed unbounded popularity. In 1877 he produced a drama in verse called *L'Hetman*, which derived a passing success from the patriotic fervour of its sentiments. For the Exhibition of 1878 he wrote a hymn, *Vive la France*, which was set to music by Gounod. In 1879 his drama in verse, *La Moabite*, which had been accepted by the Théâtre Français, was forbidden by the censor on religious grounds. In 1882 M. Déroulède founded the *Ligue des Patriotes*, with the object of furthering France's "revanche" against Germany. He was one of the first advocates of a Franco-Russian alliance, and as early as 1883 undertook a journey to Russia for the furtherance of that object. On the rise of General Boulanger, M. Déroulède attempted to use the *Ligue des Patriotes*, hitherto a non-political organization, to assist his cause, but was deserted by a great part of the League and forced to resign his presidency. Nevertheless he used the section of the League that remained faithful to him with such effect that the Government found it necessary in 1889 to decree its suppression. In the same year he was elected to the Chamber as member for Angoulême. He did not stand at the elections of 1893, but was re-elected in 1898, and distinguished himself by his violence as a Nationalist and anti-Dreyfusard. After the funeral of President Faure, on 23rd February 1899, he endeavoured to persuade General Roget to lead his troops upon the Elysée. For this he was arrested, but on being tried for treason was acquitted (31st May). On 12th August he was again arrested and accused, together with André Buffet, Jules Guérin, and others, of conspiracy against the Republic. After a long trial before the High Court, he was sentenced, on 4th January 1900, to ten years' banishment from France, and retired to San Sebastian. In 1901 he was again brought prominently before the public by a quarrel with his Royalist allies, which resulted in an abortive attempt to arrange a duel with M. Buffet in Switzerland. Besides the works already mentioned, he has published *Le Sergent*, in the "Théâtre de campagne" (1880); *De l'éducation nationale* (1882); *Monsieur le Uhlan et les trois couleurs* (1884); *Le premier grenadier de France, La Tour d'Auvergne* (1886); *Refrains militaires* (1889); *Histoire d'amour* (1890); a pamphlet entitled *Désarmement?* (1891); *Poésies militaires* and *Messire du Guesclin, Drame en vers* (1896); *La Mort de Hoche. Cinq actes en prose* (1897); *La plus belle fille du monde, conte dialogué en vers libres* (1898).

**Des Moines,** capital and largest city of Iowa, U.S.A., and capital of Polk county, in 41° 36′ N. lat. and 93° 38′ W. long., on Des Moines river, at an altitude of 800 feet. It has a regular street plan, is supplied with water from the Raccoon river, a branch of the Des Moines, by the Holly pumping system, its streets are partly paved with brick, and it is divided into seven wards. Among the fine buildings are the new State Capitol, erected at a cost of $3,000,000, the United States Post Office, the City Hall, and the Grand Opera House. There are two public libraries, the larger of which, the State Library, contains 46,000 volumes. There are two institutions for higher education, Drake University and Des Moines College. The former under the Christian denomination had, in 1899, 54 instructors and 722 students; the latter, 10 instructors and 157 students. Des Moines is an important railway centre. It is the meeting-point of five great systems, the Chicago, Burlington, and Quincy, the Chicago and North-Western, the Chicago Great Western, the Chicago, Rock Island, and Pacific, and the Wabash, which give it a large commerce. In 1900 there were 494 manufacturing establishments, with a capital of $7,911,764, with 4557 hands, and a product valued at $10,488,189. The assessed valuation of property, real and personal, was, in 1900, $13,871,430; the net debt (exclusive of school debt) was $727,777, and the tax rate (exclusive of school tax) $42.40 per $1000. The basis of assessment is very low (about one-fourth of full value). Population (1890), 50,093; (1900), 62,139, of whom 7946 were foreign-born and 1675 negroes.

**Desoto,** a city of Jefferson county, Missouri, U.S.A.,

on the St. Louis, Iron Mountain, and Southern Railway. Population (1890), 3960; (1900), 5611, of whom 332 were foreign-born and 364 negroes.

**Dessau,** a town of Germany, capital of duchy of Anhalt, 2 miles south of the Elbe and 38 miles by rail south-east from Magdeburg. A new town hall was built in 1899–1900. Other new buildings are St Paul's church (1890–92), a Roman Catholic church, the "magistrates' house" (1872–1874), containing a library and drawings by Dürer, Holbein, Cranach, and State law courts; there are monuments to Moses Mendelssohn (1890), the Emperor William I. (1892), W. Müller (1891), who was a native of Dessau, and a war monument (1874). There are a small ducal library, a geological collection, the Leopold home for impoverished men (1750), and a picture gallery in the Amelia Institute. The various industries produce sugar, cloth, machinery, woollen yarn, carpets, blinds; iron-founding and gardening are also carried on; an important corn market. Population (1885), 27,766; (1895), 42,375; (1900), 50,677.

**Desterro.** See Florianopolis.

**Destructors.**—The name destructors is applied by English municipal engineers to furnaces, or combinations of furnaces, constructed for the purpose of disposing by burning of town refuse, which is a heterogeneous mass of material, including, besides general household and ash-bin refuse, small quantities of garden refuse, trade refuse, market refuse, and often street sweepings. The mere disposal of this material is not, however, by any means the only consideration in dealing with it upon the destructor system. For many years past scientific experts, municipal engineers, and public authorities have been directing careful attention to the utilization of refuse as fuel for steam production, and such progress in this direction has been made of late that in many towns its calorific value is now being utilized daily in operating machinery. On the other hand, that proper degree of caution which is obtained only by actual experience must be exercised in the application of refuse fuel to steam-raising purposes. When its value as a low-class fuel was first recognized, the idea was disseminated that the refuse of a given population was of itself sufficient to develop the necessary steam-power for supplying that population with the electric light. The economical importance of a combined destructor and electric undertaking of this character naturally presented a somewhat fascinating stimulus to public authorities, and possibly has had much to do with the recent development both of the adoption of the principle of dealing with refuse by fire, and also of lighting towns by electricity. However true this phase of the question may be as the statement of a theoretical scientific fact, experience so far does not show it to be a basis upon which engineers may venture to calculate, although, as will be seen later, under certain circumstances of equalized load, which must be considered upon their merits in each case, a well-designed destructor plant can be made to perform valuable commercial service to an electric or other power-using undertaking. Further, when a system, thermal or otherwise, for the storage of energy can be introduced and applied in a trustworthy and economical manner, the degree of advantage to be derived from the utilization of the waste heat from destructors will be materially enhanced.

***Composition of refuse.***

The composition of house refuse, which must obviously affect its calorific value, varies considerably in different localities, according to the condition, habits, and pursuits of the people. From analyses it is found that average London ash-bin refuse contains the constituents in the average proportions given in the following table. In the northern towns, where the privy and ash-pit system is in use, excrementitious matter also occurs in the refuse.

| Average London Ash-bin Refuse. | | Manchester Refuse. | |
|---|---|---|---|
| Constituents. | Percentages by Weight. | Constituents. | Percentages by Weight. |
| Breeze (cinder and ashes) | 63·69 | Ashes and excreta in pails | 64·50 |
| Fine dust | 19·51 | Dust and cinders | 34·55 |
| Vegetable, animal, and various mineral matters | 4·61 | Fish and bones | ·15 |
| Waste paper | 4·28 | Animal refuse, as dogs, cats, hens, rabbits, &c. | ·05 |
| Straw, fibrous material, and rags | 3·61 | Boots, hats, rags, paper, &c. | ·05 |
| Bottles, crockery, and broken glass | 1·98 | Vegetable refuse | ·05 |
| Coal and coke | ·84 | Glass, pottery, bricks, &c. | ·60 |
| Tins and iron | 1·00 | Old iron and tin ware | ·05 |
| Bones | ·48 | | |
| Total | 100·00 | Total | 100·00 |

In London the quantity of house refuse amounts approximately to $1\frac{1}{4}$ million tons per annum, which is equivalent to from 4 cwt. to 5 cwt. per head per annum, or to from 200 to 250 tons per 1000 of the population per annum. Statistics, however, vary widely in different districts. In the vicinity of the metropolis the amount varies from 2·5 cwt. per head per annum at Leyton to 3·5 cwt. at Hornsey, and to as much as 7 cwt. at Ealing. In the north of England the total house refuse collected, exclusive of street sweepings, amounts on the average to 8 cwt. per head per annum. Speaking generally, throughout the country an amount of from 5 cwt. to 10 cwt. per head per annum should be allowed for. A cubic yard of ordinary house refuse weighs from $12\frac{1}{4}$ to 15 cwt. Shop refuse is lighter, frequently containing a large proportion of paper, straw, and other light wastes. It sometimes weighs as little as $7\frac{1}{4}$ cwt. per cubic yard. A load, by which refuse is often estimated, varies in weight from 15 cwt. to $1\frac{1}{2}$ tons.

***Disposal.***

The question how a town's refuse shall be disposed of must be considered both from a commercial and a sanitary point of view. Various methods have been practised. Sometimes the household ashes, &c., are mixed with pail excreta, or with sludge from a sewage farm, or with lime, and disposed of for agricultural purposes, and sometimes they are conveyed in carts or by canal to outlying and country districts, where they are shot on waste ground or used to fill up hollows and raise the level of marsh land. Such plans are economical when suitable outlets are available. To take the refuse out to sea in hopper barges and sink it in deep water, as is done, for example, at Liverpool and New York, is usually expensive and frequently unsatisfactory. At Bermondsey, for instance, the cost of barging is about 2s. 9d. a ton, while the material may be destroyed by fire at a cost of from 10d. to 1s. a ton, exclusive of interest and sinking fund on the cost of the works. In other cases, as at Chelsea and various dust contractors' yards, the refuse is sorted and its ingredients are sold; the fine dust may be utilized in connexion with manure manufactories, the pots and pans employed in forming the foundations of roads, and the cinders and vegetable refuse burnt to generate steam. In the Arnold system, carried out in Philadelphia and other American towns, the refuse is sterilized by steam under pressure, the grease and fertilizing substances being extracted at the same time; while in other systems, such as those of Weil and Porno, and of Defosse, distillation in closed vessels is practised. But the destructor system, in which the refuse is burned to an innocuous clinker in specially constructed furnaces, is that which must finally be resorted to, especially in districts which have become well built up and thickly populated. Various types of furnaces and apparatus have from time to time been designed, and the subject has been one of much experiment and many failures.

***Destructors.***

The principal towns in England which took the lead in the adoption of the refuse destructor system were Manchester, Birmingham, Leeds, Heckmondwike, Warrington, Blackburn, Bradford, Bury, Bolton, Hull, Nottingham, Salford, Ealing, and London. Ordinary furnaces, built mostly by dust contractors, were in use in London and in the north of England some forty years ago, but they were not scientifically adapted to the purpose, and necessitated the admixture of coal or other fuel with the refuse to ensure its cremation. The Manchester Corporation erected a furnace of this description about the year 1873, and Messrs Mead and Co. made an unsatisfactory attempt in 1870 to burn house refuse in closed furnaces at Paddington. In 1876 Mr Fryer erected his destructor at Manchester, and several other towns adopted this furnace shortly afterwards. Other furnaces were from time to time brought before the public, among which may be mentioned those of Pearce and Lupton, Pickard,

Healey, Thwaite, Young, Wilkinson, Burton, Hardie, Jacobs and Odgen. In addition to these the "Beehive" and the "Nelson" destructors became well known. The former was introduced by Stafford and Pearson of Burnley, and one was erected in 1884 in the parish yard at Richmond, Surrey, but the results being unsatisfactory, it was closed during the following year. The "Nelson" furnace, patented in 1885 by Messrs Richmond and Birtwistle, was erected at Nelson-in-Marsden, Lancashire, but being very costly in working, was abandoned. The principal types of destructors now in use are those of Fryer, Whiley, Horsfall, Warner, Meldrum, and Beaman and Deas.

***Fryer's.***

The general arrangement of the destructor patented[1] by Mr Alfred Fryer in 1876 is illustrated in Fig. 1. An installation upon this principle consists of a number of furnaces or cells, usually arranged in pairs back to back, and enclosed in a rectangular block of brickwork having a flat top, upon which the house refuse is tipped from the carts. Each cell measures internally

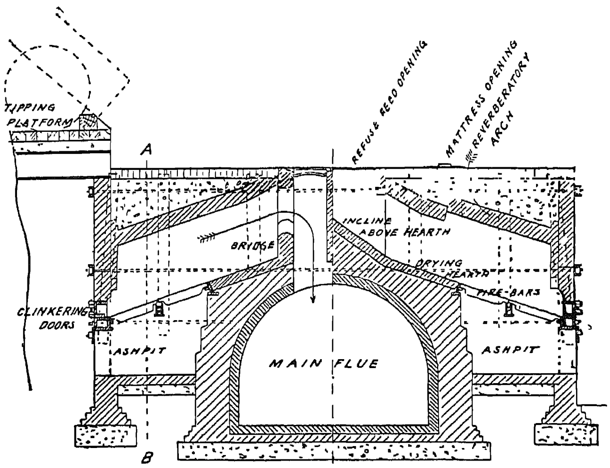

Fig. 1.—Fryer's Destructor.

about 9 feet by 5 feet, and is covered by a firebrick arch 3 feet 6 inches high above the grates. The furnaces have cast-iron furnace mouths, with doors 5 feet wide hinged at the top to open outwards with balance weights. The furnace bottom has an inclination of 1 in 3, from front to back, the rearmost portion, for a width of 4 feet, forming a firebrick hearth or dead plate, and the lower part, having a width of 5 feet, consisting of fire-bars. A wall at the back end of the cells divides each furnace into halves. On one side is a passage forming an opening into the main flue for the escape of the products of combustion, whilst on the other the upper end of the slope is carried up with a steeper inclination to a "feeding hole" for the admission of refuse from the platform above. A large main flue, which also forms the dust chamber, is placed underneath the furnace hearths. The Fryer furnace ordinarily burns from 4 to 6 tons of refuse per cell per 24 hours. It will be observed that the outlets for the products of combustion are placed at the back near the refuse feed opening, an arrangement which is imperfect in design, inasmuch as while a charge of refuse is burning upon the furnace bars the charge which is to follow lies on the dead hearth near the outlet flue. Here it undergoes drying and partial decomposition, giving off offensive empyreumatic vapours which pass into the flue without being exposed to sufficient heat to render them entirely inoffensive. The serious nuisances thus produced in some instances led to the introduction of a second furnace, or "cremator," patented by Mr C. Jones of Ealing in 1885, which was placed in the main flue leading to the chimney-shaft, for the purpose of resolving the organic matters present in the vapour, but the greatly increased cost of burning due to this device led to its abandonment in many cases. This type of cell was largely used during the early period of the history of destructors, but of recent years has to a considerable extent given place to furnaces of more modern design.

***Whiley's.***

A furnace patented[2] in 1891, by Mr Henry Whiley, superintendent of the scavenging department of the Manchester Corporation, is automatic in its action and has been designed primarily with a view to saving labour—the cells being fed, stoked, and clinkered automatically. There is no drying hearth, and the refuse carts tip direct into a shoot or hopper at the back which conducts the material directly on to movable eccentric grate bars. These automatically traverse the material forward into the furnace, and finally push it against a flap-door which opens and allows it to fall out. This apparatus is adapted for dealing with screened rather than unscreened refuse, since it suffers from the objection that the motion of the bars tends to allow fine particles to drop through unburnt. Some difficulty has been experienced from the refuse sticking in the hopper, and exception may also be taken to the continual flapping of the door when the clinker passes out, as cold air is thereby admitted into the furnace. As in the Fryer cell, the outlet for the products of combustion into the main flue is close to the point where the crude refuse is fed into the furnace, and the escape of unburnt vapours is thus facilitated. Forced draught is applied by means of a Root's blower. The Manchester Corporation has 28 cells of this type in use, and the approximate amount of refuse burnt per cell per 24 hours is from 6 to 8 tons at a cost per ton for labour of 3·47 pence.

***Horsfall's.***

Horsfall's destructor[3] (Fig. 2) is a high-temperature furnace of modern type which has been adopted largely in Great Britain and on the continent of Europe. In it some of the general features of the Fryer cell are retained, but the details differ considerably from those of the furnaces already described. Important points in the design are the arrangement

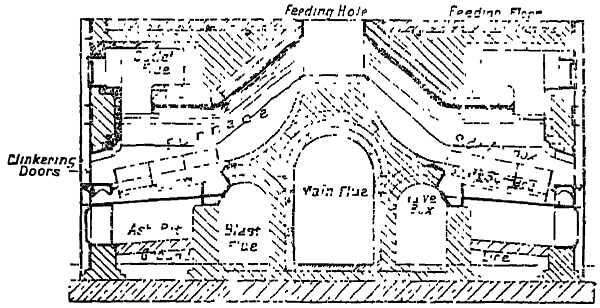

Fig. 2 Horsfall's Improved Destructor.

of the flues and flue outlets for the products of combustion, and the introduction of a blast duct through which air is forced into a closed ash-pit. The feeding-hole is situated at the back of and above the furnace, while the flue opening for the emission of the gaseous products is placed at the front of the furnace over the dead plate; thus the gases distilled from the raw refuse are caused to pass on their way to the main flue over the hottest part of the furnace and through the flue opening in the red-hot reverberatory arch. The steam jet, which plays an important part in the Horsfall furnace, forces air into the closed ash-pit at a pressure of about $\frac{3}{4}$ to 1 inch of water, and in this way a temperature varying from 1500° to 1900° F., as tested by a thermo-electric pyrometer, is maintained in the main flue. In a battery of cells the gases from each are delivered into one main flue, so that a uniform temperature is maintained therein sufficiently high to prevent noxious vapours from reaching the chimney. The cells being charged and clinkered in rotation, when the fire in one is green, in the others it is at its hottest, and the products of combustion do not reach the boiler surfaces until after they have been mixed in the main flue. The cast-iron boxes which are provided at the sides of the furnaces, and through which the blast air is conveyed on its way to the grate, prevent the adhesion of clinker to the side walls of the cells, and very materially preserve the brickwork, which otherwise becomes damaged by the tools used to remove the clinker. The wide clinkering doors are suspended by counterbalance weights and open vertically. The rate of working of these cells varies from 8 tons per cell per 24 hours at Oldham to 10 tons per cell at Bradford, where the furnaces are of the latest type. The cost of labour in stoking and clinkering is about 6d. per ton of the refuse treated at Bradford, and 9d. per ton at Oldham, where the rate of wages is higher. Well-constructed and properly-worked plants of this type should give rise to no nuisance, and may be located in populous neighbourhoods without danger to the public health or comfort.

***Warner's.***

Warner's destructor,[4] known as the "Perfectus," is, in general arrangement, similar to Fryer's, but differs in being provided with special charging hoppers, dampers in flues, dust-catching arrangements, rocking grate bars and other improvements. The refuse is tipped into feeding-hoppers, consisting of rectangular cast-iron boxes over which plates are placed to prevent the escape of smoke and fumes. At the lower portion of the feeding-hopper is a flap-door working on an axis and controlled by an iron lever from the tipping platform. When refuse is to be fed into the furnace the lever is thrown over, the contents of the hopper drop on to the sloping firebrick hearth beneath, and the door is at once closed again. The door should

[1] Patent No. 3125 (1876).
[2] Patent No. 8271 (1891).
[3] Patent No. 8999 (1887); No. 14,709 (1888); No. 22,531 (1891).
[4] Patent No. 18,719 (1888).

be kept open as short a time as possible in order to prevent the admission of cold air into the furnace at the back end, since this leads to the lowering of the temperature of the cells and main flue, and also to paper and other light refuse being carried into the flues and chimney. The flues of each furnace are provided with dampers, which are closed during the process of clinkering in order to keep up the heat. The cells are each 5 feet wide and 11 feet deep, the rearmost portion consisting of a firebrick drying hearth, and the front of rocking grate bars upon which the combustion takes place. The crown of each cell is formed of a reverberatory firebrick arch having openings for the emission of the products of combustion. The flap dampers which are fitted to these openings are operated by horizontal spindles passing through the brickwork to the front of the cell, where they are provided with levers or handles; thus each cell can be worked independently of the others. With the view of increasing the steam-raising capabilities of the furnace, forced draught is sometimes applied and a tubular boiler is placed close to the cells. The amount of refuse consumed varies from 5 tons to 8 tons per cell per 24 hours. At Hornsey, where 12 cells of this type are in use, the cost of labour for burning the refuse is 9½d. per ton.

**Meldrum's.**

The Meldrum "Simplex" destructor (Fig. 3), a modern type of furnace which yields good steam-raising results, is in successful operation at Rochdale, Hereford, and Darwen, at each of which towns the production of steam is an important consideration. Cells have also been laid down at Burton, Hunstanton, Blackburn, and Shipley. In general arrangement the destructor differs considerably from those previously described. The grates are placed side by side without separation except by dead plates, but, in order to localize the forced draught, the ash-pit is divided into parts corresponding with the different grate areas. Each ash-pit is closed air-tight by a cast-iron plate, and is provided with an air-tight door for removing the fine ash. Two patent Meldrum steam-jet blowers are provided for each furnace, supplying any required pressure of blast up to 6 inches' water column, though that usually employed does not exceed 1½ inches. The furnaces are designed for hand-feeding from the front, but hopper-feeding can be applied if desirable. The products of combustion either pass away from the back of each fire-grate into a common flue leading to boilers and the chimney-shaft, or are conveyed sideways over the various grates and a common fire-bridge to the boilers or chimney. The heat in the gases, after passing the boilers, is still further utilized to heat the air supplied to the furnaces, the gases being passed through an air heater or continuous regenerator consisting of a number of cast-iron pipes from which the air is delivered through the Meldrum "blowers" at a temperature of about 300° F. That a high percentage (15 to 18 per cent.) of $CO_2$ is obtained in the furnaces proves a small excess of free oxygen, and no doubt explains the high fuel efficiency obtained by this type of destructor. High-pressure boilers of ample capacity are provided for the accumulation during periods of light load of a reserve of steam, the storage being obtained by utilizing the difference between the highest and

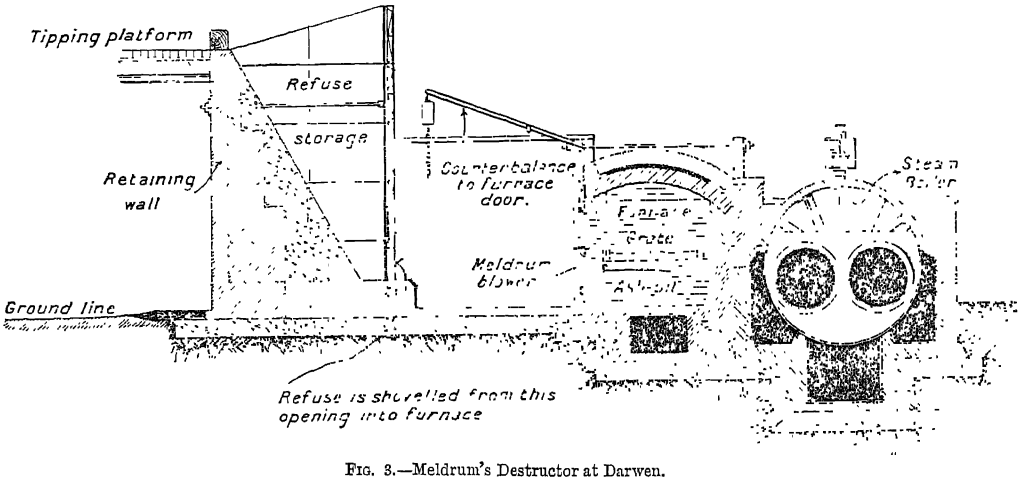

Fig. 3.—Meldrum's Destructor at Darwen.

lowest water-levels and the difference between the maximum and working steam-pressure. Patent locking fire-bars, to prevent lifting when clinkering, are used in the furnace and have a good life. At Rochdale the Meldrum furnaces consume from 53 to 66 lbs. of refuse per square foot of grate area per hour, as compared with 22·4 ℔ per square foot in a low-temperature destructor burning 6 tons per cell per 24 hours with a grate area of 25 square feet. The evaporative efficiency of the Rochdale furnaces varies from 1·39 ℔ to 1·87 ℔ of water (actual) per 1 ℔ of refuse burned, and an average steam-pressure of about 114 ℔ per square inch is maintained. The cost of labour and supervision amounts to 10d. per ton of refuse dealt with. A Lancashire boiler (22 feet by 6 feet 6 inches) at the Sewage Outfall Works, Hereford, evaporates with refuse fuel 2980 ℔ of water per hour, equal to 149 indicated horse-power. About 54 ℔ of refuse are burnt per square foot of grate area per hour with an evaporation of 1·82 ℔ of water per pound of refuse. At Darwen a Meldrum furnace of 104·5 square feet grate area runs the present electric plant consisting of two 150 kilowatt steam dynamos (225 horse-power each), one only being in use at a time. As the dynamos run only 9½ hours per day, while the refuse is burned throughout the 24 hours, there is a large surplus of heat running to waste. This it is proposed to employ for electric tramways and then the available power will be utilized to its full extent.

**Beaman and Deas.**

The Beaman and Deas destructor[1] (Fig. 4) has attracted much attention from public authorities, and successful installations are in operation at Warrington, Dewsbury, Leyton, Canterbury, Llandudno, Colne, Streatham, Rotherhithe, and Wimbledon. Its essential features include a level fire-grate with ordinary type bars, a high-temperature combustion chamber at the back of the cells, a closed ash-pit with forced draught, provision for the admission of a secondary air-supply at the fire-bridge, and a firebrick hearth sloping at an angle of about 52°. From the refuse storage platform the material is fed into a hopper mouth about 18 inches square, and slides down the firebrick hearth, supported by T-irons, to the grate bars, over which it is raked and spread with

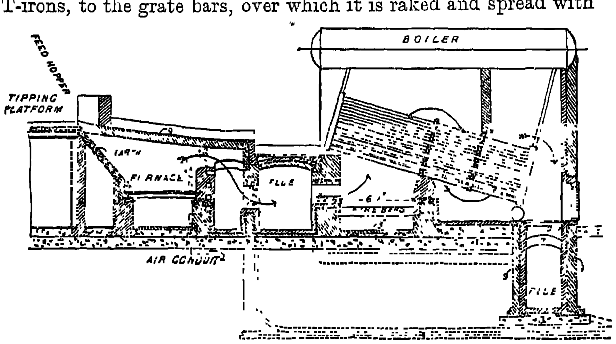

Fig. 4.—Beaman and Deas Destructor at Leyton.

the assistance of long rods manipulated through clinkering doors placed at the sides of the cells. A secondary door in the rear of the cell facilitates the operation. The fire-bars, spaced only $\frac{3}{32}$ inch apart, are of the ordinary stationary type. Vertically, under the fire-bridge, is an air-conduit, from the top of which lead air blast pipes 12 inches in diameter discharging into a hermetically closed ash-pit under the grate area. The air is supplied from fans (Schiele's patent) at a pressure of from 1½ to 2 inches of water, and is controlled by means of baffle valves worked by handles on either side of the furnace, conveniently placed for the attendant. The forced draught tends to keep the bars cool and lessen wear and tear. The fumes from the charge

[1] Patents No. 15,598 (1893) and 23,712 (1893); also Beaman and Deas Sludge Furnace, patent No. 13,029 (1894).

drying on the hearth pass through the fire and over the red-hot fire-bridge, which is perforated longitudinally with air-passages connected with a small flue leading from a grated opening on the face of the brickwork outside; in this way an auxiliary supply of heated oxygen is fed into the combustion chamber. This chamber, in which a temperature approaching 2000° F. is attained, is fitted with large iron doors, sliding with balance weights, which allow the introduction of infected articles, bad meat, etc., and also give access for the periodical removal of fine ash from the flues. The high temperatures attained are utilized by installing one boiler, preferably of the Babcock and Wilcox water-tube type, for each pair of cells, so that the gases, on their way from the combustion chamber to the main flue, pass three times between the boiler tubes. A secondary furnace is provided under the boiler for raising steam by coal, if required, when the cells are out of use. The grate area of each cell is 25 square feet, and the consumption varies from 16 up to 20 tons of refuse per cell per 24 hours. In a 24-hours' test made by the superintendent of the cleansing department, Leeds, at the Warrington installation, the quantity of water evaporated per pound of refuse was 1·14 ℔, the average temperature in the combustion chamber 2000° F. by copper-wire test, and the average air pressure with forced draught, 2½ inches (water gauge). At Leyton, which has a population of over 100,000, an eight-cell plant of this type is successfully dealing with house refuse and filter press cakes of sewage sludge from the Sewage Disposal Works adjoining, and even with material of this low calorific value the total steam-power produced is considerable. Each cell burns about 16 tons of the mixture in 24 hours and develops about 35 indicated horse-power continuously, at an average steam-pressure in the boilers of 105 ℔. The cost of labour at Leyton for burning the mixed refuse is about 1s. 7d. per ton; at Llandudno, where four cells were laid down in connexion with the electric-light station in 1898, it is 1s. 3¼d., and at Warrington, 9½d. per ton of refuse consumed. Combustion is complete, and the destructor may be safely installed in populous districts without nuisance to the inhabitants. Further patents (Wilkie's improvements) have been obtained by Meldrum Brothers (Manchester) in connexion with this destructor.

In addition to the above-described destructors, other modern

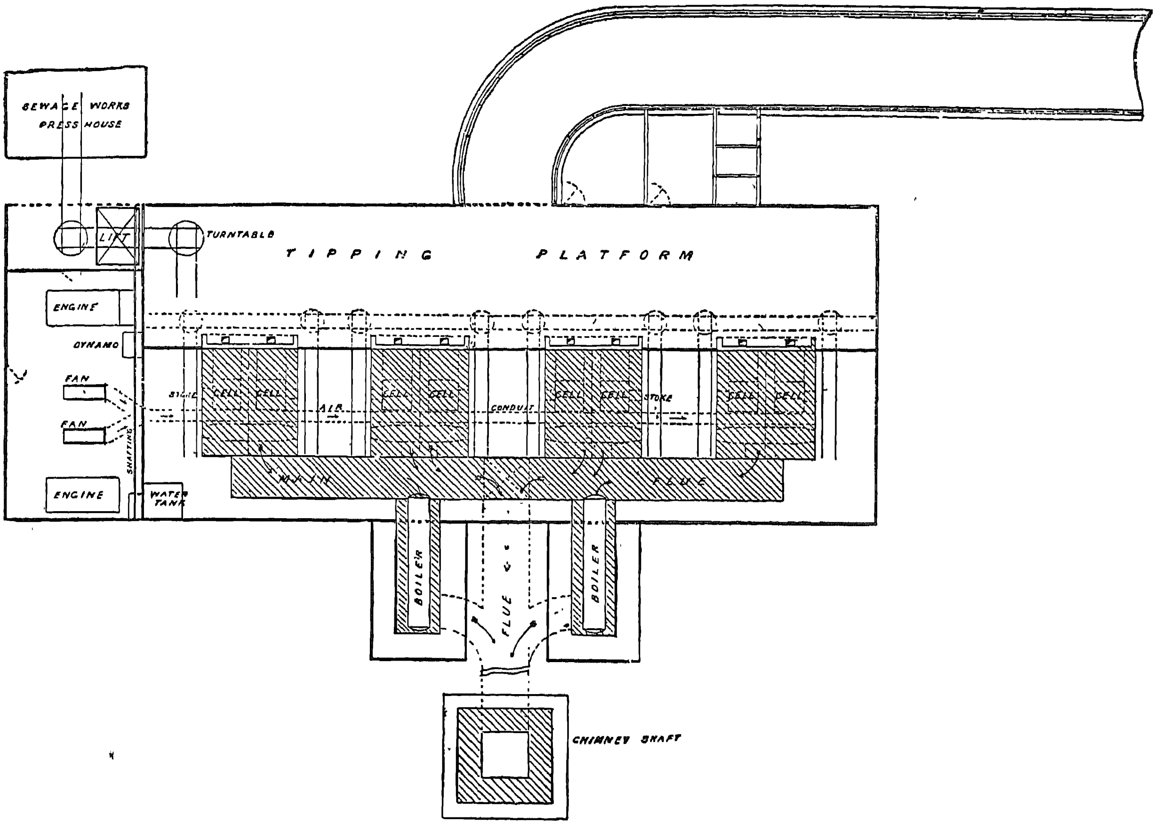

Fig. 5.—Leyton Destructor—Block Plan, showing general arrangement of the works

forms have been introduced from time to time, but adopted to a less degree; amongst these may be mentioned Hanson's Utilizer, Mason's Gasifier, the "Bennett-Phythian," Cracknell's (Melbourne, Victoria), Coltman's (Loughborough), Willoughby's, and Healey's improved destructors. On the continent of Europe, systems for the treatment of refuse have also been devised. Among these may be mentioned those of M. Defosse and M. Helouis. The former has endeavoured to burn the refuse in large quantities by using a forced draught and only washing the smoke.[1] Helouis has extended the operation by using the heat from the combustion of the refuse for drying and distilling the material which is brought gradually on to the grate.

**Destructor accessories.**

Boulnois and Brodie's improved charging tank is a labour-saving apparatus consisting of a wrought-iron truck, 5 ft. wide by 3 ft. deep, and of sufficient length to hold not less than 12 hours' supply for the two cells which it serves. The truck, which moves along a pair of rails laid across the top of the destructor, may be worked by one man. It is divided into compartments holding a charge of refuse in each, and is provided with a pair of doors in the bottom, opening downwards, which are supported by a series of small wheels running on a central rail. A special feeding opening in the reverberatory arch of the cell of the width of the truck, situated over the drying hearth, is formed by a firebrick arch fitted into a frame capable of being moved backwards and forwards by means of a lever. The charging truck, when empty, is brought under the tipping platform, and the carts tip directly into it. When one of the cells has to be fed, the truck is moved along, so that one of the divisions is immediately over the feeding opening, and the wheel holding up the bottom doors rests upon the central rail, which is continued over the movable covering arch. Then the movable arch is rolled back, the doors are released, and the contents are discharged into the cell, so that no handling of the refuse is required from tipping to feeding. This apparatus is in operation at Liverpool, Shoreditch, Cambridge, and elsewhere.

Various forms of patent movable fire-bars have been employed in destructor furnaces. Among these may be mentioned Settle's,[2] Vicar's,[3] Riddle's rocking bars,[4] Horsfall's self-feeding apparatus,[5] and Healey's movable bars;[6] but complicated movable arrangements are not to be recommended, and experience greatly favours the use of a simple stationary type of fire-bar.

[6] Patents No. 18,398 (1892) and No. 12,990 (1892).

A dust-catching apparatus has been designed and erected at Edinburgh, by the Horsfall Furnace Syndicate, in order to overcome difficulties in regard to the escape of flue dust, &c., from the destructor chimney. Externally, it appears a large circular block of brickwork, 18 ft. in diameter and 13 ft. 7 in. high, connected with the main flue, and situated between the destructor cells and the boiler. Internally it consists of a spiral flue traversing the entire circumference and winding upwards to the top of the chamber. There is an interior well or chamber 6 ft. diameter by 12 ft. high, having a domed top, and communicating with the outer spiral flue by four ports at the top of the chamber. Dust traps, baffle walls, and cleaning doors are also provided for the retention and subsequent weekly removal of the flue dust. The apparatus forms a large reservoir of heat maintained at a steady temperature of from 1500° to 1800° F., and is useful in keeping up steam in the boiler at an equable pressure for a long period. It requires no attention, and has proved successful for its purpose.

Travelling cranes for transporting refuse and feeding cells are sometimes employed at destructor stations, as, for example, at Hamburg. Here the transportation of the refuse is effected by means of specially constructed water-tight iron waggons, containing detachable boxes provided with two double-flap doors at the top for loading, and one flap-door at the back for unloading. There are thirty-six furnaces of the Horsfall type placed in two ranks, each arranged in three blocks of six in the large furnace hall. An electric crane running above each rank lifts the boxes off the waggons and carries them to the feeding-hole of each cell. Here the box is tipped up by an electric pulley and emptied on to the furnace platform. Where the travelling crane is used, the carts (four-wheeled) bringing the refuse may be constructed so that the body of the carriage can be taken off the wheels, lifted up and tipped direct over the furnace as required, and returned again to its frame. The adoption of the travelling crane admits of the reduction in size of the main building, as less platform space for unloading refuse carts is required; the inclined roadway may also be dispensed with. Where a destructor site will not admit of an inclined roadway and platform, the refuse may be discharged from the collecting carts into a lift, and thence elevated into the feeding-bins.

*Working of destructors.*

The general arrangement of a battery of refuse cells at a destructor station is illustrated by Fig. 5. The cells are arranged either side by side, with a common main flue in the rear, or back to back with the main flue placed in the centre and leading to a tall chimney-shaft. The heated gases on leaving the cells pass through the combustion chamber into the main flue, and thence go forward to the boilers, where their heat is absorbed and utilized. Forced draught is supplied from fans through a conduit commanding the whole of the cells. An inclined roadway of as easy gradient as circumstances will admit, is provided for the conveyance of the refuse to the tipping platform, from which it is fed through feed-holes into the furnaces. In the installation of a destructor, the choice of suitable plant and the general design of the works must be largely dependent upon local requirements, and should be entrusted to an engineer experienced in these matters. The following primary considerations, however, may be enumerated as materially affecting the design of such works:—

(*a*) The plant must be simple, easily worked without stoppages, and without mechanical complications upon which stokers may lay the blame for bad results. (*b*) It must be strong, must withstand variations of temperature, must not be liable to get out of order, and should admit of being readily repaired. (*c*) It must be such as can be easily understood by stokers or firemen of average intelligence, so that the continuous working of the plant may not be disorganized by change of workmen. (*d*) A sufficiently high temperature must be attained in the cells to reduce the refuse to an entirely innocuous clinker, and all fumes or gases should pass either through an adjoining red-hot cell or through a chamber whose temperature is maintained by the ordinary working of the destructor itself at a degree sufficient to exclude the possibility of the escape of any unconsumed gases, vapours, or particles. The temperature may vary between 1500° and 2000°. (*e*) The plant must be so worked that while some of the cells are being recharged, others are at a glowing red heat, in order that a high temperature may be uniformly maintained. (*f*) The design of the furnaces must admit of clinkering and recharging being easily and quickly performed, the furnace doors being open for a minimum of time so as to obviate the inrush of cold air to lower the temperature in main flues, &c. (*g*) The chimney draught must be assisted with forced draught from fans or steam jet to a pressure of $1\frac{1}{2}$ inches to 2 inches under grates by water-gauge. (*h*) Where a destructor is required to work without risk of nuisance to the neighbouring inhabitants, its efficiency as a refuse destructor plant must be primarily kept in view in designing the works, steam-raising being regarded as a secondary consideration. Boilers should not be placed immediately over a furnace so as to present a large cooling surface, whereby the temperature of the gases is reduced before the organic matter has been thoroughly burned. (*i*) Where steam-power and a high fuel efficiency are desired a large percentage of $CO_2$ should be sought in the furnaces with as little excess of air as possible, and the flue gases should be utilized in heating the air-supply to the grates, and the feed-water to the boilers. (*j*) Ample boiler capacity and hot-water storage feed-tanks should be included in the design where steam-power is required.

*Cost.*

As to the initial cost of the erection of refuse destructors, few trustworthy data can be given. The outlay necessarily depends, amongst other things, upon the difficulty of preparing the site, upon the nature of the foundations required, the height of the chimney-shaft, the length of the inclined or approach roadway, and the varying prices of labour and materials in different localities. As an example may be mentioned the case of Bristol, where, in 1892, the total cost of constructing a 16-cell Fryer destructor was £11,418, of which £2909 was expended on foundations, and £1689 on the chimney-shaft; the cost of the destructor proper, buildings, and approach road was therefore £6820, or about £426 per cell. The cost per ton of burning refuse in destructors depends mainly upon—(*a*) The price of labour in the locality, and the number of "shifts" or changes of workmen per day; (*b*) the type of furnace adopted; (*c*) the nature of the material to be consumed; (*d*) the interest on and repayment of capital outlay. The cost of burning, ton for ton consumed, in high-temperature furnaces, including labour and repairs, is not greater than in slow-combustion destructors. The average cost of burning refuse at twenty-four different towns throughout England, exclusive of interest on the cost of the works, is 1s. $1\frac{1}{2}$d. per ton burned; the minimum cost is 6d. per ton at Bradford, and the maximum cost 2s. 10d. per ton at Battersea. At Shoreditch the cost per ton for the year ending 25th March 1899, including labour, supervision, stores, repairs, &c. (but exclusive of interest on cost of works), was 2s. 6·9d. The quantity of refuse burned per cell per day of 24 hours varies from about 4 tons up to 20 tons. The ordinary low-temperature destructor, with 25 square feet grate area, burns about 20 ℔ of refuse per square foot of grate area per hour, or between 5 and 6 tons per cell per 24 hours. The Meldrum destructor furnaces at Rochdale burn as much as 66 ℔ per square foot of grate area per hour, and the Beaman and Deas destructor at Llandudno 71·7 ℔ per square foot per hour. The amount, however, always depends materially on the care observed in stoking, the nature of the material, the frequency of removal of clinker, and on the question whether the whole of the refuse passed into the furnace is thoroughly cremated.

*Residues.*

The amount of residue in the shape of clinker and fine ash varies from 22 to 37 per cent. of the bulk dealt with. From 25 to 30 per cent. is a very usual amount. At Shoreditch, where the refuse consists of about 8 per cent. of straw, paper, shavings, &c., the residue contains about 29 per cent. clinker, 2·7 per cent. fine ash, ·5 per cent. flue dust, and ·6 per cent. old tins, making a total residue of 32·8 per cent. As the residuum amounts to from $\frac{1}{4}$th to $\frac{1}{3}$rd of the total bulk of the refuse dealt with, it is a question of the utmost importance that some profitable, or at least inexpensive, means should be devised for its regular disposal. Among other purposes, it has been used for bottoming for macadamized roads, for the manufacture of concrete, for making paving slabs, for forming suburban footpaths or cinder footwalks, and for the manufacture of mortar. The last is a very general, and in many places profitable, mode of disposal.

Through defects in the design and management of many of the early destructors complaints of nuisance frequently arose, and these have, to some extent, brought destructor installations into disrepute. Although some of the older furnaces were decided offenders in this respect, that is by no means the case with the modern improved type of high-temperature furnace; and often, were it not for the great prominence in the landscape of a tall chimney-shaft, the existence of a refuse destructor in a neighbourhood would not be generally known to the inhabitants. A modern furnace, properly designed and worked, will give rise to no nuisance, and may be safely erected in the midst of a populous neighbourhood. To ensure the perfect cremation of the refuse and of the gases given off, forced draught is essential.

*Forced draught.*

This is supplied either as air draught delivered from a rapidly revolving fan, or as steam blast, as in the Horsfall steam jet or the Meldrum blower. With a forced blast less air is required to obtain complete combustion than by chimney draught. The forced draught grate requires

little more than the quantity theoretically necessary, while with chimney draught more than double the theoretical amount of air must be supplied. With forced draught, too, a much higher temperature is attained, and if it is properly worked, little or no cold air will enter the furnaces during stoking operations. As far as possible a balance of pressure in the cells during clinkering should be maintained just sufficient to prevent an inrush of cold air through the flues. The forced draught pressure should not exceed 2 inches' water-gauge. The efficiency of the combustion in the furnaces is conveniently measured by the "Econometer," which registers continuously and automatically the proportion of $CO_2$ passing away in the waste gases; the higher the percentage of $CO_2$ the more efficient the furnace, provided there is no formation of CO, the presence of which would indicate incomplete combustion. The theoretical maximum of $CO_2$ for refuse burning is about 20 per cent.; and, by maintaining an even clean fire, by admitting secondary air over the fire, and by regulating the dampers or the air-pressure in the ash-pit, an amount approximating to this percentage may be attained in a well-designed furnace if properly worked. If the proportion of free oxygen (*i.e.*, excess of air) is large, more air is passed through the furnace than is required for complete combustion, and the heating of this excess is clearly a waste of heat. The position of the econometer in testing should be as near the furnace as possible, as there may be considerable air leakage through the brickwork of the flues.

***Calorific value.***

The modern high-temperature destructor, to render the refuse and gases perfectly innocuous and harmless, is worked at a temperature varying from 1250° to 2000° F., and the maintenance of such temperatures has very naturally suggested the possibility of utilizing this heat-energy for the production of steam-power. Successful steam-raising destructor stations have been in operation during recent years in England, and experience shows that a considerable amount of energy may be derived therefrom, amply justifying a reasonable increase of expenditure on plant and labour. The actual calorific value of the refuse material necessarily varies, but, as a general average, experience shows that, with suitably-designed and properly-managed plant, an evaporation of 1 ℔ of water per pound of refuse burned is a result which may be readily attained, and affords a basis of calculation which engineers may safely adopt in practice. Many destructor steam-raising plants, however, give considerably higher results, as will be seen from the following table:—

| Town. | Type of Furnaces. | Water evaporated per ℔ of Refuse Actual. | Water evaporated per ℔ of Refuse, from and at 212° Fahr. | Average Steam-pressure per square inch. | Total Indicated Horse-power developed per hour (based on 20 ℔ of steam per I.H.P. per hour). |
|---|---|---|---|---|---|
| Rochdale. | Meldrum Bros. (4 cells) | 1·64 ℔ | 1·97 ℔ | 113 ℔ | 350 |
| Hereford. | Meldrum Bros. (4 cells) | 1·51 ,, | 1·82 ,, | 70·92 ,, | 236 |
| Darwen. | Meldrum Bros. (4 cells) | 1·48 ,, | 1·55 ,, | 183 ,, | 275 |
| Oldham. | Horsfall (10 cells) | 1·11 ,, | 1·33 ,, | 128 ,, | 200 |
| Canterbury | Beaman & Deas (2 cells) | 1·41 ,, | 1·59 ,, | 132 ,, | 236 |

From actual experience it may be accepted, therefore, that the calorific value of unscreened house refuse varies from 1 to 2 ℔ of water evaporated per pound of refuse burned, the exact proportion depending upon the quality and condition of the material dealt with. Taking the evaporative power of coal at 10 ℔ of water per pound of coal, this gives for domestic house refuse a value of from $\frac{1}{10}$ to $\frac{1}{5}$ that of coal; or, with coal at 20s. per ton, refuse has a commercial value of from 2s. to 4s. per ton. In London the quantity of house refuse amounts to about $1\frac{1}{4}$ million tons per annum, which is equivalent to from 4 cwt. to 5 cwt. per head per annum. If it be burned in furnaces giving an evaporation of 1 ℔ of water per pound of refuse, it would yield a total power annually of about 138 million brake horse-power hours, and equivalent cost of coal at 20s. per ton for this amount of power, even when calculated upon the very low estimate of 2 ℔[1] of coal per brake horse-power hour, works out at over £123,000. On the same basis, the refuse of a medium-sized town, with, say, a population of 70,000 yielding refuse at the rate of 5 cwt. per head per annum, would afford 112 indicated horse-power per ton burned, and the total indicated horse-power hours per annum would be

$$\frac{70{,}000 \times 5 \text{ cwt.}}{20} \times 112 = 1{,}960{,}000 \text{ I.H.P. hours annually.}$$

If this were applied to the production of electric energy, the electrical horse-power hours would be (with a dynamo efficiency of 90 per cent.)

$$\frac{1{,}960{,}000 \times 90}{100} = 1{,}764{,}000 \text{ E.H.P. hours per annum;}$$

and the watt-hours per annum at the central station would be

$$1{,}764{,}000 \times 746 = 1{,}315{,}944{,}000.$$

Allowing for a loss of 10 per cent. in distribution, this would give 1,184,349,600 watt-hours available in lamps, or with 8 candle-power lamps taking 30 watts of current per lamp, we should have

$$\frac{1{,}184{,}349{,}600 \text{ watt-hours}}{30 \text{ watts}} = 39{,}478{,}320 \text{ 8-c.p. lamp-hours per annum;}$$

that is, $\frac{39{,}478{,}320}{70{,}000 \text{ population}} = 563$ 8-c.p. lamp-hours per annum per head of population.

Taking the loss due to the storage which would be necessary at 20 per cent. on three-quarters of the total or 15 per cent. upon the whole, there would be 478 8-c.p. lamp-hours per annum per head of the population; *i.e.*, if the power developed from the refuse were fully utilized, it would supply electric light at the rate of one 8-c.p. lamp per head of the population for about $1\frac{1}{3}$ hours for every night of the year.

***Difficulties.***

In actual practice, when the electric energy is for the purposes of lighting only, difficulty has been experienced in fully utilizing the thermal energy from a destructor plant owing to the want of adequate means of storage either of the thermal or of the electric energy. A destructor station usually yields a fairly definite amount of thermal energy uniformly throughout the twenty-four hours, while the consumption of electric-lighting current is extremely irregular, the maximum demand being about four times the mean demand. The period during which the demand exceeds the mean is comparatively short, and does not exceed about six hours out of the twenty-four, while for a portion of the time the demand may not exceed $\frac{1}{20}$th of the maximum. This difficulty, at first regarded as somewhat grave, is now substantially minimized by the provision of ample boiler capacity, or by the introduction of feed thermal storage vessels in which hot feed-water may be stored during the hours of light load (say eighteen out of the twenty-four), so that at the time of maximum load the boilers may be filled directly from these vessels, which work at the same pressure and temperature as the boiler. Further, the difficulty above mentioned will disappear entirely at stations where there is a fair day load which practically ceases at about the hour when the illuminating load comes on, thus equalizing the demand upon both destructor and electric plant throughout the twenty-four hours. This arises in cases where current is consumed during the day for motors, fans, lifts, electric tramways, and other like purposes, and, as the employment of electric energy for these services is rapidly becoming general, no difficulty need be anticipated in the successful working of combined destructor and electric plants where these conditions prevail. The more uniform the electrical demand becomes, the more fully may the power from a destructor station be utilized. In the case above cited of a town of 70,000 population, the horse-power to be derived from the refuse, calculated upon the basis of 2 ℔ of coal per brake horse-power hour, which is the utmost efficiency practicable even for very good steam-engines, will cost £1750 per annum for fuel with coal at 20s. per ton, and, in practice, the actual cost would doubtless be nearly double. At Shoreditch during the year ending March 1899, a total of 1,031,348 Board of Trade units of electric energy was supplied to consumers; of this about seven-tenths were generated from the refuse of the district, and on many occasions a load of 400 kilowatts (*i.e.*, $\frac{400 \text{ kilo.} \times 1000}{746} \times \frac{100}{90} = 596$ horse-power) has been carried by refuse fuel only. Some 200 municipalities in England have laid down destructor plants, but although the great majority are utilizing some of the surplus heat generated by the furnaces, at comparatively few stations is the full thermal energy of the refuse turned to commercial utility owing to the fact that the plants were installed before the value of refuse for steam-raising was properly understood. During recent years, however, new and improved plant has been introduced, and in the laying down of all new installations this phase of the question has been kept most prominently in view.

For further information on the subject, reference should be made to William H. Maxwell, Assoc.M.Inst.C.E., on the *Removal and Disposal of Town Refuse, with an exhaustive treat-*

[1] With medium-sized steam plant, a consumption of 4 ℔ of coal per brake horse-power per hour is a very usual performance.

the centre of the town; whilst at the entrance to the large park on the south is the New Palace (1708–18), enlarged in 1850, used as the dower-house. Detmold possesses a natural history museum, theatre, high school, library, the house in which the poet Freiligrath (1810–76) was born, and that in which the dramatist Grabbe (1801–36), also a native, died. Population (1885), 8916; (1900), 11,971.

**Detroit,** a city of the United States, the county seat of Wayne county, and metropolis of the state of Michigan, is situated on the Detroit river in lat. 42° 20′ N. and long. 83° 3′ W. It is generally level, and has an extent along the river of 7 miles and a depth of 3 miles, except that at the centre of the city it extends towards the north more than 5 miles. Its area is 29½ square miles. The streets are very wide, and are kept scrupulously clean. There are three lines of electric street railways, aggregating 160 miles of track, and ten lines of suburban electric cars, carrying both passengers and freight. Sixteen lines of railways connect the city with all parts of the United States and Canada. Ferries connect the city with Windsor and Walkerville in Canada, directly opposite, and with the island park and the various summer resorts along the river front. The foot of each street reaching to the river is converted into a public wharf. There are 28 parks and parkways, aggregating 912 acres, besides the Grand Boulevard, which is a drive 11 miles long, around the city. The largest park is Belle Isle, an island within the city limits, at its eastern extremity, and connected with the mainland by a bridge over the American channel of the Detroit river.

The population in 1890 was 205,876, and in 1900 it had increased to 285,704, of whom 96,503 were foreign-born and 4111 negroes. Out of 78,855 males 21 years of age and over, 3587 (of whom 3262 were foreign-born) were illiterate (unable to write). The birth-rate per thousand averages 14. The death-rate in 1900 was 17·1; in 1890 it was 18·7. There are 69 public schools (3 of which are high schools) and 59 private and parochial schools, employing 1187 teachers. In 1900 there were 91,777 persons of school age (5 to 20 years inclusive). There is one literary college (Jesuit), three colleges of medicine, one of dentistry, and one of law. The State University at Ann Arbor is within easy reach (37 miles). There are four public libraries, the largest of which contains 157,934 volumes. Branches of this library are established in the public schools. The Museum of Art is supported in part by taxation. The building cost $127,000, and the contents, paintings, and articles of vertu are valued at $150,000. There are 80 newspapers and periodicals published in the city, of which 7 are dailies. There are 30 asylums, hospitals, and charitable homes. There are 183 churches, of which 30 are Roman Catholic, 28 Methodist, 25 Lutheran, 24 Episcopal, 17 Baptist.

The basis of the government is the city charter, granted by the State Legislature. The mayor is elected every two years by popular vote; and the council is composed of two members from each of the 17 wards of the city, one from each being elected every year. The waterworks are owned by the city, and are maintained by water rates and an annual tax of $75,000. The supply is taken from Lake St Clair, immediately above the city. The public lighting is entirely electric, and the plant is owned by the city. Much of the lighting is by arc lights on towers 100 to 150 feet high.

Detroit river is so deep at the foot of the streets that any vessel can approach the wharf. It is never so affected by storms that vessels are in danger, and the most severe rains never perceptibly raise its waters. The main commerce of the Great Lakes passes through it. How much this amounts to it is impossible to ascertain, but certainly twice as much as passes the famous Sault Ste Marie Canal, 25,255,810 tons. The shipments of grain from Detroit for 1899 were as follow:—Wheat 1,567,132 bushels, corn 2,304,105 bushels, oats 266,133 bushels, rye 261,869 bushels, and flour 137,000 barrels. There are 23 banks, with an aggregate capital of $7,850,000, deposits amounting to $67,744,955, and total resources of $91,020,715. The bank clearances for the year 1899 were $415,073,499. The assessed valuation of the city, on a basis estimated at 70 per cent. of full value, is $237,799,250, and the entire tax-levy for general purposes about 2 per cent. The total public debt, exclusive of water bonds, is $3,617,165. There is also a debt of the county, for the new county building, of about $1,500,000. The property belonging to the city is valued at $20,430,985. (C. M. B.)

**Deus, João de** (1830–1896), the greatest Portuguese poet of his generation, and perhaps of the 19th century, was born at San Bartholomeu de Messines in the province of Algarbe on 8th March 1830. Matriculating in the faculty of law at the university of Coimbra, he did not proceed to his degree but settled in the city, dedicating himself wholly to the composition of verses, which circulated among professors and undergraduates in manuscript copies. In the volume of his art, as in the conduct of life, he practised a rigorous self-control. Though it is by no means uncommon for Portuguese poets to publish books of verse before they are of age, and though João de Deus was the idol of an academic circle from a very early date, he printed nothing previous to 1855, and the first of his poems to appear in a separate form was *La Lata*, which was issued in 1860. In 1862 he left Coimbra for Beja, where he was appointed editor of *O Bejense*, the chief newspaper in the province of Alemtejo, and four years later he edited the *Folha do Sul*. As the pungent satirical verses entitled *Eleições* prove, he was not an ardent politician, and, though he was returned as Liberal deputy for the constituency of Silves in 1869, he acted independently of all political parties and promptly resigned his mandate. The renunciation implied in the act, which cut him off from all advancement, is in accord with nearly all that is known of his lofty character. In the year of his election as deputy, his friend, José Antonio Garcia Blanco, collected from local journals the series of poems, *Flores do Campo*, which is supplemented by the *Ramo de Flores* (1869). This is João de Deus's masterpiece. *Pires de Marmalada* (1869) is an improvisation of no great merit. The four theatrical pieces—*Amemos o nosso proximo*, *Ser apresentado*, *Ensaio de Casamento*, and *A Viúva inconsolavel*—are prose translations from Méry, cleverly done but not worth the doing. *Horacio e Lydia* (1872), a translation from Ponsard, is a good example of artifice in manipulating that dangerously monotonous measure, the Portuguese couplet. As an indication of a strong spiritual reaction three prose fragments (1873)—*Anna*, *Mãe de Maria*, *A Virgem Maria* and *A Mulher do Levita de Ephrain*—translated from Darboy's *Femmes de la Bible*, are full of significance. The *Folhas soltas* (1876) is a collection of verse in the manner of *Flores do Campo*, brilliantly effective and exquisitely refined. Within the next few years the writer turned his attention to educational problems, and in his *Cartilha maternal* (1876) first expressed the conclusions to which his study of Pestalozzi and Fröbel had led him. This patriotic, pedagogical apostolate was a misfortune for Portuguese literature; his educational mission absorbed João de Deus completely, and is responsible for numerous controversial letters, for a translation

of Théodore-Henri Barrau's treatise, *Des devoirs des enfants envers leurs parents*, for a prosodic dictionary, and for many other publications of no literary value. A copy of verses in Antonio Vieira's *Grinalda de Maria* (1877), the *Loas á Virgem* (1878), and the *Proverbios de Salomão*, are evidence of a complete return to orthodoxy during the poet's last years. By a lamentable error of judgment some worthless pornographic verses entitled *Cryptinas* have been inserted in the completest edition of João de Deus's poems—*Campo de Flores* (Lisbon, 1893). He died at Lisbon on 11th January 1896, was accorded a public funeral, and was buried next to the traditional grave of Camoens in the Jeromite church. His scattered minor prose writings and correspondence have been posthumously published by Dr Theophilo Braga (Lisbon, 1898). His last resting-place corresponds to his position in the history of Portuguese literature. Next to Camoens, no Portuguese poet has been more widely read, more profoundly admired than João de Deus; yet no poet in any country has been more indifferent to public opinion and more deliberately careless of personal fame. He is not responsible for any single edition of his poems, which were put together by pious but ill-informed enthusiasts, who ascribed to him verses that he had not written; he kept no copies of his compositions, seldom troubled to write them himself, and was content for the most part to dictate them to others. He has no great intellectual force, no philosophic doctrine, is limited in theme as in outlook, is curiously uncertain in his touch, often marring a fine poem with a slovenly rhyme or with a misplaced accent; and, on the only occasion when he was induced to revise a set of proofs, his alterations were nearly all for the worse. And yet, though he never appealed to the patriotic spirit, though he wrote nothing at all comparable in force or majesty to the restrained splendour of *Os Lusiadas*, the popular instinct which links his name with that of his great predecessor is eminently just. For Camoens was his model; not the Camoens of the epic, but the Camoens of the lyrics and the sonnets, where the passion of tenderness finds its supreme utterance. Braga has noted five stages of development in João de Deus's artistic life—the imitative, the idyllic, the lyric, the pessimistic, and the devout phases. Under each of these divisions is included much that is of extreme interest, especially to contemporaries who have passed through the same succession of emotional experience, and it is highly probable that *Catúrras* and *Gaspar*, pieces as witty as anything in Bocage but free from Bocage's coarse impiety, will always interest literary students. But it is as the singer of love that João de Deus will delight posterity as he delighted his own generation. The elegiac music of *Rachel* and of *Marina*, the melancholy of *Adeus* and of *Remoinho*, the tenderness and sincerity of *Meu casto lirio*, of *Lagrima celeste*, of *Descalça*, and a score more songs are distinguished by the large, vital simplicity which withstands time. It is precisely in the quality of unstudied simplicity that João de Deus is incomparably strong. The temptations to a display of virtuosity are almost irresistible for a Portuguese poet; he has the tradition of virtuosity in his blood, he has before him the example of all contemporaries, and he has at hand an instrument of wonderful sonority and compass. Yet not once is João de Deus clamorous or rhetorical, not once does he indulge in idle ornament. His prevailing note is that of exquisite sweetness and of reverent purity; yet with all his caressing softness he is never sentimental, and, though he has not the strength for a long flight, emotion has seldom been set to more delicate music. Had he included among his other gifts the gift of selection, had he continued the poetic discipline of his youth instead of dedicating his powers to a task which, well as he performed it, might have been done no less well by a much lesser man, there is scarcely any height to which he might not have risen. (J. F. – K.)

**Deutsch-Brod** (Czech, *Německý Brod*), the chief town of a government district of the same name in Eastern Bohemia, on the Sazawa river, north-west of the Iglau German enclave. It was the scene of a victory by Ziska in 1422 over the Emperor Sigismund, when it was destroyed by the Hussites, and in the preceding century had been a flourishing mining town. It was found impossible, however, to restore the old mines. Deutsch-Brod is now a manufacturing town, producing starch, cloth, glass, spodium, flour, beer, and it has a number of saw-mills. Population, almost exclusively Czech (1890), 5735; (1900), 6526.

**Deutz,** a town of Prussia, incorporated with COLOGNE (*q.v.*) in 1888.

**Déva,** a corporate town of South-East Hungary, near the river Maros, 82 miles east by north of Temesvár; capital of the county of Hunyad. It existed in the time of the Romans, but its oldest edifice is the Calvinist church, dating from the epoch of the Hunyadis (15th century). The neighbourhood was the scene of important events in the War of Independence, 1848–49, and the ruins of the fortress, which was then destroyed, are still very imposing. Population (1891), 4657; (1900), 7089.

**Deventer,** an old Hanse town in the province of Overyssel, Netherlands, on the river Yssel, 25 miles north of Arnheim. The rise of Amsterdam and the shallowing of the Yssel contributed to its decline, but it remains a commercial centre of some importance, trading with the eastern parts of Guelderland and Overyssel. Connexion with Borculo by steam tram has been established; also an institution to carry out agricultural experiments. A new theatre was built in 1875. Population (1900), 26,212.

**De Vere, Aubrey Thomas** (1814–1902), Irish poet and critic, was born at Curragh Chase, county Limerick, on 10th January 1814, being the third son of Sir Aubrey de Vere Hunt. In 1832 his father dropped the final name by royal license. Aubrey de Vere was educated at Trinity College, Dublin, and in his twenty-eighth year began his literary career with *The Waldenses*, which he followed up in the next year by *The Search after Proserpine*. Thenceforward he was continually engaged, till his death on 20th January 1902, in the production of poetry and criticism, devoting a long and industrious life to his enthusiasm for literature. His best known works are: in verse, *The Sisters*, 1861; *The Infant Bridal*, 1864; *Irish Odes*, 1869; *Legends of St Patrick*, 1872; and *Legends of the Saxon Saints*, 1879; and in prose, *Essays chiefly on Poetry*, 1887; and *Essays chiefly Literary and Ethical*, 1889. He also wrote a picturesque volume of travel-sketches, and two dramas in verse, *Alexander the Great*, 1874; and *St Thomas of Canterbury*, 1876; both of which, though they contain fine passages, suffer from diffuseness and a lack of dramatic spirit. The characteristics of Aubrey de Vere's poetry are "high seriousness" and a fine religious enthusiasm. His research in questions of faith led him to the Roman Church; and in many of his poems, notably in the volume of sonnets called *St Peter's Chains*, 1888, he made rich additions to devotional verse. He was a disciple of Wordsworth, whose calm meditative serenity he often echoed with great felicity; and his affection for Greek poetry, truly felt and understood, gave dignity and weight to his own versions of mythological idylls. But perhaps he will be chiefly remembered for the impulse which he gave to the study of Celtic legend and literature. In this direction he has had many followers, who have sometimes assumed the appearance of pioneers; but after Matthew

Arnold's fine lecture on "Celtic Literature," nothing perhaps has had more influence upon the return to Celtic interests than Aubrey de Vere's tender insight into the Irish character, and his stirring reproductions of the early Irish epic poetry. (A. WA.)

**Devizes,** a municipal borough and market town in the Devizes parliamentary division (since 1885) of Wiltshire, England, 23 miles north-north-west of Salisbury by rail. A cottage hospital has been erected. The scanty remains of the ancient castle are mostly incorporated in a modern residence. There are large engineering works and manufactures of agricultural implements; also a large tobacco and snuff factory. Area, 907 acres; population (1881), 6649; (1901), 6532. The Devizes Union District, excluding the borough of Devizes, had a population of (1891) 13,318; (1901), 13,070.

**Devonport,** a municipal (extended 1898), county (1888), and parliamentary borough, naval arsenal, royal dockyard, and garrison town of England, on the Hamoaze or estuary of the Tamar, 1 mile west-north-west of Plymouth, 248 miles by rail west-south-west of London. The borough is divided into 15 wards under a council of 60 members. Among recent institutions are a free library (1882); the Naval Engineering College (1880), enlarged in 1896 by the addition of a new wing costing £30,000, the only establishment of the kind in the United Kingdom (Portsmouth College having been abolished), with 200 students resident in the college; the municipal technical schools, opened in 1899, 80 per cent. of the students being connected with the dockyard; and the new naval barracks (1885). There is a public park (35 acres). No. 3 dock of Devonport dockyard (72 acres) has been recently enlarged to accommodate the biggest ships, and the adjoining dock southwards now admits all but the largest cruisers. One of the building slips, still roofed, measures over 6000 square yards. In a "shed," converted into an open slip, was built the "Ocean," launched in 1898—Devonport's first battle-ship. A new slip suitable for battle-ships or cruisers of the largest type was begun in 1900. Over 7000 workmen are employed in the dockyard. A ropery, producing half the hempen ropes used in the navy, employs 100 women. Keyham steamyard (72 acres), to the north of Devonport, opened in 1853, comprises 3 large docks and 2 basins, the Queen's Dock being 418 feet long. To the north of the docks, the factory, quadrangular in shape, includes an engineer students' shop, a torpedo shop, machinery shops, engine smithery, erecting shop and turnery, iron and brass foundries, pattern and millwrights' shops, flanging works, &c. The Keyham extension works, begun in 1896, includes the reclamation of nearly 100 acres of land to the north of Keyham and of the Naval Engineering College. The scheme provides a closed basin 1550 feet long, 1000 feet wide, and 55 feet deep, communicating with the Hamoaze by a spacious lock as well as a caisson entrance; another tidal basin (10 acres); and 3 graving docks. On the completion, some six or seven years hence, of the extension, the port will command 5 basins and 10 docks, and rank as by far the most capacious arsenal of the world, disposing of a continuous sea frontage, extending nearly three miles, of docks and arsenal. Area of municipal and county borough before extension, 1760 acres; population (1881), 48,939; (1891), 54,803. The extended area is 3160 acres; population (1891), 55,981; (1901), 69,674.

**Devonshire,** a south-western maritime county of England, bounded N.W. by the Bristol Channel, N.E. and E. by Somerset and Dorset, S. by the English Channel, and W. by Cornwall.

*Area and Population.*—The area of the ancient county, as given in the census returns, is 1,667,097 acres, or 2605 square miles. The population in 1881 was 603,654, and in 1891 was 631,808, of whom 297,898 were males and 333,910 females, the number of persons per square mile being 243, and of acres to a person 2·64. In 1901 the population was 660,444. The area of the administrative county, exclusive of the county boroughs, was 1,661,914 acres, with a population of 455,353, and including the county boroughs its area was identical with that of the ancient county, but since 1891 certain changes have been made. In 1896 the parishes of Chardstock and Hawkchurch were transferred from Dorset to Devon; in the same year the boundaries of the county borough of Plymouth were extended; and in 1898 the county borough of Plymouth was again extended. The area of the registration county is 1,650,705 acres, with a population in 1891 of 636,225, of which 336,936 were urban and 299,289 rural. Within this area the increase of population between 1881 and 1891 was 4·60 per cent. The excess of births over deaths between 1881 and 1891 was 63,001, and the increase of resident population was 27,969.

The following table gives the number of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898:—

| Year. | Marriages. | Births. | Deaths. | Illegitimate Births. | |
|---|---|---|---|---|---|
| | | | | Males. | Females. |
| 1880 | 4521 | 18,218 | 12,167 | 436 | 380 |
| 1890 | 4851 | 16,893 | 11,903 | 351 | 388 |
| 1898 | 5038 | 16,222 | 10,844 | 350 | 305 |

The number of marriages in 1899 was 5245, of births 16,294, and of deaths 11,562.

The following table shows the marriage, birth, and death rates per 1000 of the population, with the percentage of illegitimate births, for a series of years:—

| | 1870–79. | 1880. | 1880–89. | 1890. | 1888–97. | 1898. |
|---|---|---|---|---|---|---|
| Marriage-rate . | 15·3 | 14·8 | 14·9 | 15·3 | 15·1 | 15·4 |
| Birth-rate . | 29·9 | 29·8 | 28·8 | 26·6 | 26·4 | 24·8 |
| Death-rate . | 19·8 | 19·9 | 18·4 | 18·8 | 17·5 | 15·7 |
| Percentage of illegitimate births | 5·2 | 4·5 | 4·6 | 4·4 | 4·2 | 4·0 |

The number of Scots in the county in 1891 was 3316, of Irish 6537, and of foreigners 1789.

*Constitution and Government.*—The ancient county is divided into eight parliamentary divisions, and it also includes the parliamentary boroughs of Devonport and Plymouth returning two members, and the borough of Exeter returning one. The administrative county includes thirteen municipal boroughs: Barnstaple (14,137), Bideford (8754), Dartmouth (6579), Devonport (69,674), Exeter (46,940), Honiton (3271), Okehampton (2568), Plymouth (107,509), South Molton (2848), Tiverton (10,382), Torquay (33,625), Great Torrington (3241), and Totnes (4034). Of these, Devonport, Exeter, and Plymouth are county boroughs. The following are urban districts: Ashburton (2628), Bampton (1657), Brixham (8090), Buckfastleigh (2520), Budleigh Salterton (1883), Crediton (3974), Dawlish (4003), East Stonehouse (15,111), Exmouth (10,487), Heavitree (7529), Ilfracombe (8557), Ivybridge (1575), Kingsbridge (3025), Lynton (1641), Newton Abbot (12,518), Northam (5357), Ottery St Mary (3495), Paignton (8385), St Mary Church (6849), St Thomas the Apostle (8245), Salcombe (1710), Seaton (1325), Sidmouth (4201), Tavistock (4728), and Teignmouth (8636). Devonshire is in the western circuit, and assizes are held at Exeter. The boroughs of Barnstaple, Bideford, Dartmouth, Devonport, Exeter, Plymouth, South Molton, and Tiverton have separate courts of quarter sessions. The ancient county, which is almost entirely in the diocese of Exeter, contains 506 entire ecclesiastical parishes, and parts of five others.

*Education.*—There is a residential training college (diocesan) for schoolmasters at Exeter. At Exeter are also the West of England Institution for the deaf and the West of England Institution for the blind, while at Plymouth are the South Devon and Cornwall Institution for the blind and a school board deaf school. The number of elementary schools on 31st August 1899 was 643, of which 239 were board and 404 voluntary schools, the latter including 349 National Church of England schools, 6 Wesleyan, 13 Roman Catholic, and 36 "British and other." The average attendance at board schools was 43,261, and at voluntary schools 50,162. The total school board receipts for the year ended 29th September 1898 were over £144,335. The income under the Technical Instruction Act was over £602, and that under the Agricultural Rates Act over £6114.

*Agriculture.*—About three-fourths of the total area of the county is under cultivation, and of this more than a half is in permanent pasture, a large number of cattle and sheep being raised. The Devon breed of cattle are well adapted both for fattening and dairy purposes. For sheep there are, in addition to the permanent

pasture of the cultivated area, about 158,000 acres in hill pasturage. Over 86,000 acres are under woods and about 27,000 acres under orchards, chiefly of apple trees, nearly every farm having a large orchard for the manufacture of cider. Of the acreage under corn crops, more than one-half is under oats, and less than a third under wheat, the acreage of which has diminished since 1880 about a third. The bulk of the acreage under green crops is occupied by turnips, mangold, and cabbage, potatoes occupying only about a tenth of the whole acreage. The following table gives the larger main divisions of the cultivated area at intervals of five years from 1880 :—

| Year. | Total Area under Cultivation. | Corn Crops. | Green Crops. | Clover. | Permanent Pasture. | Fallow. |
|---|---|---|---|---|---|---|
| 1880 | 1,150,888 | 278,413 | 138,735 | 190,197 | 509,694 | 33,833 |
| 1885 | 1,193,108 | 252,244 | 140,822 | 196,743 | 582,203 | 21,063 |
| 1890 | 1,208,467 | 242,864 | 132,485 | 201,326 | 615,230 | 15,532 |
| 1895 | 1,213,913 | 222,896 | 127,905 | 218,965 | 633,055 | 9,596 |
| 1900 | 1,210,034 | 225,203 | 122,769 | 219,091 | 634,427 | 7,179 |

The following table gives particulars regarding the principal live-stock for the same years :—

| Year. | Total Horses. | Total Cattle. | Cows or Heifers in Milk or in Calf. | Sheep. | Pigs. |
|---|---|---|---|---|---|
| 1880 | 53,944 | 229,471 | 80,280 | 773,916 | 84,815 |
| 1885 | 54,579 | 253,421 | 90,937 | 874,606 | 99,513 |
| 1890 | 55,280 | 259,876 | 95,960 | 913,562 | 123,227 |
| 1895 | 59,916 | 263,506 | 94,685 | 874,408 | 123,937 |
| 1900 | 54,526 | 279,728 | 91,872 | 846,324 | 95,944 |

*Industries and Trade.*—According to the annual report for 1898 of the chief inspector of factories (issued 1900), the total number of persons employed in factories and workshops in 1897 was 36,887, as compared with 34,608 in 1896. Textile factories employed only 2356, of whom 1197 were employed in the manufacture of woollen goods, lace employing 879. Honiton lace is made in other parts of the county as well as in Honiton. In non-textile factories 24,002 persons were employed, there being an increase between 1895 and 1896 of 10·4 per cent., and between 1896 and 1897 of 7·6 per cent. In the manufacture of machines, appliances, conveyances, and tools, 8534 persons were employed, chiefly in the Government establishments at Devonport and Keyham; in the clothing industry 2800, there being a considerable trade in costumes and outfitting; in the manufacture of paper 2755; in the clay and stone industry (including articles in pottery and terra-cotta at Bovey Tracy, Watcombe, &c.), 1047. Of the 10,529 persons employed in workshops as many as 6342 were employed in the clothing industry, and 1576 in the manufacture of machines, appliances, conveyances, and tools. For mineral purposes Devon is included in the duchy of Cornwall. The total number of persons employed in mining in 1899 was 3085. Increasing quantities of marble, granite, and other building stones, as well as limestone and roofing slates, are being dug. In 1899 as many as 527,026 tons of limestone were raised, 290,991 tons of clay (value £82,244), 48,651 tons of granite, 71,487 tons of sandstone, and 13,901 tons of slate. Manganese and tin are mined in only very small quantities. The following table gives particulars regarding the production of arsenic, china clay, and copper in 1890 and 1898 :—

| Year. | Arsenic. | | China Clay. | | Copper. | |
|---|---|---|---|---|---|---|
| | Tons. | Value. | Tons. | Value. | Tons. | Value. |
| 1890 | 4133 | £34,224 | 60,346 | £30,173 | 6038 | £9197 |
| 1899 | 2468 | £40,941 | 52,198 | £30,187 | 990 | £2292 |

Much of the fishing is carried on within the 3 mile limit. Pilchard, cod, sprats, brill, plaice, soles, turbot, shrimps, lobster, oyster, and mussels, are met with, besides herrings and mackerel, which are rather plentiful. The principal fishing stations are Brixham and Plymouth, but there are small ones in all the bays and river outlets. The total amount of fish landed at Brixham in 1899 was 62,337 cwt., valued at £70,685; and at Plymouth 138,972 cwt., valued at £89,003. The annual average for all stations is about 280,000 cwt., valued at £180,000. Much of the fish landed at Plymouth is from Cornwall.

**Devonshire, Spencer Compton Cavendish,** 8th Duke of (1833– —), was born on 23rd July 1833. He was the son of the seventh duke of Devonshire (who died in 1891 at the age of 83), a man who, without playing a prominent part in public affairs, exercised great influence not only by his position but also by his abilities. In 1854 the marquis of Hartington, as he then was, took his degree at Trinity College, Cambridge, and in 1857 was returned to Parliament for North Lancashire. At the opening of the new Parliament of 1859 he moved the amendment to the address which overthrew the Government of Lord Derby. In 1863 he was Under Secretary for War, and on the formation of the Russell–Gladstone administration at the death of Lord Palmerston he entered it as War Secretary. He retired with his colleagues in July 1866; but upon Mr Gladstone's return to power in 1868 he became Postmaster-General, which office he exchanged in 1871 for that of Secretary for Ireland. When Mr Gladstone, after his electoral defeat and consequent resignation in 1874, temporarily withdrew from the leadership of his party in January 1875, Lord Hartington was chosen his successor. Mr W. E. Forster, who had taken a much more prominent part in public life, was the only other possible nominee, but he declined to stand. Lord Hartington's rank no doubt told in his favour, and Mr Forster's Education Bill had offended the Nonconformist members, who would probably have withheld their support. Lord Hartington's prudent management in difficult circumstances laid his followers under great obligations, since not only was the opposite party in the ascendant, but his own former chief was indulging in the freedom of independence. After the complete defeat of the Conservatives in the general election of 1880, a large proportion of the party would have rejoiced if Lord Hartington could have taken the Premiership instead of Mr Gladstone, and the Queen, in strict conformity with constitutional usage, sent for him as leader of the Opposition. Mr Gladstone, however, was clearly master of the situation: no Cabinet could be formed without him, nor could he reasonably be expected to accept a subordinate post. Lord Hartington, therefore, gracefully abdicated the leadership which he had temporarily assumed, and became Secretary of State for India, from which office, in December 1882, he passed to the War Office. His administration was memorable for the expeditions of General Gordon and Lord Wolseley to Khartum. In June 1885 he resigned along with his colleagues, and in December was elected for the Rossendale Division of Lancashire, created by the new Reform Bill. Immediately afterwards the great political opportunity of Lord Hartington's life came to him in Mr Gladstone's conversion to Home Rule. Lord Hartington's refusal to follow his leader in this course inevitably made him the chief of the new Liberal Unionist party, composed of a large and influential section of the old Liberals. In this capacity he moved the first resolution at the famous public meeting at the Opera House, and also, in the House of Commons, moved the rejection of Mr Gladstone's Bill on the second reading. During the memorable electoral contest which followed, no election excited more interest than Lord Hartington's for the Rossendale Division, where he was returned by a majority of nearly 1500 votes. In the new Parliament he held a position much resembling that which Sir Robert Peel had occupied after his fall from power, the leader of a small, compact party, the standing and ability of whose members were out of all proportion to their numbers, generally esteemed and trusted beyond any other man in the country, yet in his own opinion forbidden to think of office. Lord Salisbury's overtures, at all events, were declined, and Lord Hartington con-

tinued to discharge the delicate duties of the leader of a middle party with no less judgment than he had shown when leading the Liberals during the interregnum of 1875–80. It was not until 1895, when the differences between Conservatives and Liberal Unionists had become almost obliterated by changed circumstances and the habit of acting together, that the duke of Devonshire, as he had become by the death of his father in 1891, consented to enter Lord Salisbury's third Ministry as President of the Council. The duke thus was the nominal representative of education in the Cabinet at a time when educational questions were rapidly becoming of great importance; and the duke's own technical knowledge of this difficult and intricate question being admittedly superficial, a good deal of criticism from time to time resulted. His great contribution to public life, however, has been the weight of character which procured for him universal respect and confidence, and exempted him from bitter attack, even from his most determined political opponents. No man ever doubted the duke of Devonshire's patriotism, or felt entirely secure in differing from his judgment. Wealth and rank combined with character to place him in a measure above party: and he remained a luminous example of the benefit which a democratic community may derive from the existence within it of an aristocratic class and the participation of its members in public affairs. The duke succeeded his father as Chancellor of the University of Cambridge in 1892, and is a Knight of the Garter.

**Dewar, James** (1842– ——), British chemist and physicist, was born at Kincardine-on-Forth, Scotland, on 20th September 1842. He was educated at Dollar Academy and Edinburgh University, being at the latter first a pupil, and afterwards the assistant, of the late Lord Playfair, then professor of chemistry; he also studied under Kekulé at Ghent. In 1875 he was elected Jacksonian professor of natural experimental philosophy at Cambridge, becoming a fellow of Peterhouse, and in 1877 he succeeded Dr J. H. Gladstone as Fullerian professor of chemistry in the Royal Institution, London. He has been president of the Chemical Society and of the Society of Chemical Industry, served on the Balfour Commission on London Water Supply (1893–94), and as a member of the Committee on Explosives (1888–91) invented cordite jointly with Sir Frederick Abel. His scientific work covers a wide field. Of his earlier papers, some deal with questions of organic chemistry, others with Graham's hydrogenium and its physical constants, others with high temperatures, *e.g.*, the temperature of the sun and of the electric spark, others again with electro-photometry and the chemistry of the electric arc. With Professor M'Kendrick, of Glasgow, he investigated the physiological action of light, and examined the changes which take place in the electrical condition of the retina under its influence. With Professor G. D. Liveing, one of his colleagues at Cambridge, he began in 1878 a long series of spectroscopic observations, the most recent of which have been devoted to the spectroscopic examination of various gaseous constituents separated from atmospheric air by the aid of low temperatures. Since the time that liquid air and liquid oxygen have been available in considerable quantities, he has been joined by Professor J. A. Fleming, of University College, London, in the investigation of the electrical behaviour of substances cooled to very low temperatures. His name is most widely known in connexion with his work on the liquefaction of the so-called permanent gases and his researches at temperatures approaching the zero of absolute temperature. His interest in this branch of inquiry dates back at least as far as 1874, when he discussed the "Latent Heat of Liquid Gases" before the British Association. In 1878 he devoted a Friday evening lecture at the Royal Institution to the then recent work of Cailletet and Pictet, and exhibited for the first time in Great Britain the working of the Cailletet apparatus. Six years later, in the same place, he described the researches of Wroblewski and Olszewski, and illustrated for the first time in public the liquefaction of oxygen and air, by means of apparatus specially designed for optical projection so that the actions taking place might be visible to the audience. Soon afterwards he constructed a machine from which the liquefied gas could be drawn off through a valve for use as a cooling agent, and he showed its employment for this purpose in connexion with some researches on meteorites; about the same time he also obtained oxygen in the solid state. By 1891 he had designed and erected at the Royal Institution an apparatus which yielded liquid oxygen by the pint, and towards the end of that year he showed that both liquid oxygen and liquid ozone are strongly attracted by a magnet. About 1892 the idea occurred to him of using vacuum-jacketed vessels for the storage of liquid gases, and so efficient did this device prove in preventing the influx of external heat that it is found possible not only to preserve the liquids for comparatively long periods, but also to keep them so free from ebullition that examination of their optical properties becomes possible. He next experimented with a high-pressure hydrogen jet by which low temperatures were realized through the Thomson-Joule effect, and the successful results thus obtained led him to build the large refrigerating machine by which in 1898 hydrogen was for the first time collected in the liquid state, its solidification following in 1899 (see LIQUID GASES). The Royal Society in 1894 bestowed the Rumford Medal upon Professor Dewar for his work in the production of low temperatures, and in 1899 he became the first recipient of the Hodgkins Gold Medal of the Smithsonian Institution, Washington, for his contributions to our knowledge of the nature and properties of atmospheric air.

**Dewas,** a native state of India, in the Indore agency. For more than a century the state has been divided, almost equally, between the descendants of a former chief, known as the senior and junior branches, or as Baba and Dada Saheb. Both live in the town of Dewas, but exercise exclusive jurisdiction over their several shares. Total area, 289 square miles. Population (1881), 142,162; (1891), 152,073, showing an increase of 7 per cent., which has been almost confined to the share of the senior branch; average density, 526 persons per square mile. The chiefs are Rajputs of the Puar clan, of the same family as the Raja of Dhar. The two chiefs ruling in 1901 were named Krishnaji Rao and Mulhar Rao, these names showing Maratha influence.

The town of DEWAS is situated in 22° 58′ N. lat. and 76° 6′ E. long., about 20 miles north-east of Indore. Population, 11,921. It has a high school and a hospital.

**Dewey, George** (1837– ——), American naval commander, was born in Montpelier, Vt., on 26th December 1837, and graduated at the U.S. Naval Academy in 1858. In the Civil War he served as lieutenant on the steam sloop *Mississippi*, during Farragut's passage of the forts below New Orleans in April 1862, and at Port Hudson in March 1863. After the war he performed various routine duties, rising in grade to commodore (February 1896). On 30th November 1897 he was assigned, at his own request, to sea service, and sent to Asiatic waters. Being notified by telegraph in April 1898, while with his fleet at Hong Kong, that war had been declared with

Spain, and ordered to "capture or destroy the Spanish fleet" at the Philippines, he departed for Manila with his squadron, after procuring coal and provisions for the expedition. Steaming into Manila harbour, his fleet advanced on 1st May at early dawn against the Spanish vessels sighted at the other end of the bay. His flagship, the *Olympia*, led in a fight at close range which lasted, with slight intermission, until the afternoon, when the last Spanish flag was hauled down. The surrender of the city of Manila followed later. After remaining in the Philippines under orders from his Government to main tain control, Dewey returned home, October 1899, receiving great ovations. He was advanced to rear-admiral, with the thanks of Congress, soon after his victory, and was promoted to admiral on 2nd March 1899.

**Dewsbury,** a municipal and parliamentary borough and market-town of Yorkshire, England, on the Calder, 7 miles east-north-east of Huddersfield by rail. The old church of All Saints has been enlarged; besides, there are five Established, a Roman Catholic, and several Nonconformist churches, grammar and technical schools, an infirmary, and, of recent erection, a town-hall, a free library, and public baths. The hall and library in the buildings of an industrial co-operative society also deserve mention. A public park was opened in 1893. There are iron foundries and works for machinery. Area of municipal borough, 1468 acres. Population (1881), 29,637; (1901), 28,050.

**Dhar,** a native state of India, in the Bhopawar agency, Central India, includes many Rajput and Bhil feudatories, and has an area of 1740 square miles. In 1881 it had a population of 151,877, and in 1891 of 169,474, showing an average density of 98 persons per square mile. The revenue in 1897–98 was Rs.8,57,909; the police force numbered 1015 men. The state includes the ruins of Mandu, or Mandogarh, the Mahommedan capital of Malwa.

The town of DHAR is 33 miles west of Mhow, 908 feet above the sea. Population, about 15,000. It is a centre of the opium trade, and has a high school and hospital.

**Dharampur,** a native state of India, in the Gujarat division of Bombay, with an area of 794 square miles. The population in 1881 was 101,289; in 1891 it was 120,498; the estimated gross revenue was Rs.4,12,712, of which Rs.88,000 was expended in public works in 1897–98; the tribute is Rs.9000. The state has been surveyed for land revenue on the Bombay system. The number of police was 170; the number of schools was 20, with 940 pupils in 1897–98. The population of Dharampur town in 1891 was 4775.

**Dharwar,** a town and district of British India, in the Carnatic or Canarese-speaking division of Bombay, with a railway station. The population in 1881 was 27,191; in 1891 it was 32,841. It has two ginning factories and a cotton-mill with 10,000 spindles, employing 200 hands; two high schools, one maintained by the Government and the other by the Basel German Mission, with 466 pupils in 1896–97; training schools for masters and for mistresses; fourteen printing-presses, eleven of which issue periodicals in Canarese and Mahratti.

The DISTRICT OF DHARWAR has an area of 4603 square miles. In 1881 it had a population of 893,587, and in 1891 of 1,051,314, giving an average density of 228 persons per square mile. In 1901 the population was 1,113,426, showing an increase of 6 per cent. The land revenue and rates were Rs.33,01,157, the incidence of assessment being R.1–3–5 per acre; the cultivated area in 1897–98 was 2,076,808 acres, of which 94,323 were irrigated from tanks, &c., including 4381 acres from Government canals; the number of police was 945; the children at school in 1897–98 numbered 34,298, being 3·4 per cent. of the total population; the death-rate in 1897 was 37·57 per thousand. The principal crops are millets, pulse, and cotton. The centres of the cotton trade are Hubli and Gadak, junctions on the Southern Mahratta Railway, which now traverses the district in several directions.

**Dholpur,** a native state of India, in the Rajputana agency, with an area of 1156 square miles. The population in 1881 was 249,657; in 1891 it was 279,980, giving an average density of 242 persons per square mile. In 1901 the population was 271,496, showing a decrease of 3 per cent. The estimated revenue is Rs.12,50,000. There were six schools, with 366 pupils, in 1897–98; and four dispensaries, attended by 25,843 patients. The state is crossed by the Indian Midland Railway from Jhansi to Agra. In recent years it has suffered severely from drought. In 1896–97 the expenditure on famine relief amounted to Rs.1,22,859.

The town of DHOLPUR is 34 miles south of Agra by rail. Population, about 16,000.

**Dhrangadra,** a native state of India, in the Gujarat division of Bombay, situated in the north of the peninsula of Kathiawar. Its area is 1156 square miles. The population in 1881 was 99,686, and in 1891 was 103,754; the estimated gross revenue is Rs.5,75,110, of which Rs.25,790 was expended on public works in 1897–98; the tribute is Rs.44,677. A railway on the metre gauge from Wadhwan to the town of Dhrangadra (21 miles) was opened for traffic in 1898.

The town of DHRANGADRA is situated in 22° 59′ N. lat. and 71° 31′ E. long. There is a printing-press, issuing an official gazette. Population (1891), 15,209.

**Dhuleep Singh** (1837–1893), Maharajah of Lahore, was born in February 1837, and was proclaimed Maharajah on 18th September 1843, under the regency of his mother the Ranee Jinda, a woman of great capacity and strong will, but extremely inimical to the British. He was acknowledged by Runjeet Singh and recognized by the British Government. After six years of peace the Sikhs invaded British territory in 1845, but were defeated in four battles, and terms were imposed upon them at Lahore, the capital of the Punjab. Dhuleep Singh retained his territory, but it was administered to a great extent by the British Government in his name. This arrangement increased the Regent's dislike of the British, and a fresh outbreak occurred in 1848–49. In spite of the valour of the Sikhs, they were utterly routed at Gujarat, and in March 1849 Dhuleep Singh was deposed, a pension of £40,000 a year being granted to him and his dependants. He became a Christian and elected to live in England. On coming of age he made an arrangement with the Government by which his income was reduced to £25,000 in consideration of advances for the purchase of an estate, and he finally settled at Elvedon in Suffolk. While passing through Alexandria in 1864 he met Miss Bamba Muller, the daughter of a German merchant who married an Abyssinian. The Maharajah had been interested in mission work by Sir John Login, and he met Miss Muller at one of the missionary schools where she was teaching. She became his wife on 7th June 1864, and six children were the issue of the marriage. In the year after her death in 1890 the Maharajah married at Paris, as his second wife, an English lady, Miss Ada Douglas Wetherill, who survived him. The Maharajah was passionately fond of sport, and his shooting parties were celebrated, while he himself became a *persona grata* in English society. The result, however, was financial difficulty, and in 1882 he appealed to the Government for

assistance, making various claims based upon the alleged possession of private estates in the Punjab, and upon the surrender of the Kohinoor diamond to the English Crown. His demand was rejected, whereupon he started for India, after drawing up a proclamation to his former subjects. But as it was deemed inadvisable to allow him to visit the Punjab, he remained for some time as a guest at the residency at Aden, and was allowed to receive some of his relatives to witness his abjuration of Christianity, which actually took place within the residency itself. As the climate began to affect his health, the Maharajah at length left Aden and returned to Europe. He stayed for some time in Russia, hoping that his claim against England would be taken up by the Russians; but when that expectation proved futile he proceeded to Paris, where he lived for the rest of his life on the pension allowed him by the Indian Government. His death from an attack of apoplexy took place at Paris, 22nd October 1893. (G. F. B.)

**Dhulia,** a town of British India, administrative headquarters of Khandesh district in Bombay, on the right bank of the Panjhra river. The population in 1881 was 18,449; in 1891 it was 21,880. It has cantonments for the Bhil Corps and a detachment of the Poona Horse. Considerable trade is done in cotton and oil-seeds, and weaving of cotton. It contains the Garud High School, with 348 pupils in 1896–97, and five printing-presses, each issuing a vernacular newspaper. A railway to connect Dhulia with Chalisgaon, on the main line of the Great Indian Peninsula (37 miles), was commenced in 1900.

**Diabetes.** See PATHOLOGY (*Metabolic Diseases*).

**Diamantina,** a town of Brazil, in the state of Minas Geraes, with a population of 13,000, is the centre of the diamond mine district, and yields the larger part of the production of diamonds in Brazil, which is estimated at 40,000 carats a year.

**Diarbekr.**—I. A viláyet of Asiatic Turkey through which the western arm of the Tigris flows. It extends southwards from Palu, on the Euphrates, to Mardin and Nisibin, and is divided into three sanjaks—Arghana, Diarbekr, and Mardin. Cereals, cotton, tobacco, rice, and silk are produced; but most of the fertile lands have been abandoned to the nomads and semi-nomads, who raise large quantities of live-stock. Copper, galena, mineral oil, and silicious sand are found. The population is about 480,000 (Moslems, including nomad and semi-nomad Kúrds, 336,000; Yezidis and Gypsies, 4000; Christians, chiefly Armenians and Syrians, 139,000; Jews, 1000). II. The chief town of the viláyet and of a sanjak of the same name (the ancient Amida), seat of a Governor-General, headquarters of a military district, situated at an altitude of 1950 feet, on a high mass of basalt rock on the right bank of the Tigris, which is here crossed by a stone bridge and is fordable in several places in winter. Its position at the head of raft navigation on the Tigris, and with easy roads to Alexandretta on the Mediterranean, Samsún on the Black Sea, Erzerúm, Bitlis, and Mosul, has always been one of commercial and strategic importance. Old walls, pierced by four gates, and standing above cliffs from 20 to 40 feet high, surround the town, and beneath them, on the river side, are irrigated gardens. At the north-east angle, on the highest ground, are the ruins of a citadel, in which is the Serai or Government House. The streets are narrow, badly paved, and filthy. The houses are low, and built partly of black basalt—whence the ancient name of the town, Kara (black) Amid—and partly of dark coloured sun-dried bricks. In the great mosque, Ulu Jami' and its court are the façades of two Sassanian palaces, apparently built with materials from an older palace, perhaps that of Tigranes II. The churches of SS. Cosmas and Damian (Jacobite) and St James (Greek) are also of interest. The climate in winter is good; snow often lies, and there is sufficient ice for storage for summer use. In summer it is very hot and unhealthy. Epidemics of typhus are frequent, and ophthalmia and the "Aleppo button" are common. Scorpions, noted for the virulence of their poison, abound. There are a few small industries, silver filigree work, morocco leather, cotton, and silk. Fruit is grown near the town, but little of the adjoining land is cultivated. The principal exports are wool, mohair, copper ore, &c.; and the imports, cotton and woollen goods, indigo, coffee, sugar, petroleum, &c. The population is 25,000 (Turks, Kúrds, and Arabs, 13,000; Armenians, Jacobites, Greeks, Protestants, and Jews, 12,000). During the massacres of 1895 the Christians successfully defended themselves against the Moslems. (C. W. W.)

**Diaz, Narcisse Virgilio** (1808–1876), French painter, was born in Bordeaux of Spanish parents, 25th August 1808. At first a figure-painter who indulged in strong colour, in his later life Diaz became a painter of the forest and a "tone artist" of the first order. He spent much time at Barbizon; and although he is the least exalted of the half-dozen great artists who are usually grouped round that name, he sometimes produced works of the highest quality. At the age of ten Diaz became an orphan, and misfortune dogged his earlier years. His foot was bitten by a reptile in Meudon wood, near Sèvres, where he had been taken to live with some friends of his mother. The bite was badly dressed, and ultimately it cost him his leg. Afterwards his wooden stump became famous. At fifteen he entered the studios at Sèvres, where the decoration of porcelain occupied him; but tiring of the restraint of fixed hours, he took to painting Eastern figures dressed in richly coloured garments. Turks and Oriental scenes attracted him, and many brilliant gems remain of this period. About 1831 Diaz encountered Théodore Rousseau, for whom he entertained a great veneration, although Rousseau was four years his junior; but it was not until ten years later that the remarkable incident took place of Rousseau teaching Diaz to paint trees. At Fontainebleau Diaz found Rousseau painting his wonderful forest pictures, and determined to paint in the same way if possible. Rousseau, then in poor health, worried at home, and embittered against the world, was difficult to approach. Diaz followed him surreptitiously to the forest,—wooden leg not hindering,—and he dodged round after the painter, trying to observe his method of work. After a time Diaz found a way to become friendly with Rousseau, and revealed his anxiety to understand his painting. Rousseau was touched with the passionate words of admiration, and finally taught Diaz all he knew. Diaz exhibited many pictures at the Paris Salon, and was decorated in 1851. During the war, twenty years later, he went to Brussels. After 1871 he became fashionable, his works gradually rose in the estimation of collectors, and he worked constantly and successfully. In 1876 he caught cold at his son's grave, and on 18th November of that year he died at Mentone, whither he had gone to recruit his health. Diaz's finest pictures are his forest scenes and storms, and it is on these, and not on his pretty figures, that his fame is likely to rest. There are several fairly good examples of the master in the Louvre, and three small figure pictures in the Wallace Collection, Hertford House. Perhaps the most notable of Diaz's works are "La Fée aux Perles" (1857), in the Louvre; "Sunset in the Forest" (1868);

"The Storm," and "The Forest of Fontainebleau" (1870) at Leeds. Diaz had no well-known pupils, but Léon Richet followed markedly his methods of tree-painting, and J. F. Millet (*q.v.*) at one period painted small figures in avowed imitation of Diaz's then popular subjects.

**Diaz, Porfirio** (1830-——), President of the Republic of Mexico, was born at Oaxaca 15th September 1830. He was educated for the Church, but upon becoming his own master decided to follow the profession of the law; and, about 1855, the disturbed condition of the country, in revolt against Santa Anna, made him a soldier. He took a prominent part in the resistance to the French invasion in 1863, and so greatly distinguished himself as to have become by 1867 commander of the army of the east, to which the capital surrendered after the execution of the Emperor Maximilian. He then retired into private life, but in 1870–72 was in arms against President Juarez, and in 1875 placed himself at the head of an insurrection against the Government of President Lerdo de Tejada. After many desperate struggles and hairbreadth escapes he entered the city of Mexico in November 1876, and was elected President in 1877. His repudiation of all the promises he had made in the programme he had put forward at the beginning of the civil war caused his term of office to be exceedingly stormy, but he suppressed all opposition, and in 1880 peacefully transmitted his power to General Gonzalez, his Secretary of War. In 1884 he was elected for a second term, and, the provision of the Constitution which forbade the re-election of a President having been repealed, he continued to be regularly re-elected; and no disquieting event has since occurred, except an abortive attempt to assassinate him in 1897. Under his vigorous rule the most anarchical of Spanish American states has become the most orderly; military revolts have disappeared; the laws are executed without opposition; industry has been stimulated, to the great increase of national wealth; roads and railways have been multiplied; foreign capital has been invested and rendered secure; and the financial credit of the country, which had sunk to the lowest ebb, has been entirely re-established. All these benefits are owing to General Diaz's force of character and administrative ability, and he has incontestably earned the title of the regenerator of Mexico.

**Dibrugarh,** a town of British India, in the Lakhimpur district of Assam, of which it is the headquarters, situated on the Dibru river about 4 miles above its confluence with the Brahamaputra. In 1881 it had a population of 7153, and in 1891 of 9876. It is the terminus of steamer navigation on the Brahmaputra, and also of a railway running to important coal-mines and petroleum wells, which will ultimately be connected with the Assam-Bengal system. Large quantities of coal and tea are exported. There are a military cantonment, with 280 men in 1898; the headquarters of the volunteer corps known as the Assam Valley Light Horse; a Government high school, with 292 pupils in 1896–97; a training school for masters; and an aided school for girls. In 1900 a medical school for the province was established, out of a bequest of Rs.50,000 left by the late Brigade-Surgeon J. Berry-White, which will be maintained by the Government, to train hospital assistants for the tea gardens. The Williamson Artisan School is entirely supported by an endowment. There are three printing-presses.

**Dictionary.**—A dictionary is a book in which the words of a language, or words of a special class, are arranged, generally in alphabetical order, and their meaning and idiomatic use are explained in the same or in a different language. Most modern dictionaries give also the pronunciation of the words defined and an account of their derivation or etymology, and some add information of various kinds about the things or processes which certain words designate. If the latter variety are general (not limited to a special class of words) they are commonly called *encyclopædic.* A general dictionary in which the information given relates only to the meaning, idiomatic use, pronunciation, orthography, derivation, and history of words (or to some of these things) is literary, pedagogical, or philological. Special dictionaries are classed as *technical* when they include only the terms of one or more of the sciences, arts, or trades. The name is also given to certain works, such as a "rhyming dictionary," a "dictionary of biography," a "dictionary of quotations," and the like, which are not of a strictly lexicographic character, and to encyclopædias. For a detailed description of dictionaries of various kinds, and for a list of the more important of them, the reader is referred to the article in the ninth edition of this work, vol. vii. (pp. 179–193). Here only the more noteworthy recent work in general lexicography will be considered.

At no time has progress in the making of general dictionaries been so rapid as during the second half of the 19th century. It is to be seen in three things: in the perfecting of the theory of what a general dictionary should be; in the elaboration of methods of collecting and editing lexicographic materials; and in the magnitude and improved quality of the work which has been accomplished or planned. Each of these can best be illustrated from English lexicography, in which the process of development has in all directions been carried farthest. The advance that has been made in theory began with a radical change of opinion with regard to the chief end of the general dictionary of a language. The older view of the matter was that the lexicographer should furnish a standard of usage—should register only those words which are, or at some period of the language have been, "good" from a literary point of view, with their "proper" senses and uses, or should at least furnish the means of determining what these are. In other words, his chief duty was conceived to be to sift and refine, to decide authoritatively questions with regard to good usage, and thus to fix the language as completely as might be possible within the limits determined by the literary taste of his time. Thus the Accademia della Crusca, founded near the close of the 16th century, was established for the purpose of purifying in this way the Italian tongue, and in 1612 the *Vocabolario degli Accademici della Crusca,* long the standard of that language, was published. The Académie Française, the first edition of whose dictionary appeared in 1694, had a similar origin. In England the idea of constructing a dictionary upon this principle arose during the second quarter of the 18th century. It was imagined by men of letters—among them Alexander Pope—that the English language had then attained such perfection that further improvement was hardly possible, and it was feared that if it were not fixed by lexicographic authority deterioration would soon begin. Since there was no English "Academy," it was necessary that the task should fall to some one whose judgment would command respect, and the man who undertook it was Samuel Johnson. His dictionary, the first edition of which, in two

folio volumes, appeared in 1755, was in many respects admirable, but it was inadequate even as a standard of the then existing literary usage. Johnson himself did not long entertain the belief that the natural development of a language can be arrested in that or in any other way. His work was, however, generally accepted as a final authority, and the ideas upon which it was founded dominated English lexicography for more than a century. The first effective protest, in England, against the supremacy of this literary view was made by Dean (later Archbishop) Trench, in a paper on "Some Deficiencies in Existing English Dictionaries" read before the Philological Society in 1857. "A dictionary," he said, "according to that idea of it which seems to me alone capable of being logically maintained, is an *inventory of the language;* much more, but this primarily. . . . It is no task of the maker of it to select the *good* words of the language. . . . The business which he has undertaken is to collect and arrange *all* words, whether good or bad, whether they commend themselves to his judgment or otherwise. . . . *He is an historian of* [the language], *not a critic.*" That is, for the literary view of the chief end of the general dictionary should be substituted the philological or scientific. In Germany this substitution had already been effected by Jacob and Wilhelm Grimm in their dictionary of the German language, the first volume of which appeared in 1854. In brief, then, the modern view is that the general dictionary of a language should be a record of all the words—current or obsolete—of that language, with all their meanings and uses, but should not attempt to be, except secondarily, or indirectly, a guide to "good" usage. A "standard" dictionary has, in fact, been recognized to be an impossibility, if not an absurdity.

This theoretical requirement must, of course, be modified considerably in practice. The date at which a modern language is to be regarded by the lexicographer as "beginning" must, as a rule, be somewhat arbitrarily chosen; while considerable portions of its earlier vocabulary cannot be recovered because of the incompleteness of the literary record. Moreover, not even the most complete dictionary can include all the words which the records—earlier and later—actually contain. Many words, that is to say, which are found in the literature of a language cannot be regarded as, for lexicographic purposes, belonging to that language; while many more may or may not be held to belong to it, according to the judgment—almost the whim—of the individual lexicographer. This is especially true of the English tongue. "That vast aggregate of words and phrases which constitutes the vocabulary of English-speaking men presents, to the mind that endeavours to grasp it as a definite whole, the aspect of one of those nebulous masses familiar to the astronomer, in which a clear and unmistakable nucleus shades off on all sides, through zones of decreasing brightness, to a dim marginal film that seems to end nowhere, but to lose itself imperceptibly in the surrounding darkness" (Dr J. A. H. Murray, *Oxford Dict.*, General Explanations, p. xvii). This "marginal film" of words with more or less doubtful claims to recognition includes thousands of the terms of the natural sciences (the New-Latin classificatory names of zoology and botany, names of chemical compounds and of minerals, and the like); half-naturalized foreign words; dialectal words; slang terms; trade names (many of which have passed or are passing into common use); proper names and many more. Many of these even the most complete dictionary should exclude; others it should include; but where the line shall be drawn will always remain a vexed question.

Another important principle upon which Trench insisted, and which also expresses a requirement of modern scientific philology, is that the dictionary shall be not merely a record, but also an *historical* record of words and their uses. From the literary point of view the most important thing is present usage. To that alone the idea of a "standard" has any application. Dictionaries of the older type, therefore, usually make the common, or "proper," or "root" meaning of a word the starting-point of its definition, and arrange its other senses in a logical or accidental order, commonly ignoring the historical order in which the various meanings arose. Still less do they attempt to give data from which the vocabulary of the language at any previous period may be determined. The philologist, however, for whom the growth, or progressive alteration, of a language is a fact of central importance, regards no record of a language as complete which does not exhibit this growth in its successive stages. He desires to know when and where each word, and each form and sense of it, are first found in the language; if the word or sense is obsolete, when it died; and any other fact that throws light upon its history. He requires, accordingly, of the lexicographer that, having ascertained these data, he shall make them the foundation of his exposition—in particular, of the division and arrangement of his definitions, that sense being placed first which appeared first in order of time. In other words, each article in the dictionary should furnish an orderly biography of the word of which it treats, each word and sense being so dated that the exact time of its appearance and the duration of its use may as nearly as possible be determined. This, in principle, is the method of the new lexicography. In practice it is subject to limitations similar to those of the vocabulary mentioned above. Incompleteness of the early record is here an even greater obstacle; and there are many words whose history is, for one reason or another, so unimportant that to treat it elaborately would be a waste of labour and space.

The adoption of the historical principle involves a further noteworthy modification of older methods, namely, an important extension of the use of quotations. To Dr Johnson belongs the credit of showing how useful, when properly chosen, they may be, not only in corroborating the lexicographer's statements, but also in revealing special shades of meaning or variations of use which his definitions cannot well express. No part of Johnson's work is more valuable than this. This idea was more fully developed and applied by Dr Charles Richardson, whose *New Dictionary of the English Language . . . Illustrated by Quotations from the Best Authors* (1835–36), still remains a most valuable collection of literary illustrations. Lexicographers, however, have, with few exceptions, until a recent date, employed quotations chiefly for the ends just mentioned—as instances of use or as illustrations of correct usage—with scarcely any recognition of their value as historical evidence; and they have taken them almost exclusively from the works of the "best" authors. But since all the data upon which conclusions with regard to the history of a word can be based must be collected from the literature of the language, it is evident that, in so far as the lexicographer is required to furnish evidence for an historical inference, a quotation is the best form in which he can give it. In fact, extracts, properly selected and grouped, are generally sufficient to show the entire meaning and biography of a word without the aid of elaborate definitions. The latter simply save the reader the trouble of drawing the proper conclusions for himself. A further rule of the new lexicography, accordingly, is that quotations should be used, primarily, as historical evidence, and that the history of words and meanings should be exhibited by means of them. The earliest instance of use that can be found, and (if the word or sense is obsolete) the latest, are as a rule to be given; while in the case of an important

word or sense, instances taken from successive periods of its currency also should be cited. Moreover, a quotation which contains an important bit of historical evidence must be used, whether its source is "good," from the literary point of view, or not—whether it is a classic of the language or from a daily newspaper; though where choice is possible, preference should, of course, be given to quotations extracted from the works of the best writers. This rule does not do away with the illustrative use of quotations, which is still recognized as highly important, but it subordinates it to their historical use. It is necessary to add that it implies that the extracts must be given exactly and in the original spelling and capitalization, accurately dated, and furnished with a precise reference to author, book, volume, page, and edition; for insistence upon these requirements—which are obviously important, whatever the use of the quotation may be—is one of the most noteworthy of modern innovations. Johnson usually gave simply the author's name, and often quoted from memory and inaccurately; and many of his successors to this day have followed—altogether or to some extent—his example.

The chief difficulty in the way of this use of quotations —after the difficulty of collection—is that of finding space for them in a dictionary of reasonable size. Preference must be given to those which are essential, the number of those which are cited merely on methodical grounds being made as small as possible. It is hardly necessary to add that the negative evidence furnished by quotations is generally of little value; one can seldom, that is, be certain that the lexicographer has actually found the earliest or the latest use, or that the word or sense has not been current during some intermediate period from which he has no quotations.

Lastly, a much more important place in the scheme of the ideal dictionary is now assigned to the *etymology* of words. This may be attributed, in part, to the recent rapid development of etymology as a science, and to the greater abundance of trustworthy data; but it is chiefly due to the fact that from the historical point of view the connexion between that section of the biography of a word which lies within the language—subsequent, that is, to the time when the language may, for lexicographical purposes, be assumed to have begun, or to the time when the word was adopted or invented—and its antecedent history has become more vital and interesting. Etymology, in other words, is essentially the history of the *form* of a word up to the time when it became a part of the language, and is, in a measure, an extension of the history of the development of the word in the language. Moreover, it is the only means by which the exact relations of allied words can be ascertained, and the separation of words of the same form but of diverse origin (homonyms) can be effected, and is thus, for the dictionary, the foundation of all *family history* and correct *genealogy*. In fact, the attention that has been paid to these two points in the best recent lexicography is one of its distinguishing and most important characteristics. Related to the etymology of words are the changes in their form which may have occurred while they have been in use as parts of the language—modifications of their pronunciation, corruptions by popular etymology or false associations, and the like. The facts with regard to these things which the wide research necessitated by the historical method furnishes abundantly to the modern lexicographer are often among the most novel and interesting of his acquisitions.

It should be added that even approximate conformity to the theoretical requirements of modern lexicography as above outlined is possible only under conditions similar to those under which the *Oxford English Dictionary* was undertaken (see below). The labour demanded is too vast, and the necessary bulk of the dictionary too great. When, however, a language is recorded in one such dictionary, those of smaller size and more modest pretensions can rest upon it as an authority and conform to it as a model so far as their special limitations permit.

The ideal thus developed is primarily that of the general dictionary of the purely philological type, but it applies also to the encyclopædic dictionary. In so far as the latter is strictly lexicographic—deals with words as words, and not with the things they denote—it should be made after the model of the former, and is defective to the extent in which it deviates from it. The addition of encyclopædic matter to the philological in no way affects the general principles involved. It may, however, for practical reasons, modify their application in various ways. For example, the number of obsolete and dialectal words included may be much diminished and the number of scientific terms (for instance, New-Latin botanical and zoological names) be increased; and the relative amount of space devoted to etymologies and quotations may be lessened. In general, since books of this kind are designed to serve more or less as works of general reference, the making of them must be governed by considerations of practical utility which the compilers of a purely philological dictionary are not obliged to regard. The encyclopædic type itself, although it has often been criticized as hybrid—as a mixture of two things which should be kept distinct—is entirely defensible. Between the dictionary and the encyclopædia the dividing-line cannot sharply be drawn. There are words the meaning of which cannot be explained fully without some description of things, and, on the other hand, the description of things and processes often involves the definition of names. To the combination of the two objection cannot justly be made, so long as it is effected in a way—with a selection of material—that leaves the dictionary essentially a dictionary and not an encyclopædia. Moreover, the large vocabulary of the general dictionary makes it possible to present certain kinds of encyclopædic matter with a degree of fulness and a convenience of arrangement which are possible in no single work of any other class. In fact, it may be said that if the encyclopædic dictionary did not exist it would have to be invented; that its justification is its indispensableness. Not the least of its advantages is that it makes legitimate the use of diagrams and pictorial illustrations, which, if properly selected and executed, are often valuable aids to definition.

**Practical methods of modern lexicography.**

On its practical side the advance in lexicography has consisted in the elaboration of methods long in use rather than in the invention of new ones. The only way to collect the data upon which the vocabulary, the definitions, and the history are to be based is, of course, to search for them in the written monuments of the language, as all lexicographers who have not merely borrowed from their predecessors have done. But the wider scope and special aims of the new lexicography demand that the investigation shall be vastly more comprehensive, systematic, and precise. It is necessary, in brief, that, as far as may be possible, the literature (of all kinds) of every period of the language shall be examined systematically, in order that all the words, and senses and forms of words, which have existed during any period may be found, and that enough excerpts (carefully verified, credited, and dated) to cover all the essential facts shall be made. The books, pamphlets, journals, newspapers, and so on which must thus be searched will be numbered by thousands, and the quotations selected may (as in the case of the *Oxford Dictionary*) be counted by millions. This task is beyond the powers of any one man, even though he be a Johnson, or a Littré,

or a Grimm, and it is now assigned to a corps of readers whose number is limited only by the ability of the editor to obtain such assistance. The modern method of editing the material thus accumulated—the actual work of compilation — also is characterized by the application of the principle of the division of labour. Johnson boasted that his dictionary was written with but little assistance from the learned, and the same was in large measure true of that of Littré. Such attempts on the part of one man to write practically the whole of a general dictionary are no longer possible, not merely because of the vast labour and philological research necessitated by modern aims, but more especially because the immense development of the vocabulary of the special sciences renders indispensable the assistance, in the work of definition, of persons who are expert in those sciences. The tendency, accordingly, has been to enlarge greatly the editorial staff of the dictionary, scores of sub-editors and contributors being now employed where a dozen or fewer were formerly deemed sufficient. In other words, the making of a "complete" dictionary has become a co-operative enterprise, to the success of which workers in all the fields of literature and science contribute.

The most complete exemplification of these principles and methods is the *Oxford English Dictionary*. It originated in the suggestion of Trench that an attempt should be made, under the direction of the Philological Society, to complete the vocabulary of existing dictionaries and to supply the historical information which they lacked. The suggestion was adopted, considerable material was collected, and Mr Herbert Coleridge was appointed general editor. He died in 1861, and was succeeded by Mr F. J. Furnivall. Little, however, was done, beyond the collection of quotations—about two millions of which were gathered—until in 1878 the expense of printing and publishing the proposed dictionary was assumed by the Delegates of the Clarendon Press, and the editorship was entrusted to Dr J. A. H. Murray. From that time the work has been carried on with vigour and increasing rapidity, and it will probably be completed about 1912. As the historical point of beginning, the middle of the 12th century was selected, all words that were obsolete at that date being excluded, though the history of words that were current both before and after that date is given in its entirety; and it was decided that the search for quotations—which, according to the original design, was to cover the entire literature down to the beginning of the 16th century and as much of the subsequent literature (especially the works of the more important writers and works on special subjects) as might be possible—should be made more thorough. More than 800 readers, in all parts of the world, offered their aid; and when the preface to the first volume appeared in 1888, the editor was able to announce that the readers had increased to 1300, and that three and one-half millions of quotations, taken from the writings of more than five thousand authors, had been amassed: numbers which must now be very greatly enlarged. The first part was issued in 1884, and up to April 1901 somewhat less, probably, than one-half of the work had appeared (to the word *Lap*, with the exception of the letter *K*; in five volumes and the first part of the sixth). The number of "main words," "subordinate words," and "special combinations" (the last term including a very large number of ordinary compounds, loose compounds, and phrases) defined in these published portions is given as 148,413, a figure which indicates a total for the whole dictionary of considerably more than 300,000. When this is compared with the 40,000 words (about) registered by Johnson, the progress made in the direction of completeness will be evident. Completeness, however, is less important than quality of work, and for this the dictionary is equally notable. The historical method of exposition, particularly by quotations, is applied, if not in all cases with entire success, yet, on the whole, with a regularity and a precision which leave little to be desired. A minor fault is that excerpts from second or third rate authors have occasionally been used where better ones from writers of the first class either must have been at hand or could have been found. As was said above, the literary quality of the quotation is highly important even in historical lexicography, and should not be neglected unnecessarily. Other special features of the book are the completeness with which variations of pronunciation and orthography (with dates) are given; the fulness and scientific excellence of the etymologies, which abound in new information and corrections of old errors; the phonetic precision with which the present (British) pronunciation is indicated; and the elaborate subdivision of meanings. The definitions as a whole are marked by a high degree of accuracy. Work of such magnitude and quality is possible, practically, only when the editor of the dictionary can command not merely the aid of a very large number of scholars and men of science, but their gratuitous aid. In this the *Oxford Dictionary* has been singularly fortunate. The conditions under which it originated, and its aim, have interested scholars everywhere, and led them to contribute to the perfecting of it their knowledge and time. The long list of names of such helpers in Dr Murray's preface is in curious contrast with their absence from Dr Johnson's and the few which are given in that of Littré. Of the dictionary as a whole it may be said that it is one of the greatest achievements, whether in literature or science, of the Victorian Age.

The *Oxford Dictionary* furnishes for the first time data from which the extent of the English word-store at any given period, and the direction and rapidity of its growth, can fairly be estimated. For this purpose the materials furnished by the older dictionaries are quite insufficient, on account of their incompleteness and unhistorical character. For example, one hundred pages of the *Oxford Dictionary* (from the letter H) contain 1002 words, of which, as the dated quotations show, 585 were current in 1750 (though some, of course, were very rare, some dialectal, and so on), 191 were obsolete at that date, and 226 have since come into use. But of the more than 700 words — current or obsolete — which Johnson might thus have recorded, he actually did record only about 300. Later dictionaries give more of them, but they in no way show their status at the date in question. It is worth noting that the figures given seem to indicate that not very many more words have been added to the vocabulary of the language during the past one hundred and fifty years than had been lost by 1750. The pages selected, however, contain comparatively few recent scientific terms. A broader comparison would probably show that the gain has been more than twice as great as the loss.

In the *Deutsches Wörterbuch* of Jacob and Wilhelm Grimm the scientific spirit, as was said above, first found expression in general lexicography. The desirability of a complete inventory and investigation of German words was recognized by Leibnitz and by various 18th-century scholars, but the plan and methods of the Grimms were the direct product of the then new scientific philology. Their design, in brief, was to give an exhaustive account of the words of the literary language (New High German) from about the end of the 15th century, including their earlier etymological and later history, with references to important dialectal words and forms; and to illustrate their use and history abundantly by quotations. The first volume appeared in 1854. At the present time seven others have been completed, and one has nearly been finished, while parts of the remaining three (there are to be twelve in all) have been issued. Jacob Grimm (died 1863) edited the first, second (with his brother, who died in 1859), third, and a part of the fourth volumes; the others have been edited by various distinguished scholars. The scope and methods of this dictionary have been

broadened somewhat as the work has advanced. In general it may be said that it differs from the *Oxford Dictionary* chiefly in its omission of pronunciations and other pedagogic matter; its irregular treatment of dates; its much less systematic and less lucid statement of etymologies; its less systematic and less fruitful use of quotations; and its less convenient and less intelligible arrangement of material and typography.

These general principles lie also at the foundation of the scholarly *Dictionnaire de la langue française* of E. Littré, though they are there carried out less systematically and less completely. In the arrangement of the definitions the first place is given to the most primitive meaning of the word instead of to the most common one, as in the dictionary of the Academy; but the other meanings follow in an order that is often logical rather than historical. Quotations also are frequently used merely as literary illustrations, or are entirely omitted; in the special paragraphs on the history of words before the 16th century, however, they are put to a strictly historical use. This dictionary—perhaps the greatest ever compiled by one man—was published 1863–72. (Supplement, 1878.)

The *Thesaurus Linguae Latinae*, prepared under the auspices of the German Academies of Berlin, Göttingen, Leipzig, Munich, and Vienna, is a notable application of the principles and practical co-operative method of modern lexicography to the classical tongues. The plan of the work is to collect quotations which shall register, with its full context, every word (except the most familiar particles) in the text of each Latin author down to the middle of the 2nd century A.D., and to extract all important passages from all writers of the following centuries down to the 7th; and upon these materials to found a complete historical dictionary of the Latin language. The work of collecting quotations was begun in 1894, and the first part of the first volume has been published.

In the making of all of these great dictionaries (except, of course, the last) the needs of the general public as well as those of scholars have been kept in view. But the type to which the general dictionary designed for popular use has tended more and more to conform is the *encyclopædic*. This combination of lexicon and encyclopædia is exhibited in an extreme—and theoretically objectionable—form in the *Grand dictionnaire universel du XIX^e^ siècle* of Pierre Larousse. Besides common words and their definitions, it contains a great many proper names, with a correspondingly large number of biographical, geographical, historical, and other articles, the connexion of which with the strictly lexicographical part is purely mechanical. Its utility, which—notwithstanding its many defects—is very great, makes it, however, a model which will be copied in the future. Fifteen volumes were published 1866–76, and a much improved new edition (*Nouveau Larousse Illustré*) was being published during 1901–2.

The most notable work of this class, in English, is *The Century Dictionary*, edited by Professor W. D. Whitney, and published 1889–91 in six volumes, containing 7046 pages (large quarto). It conforms to the philological model in giving with great fulness the older as well as the present vocabulary of the language, and in the completeness of its etymologies; but it does not attempt to give the full history of every word within the language. Among its other more noteworthy characteristics are the inclusion of a great number of modern scientific and technical words, and the abundance of its quotations. The quotations are for the most part provided with references, but they are not dated. In the application of the encyclopædic method this dictionary is conservative, excluding, with a few exceptions, proper names, and restricting, for the most part, the encyclopædic matter to descriptive and other details which may legitimately be added to the definitions. Its pictorial illustrations are very numerous and well executed. In the manner of its compilation it is a good example of modern co-operative dictionary-making, being the joint product of a large number of specialists. Next to the *Oxford Dictionary* it is the most complete and scholarly of English lexicons.

Among the more important dictionaries of European languages that have appeared since the list given in the 9th ed. of the *Ency. Brit.* vol. vii. (pp. 183–193) was written are the following:—

ANNANDALE. *The Imperial Dictionary of the English Language*, by John Ogilvie, LL.D.; new edition by Charles Annandale, M.A., London, 1882; 4 volumes. An encyclopædic dictionary, which served in a manner as the foundation of the *Century Dictionary*.—STORMONTH and W. BAYNE. *A Dictionary of the English Language.* 1885.—MURRAY and BRADLEY. *The Oxford English Dictionary: A New English Dictionary on Historical Principles*; founded mainly on the materials collected by the Philological Society. Oxford, 1888 [1884].—WHITNEY. *The Century Dictionary: An Encyclopedic Lexicon of the English Language.* New York, 1889–91. See above.—PORTER. *Webster's International Dictionary of the English Language.* Springfield, Mass., 1890.—FUNK. *A Standard Dictionary of the English Language.* New York, 1894.—HUNTER. *The Encyclopedic Dictionary.* London and New York, 1879–88.—FENNELL. *The Stanford Dictionary of Anglicized Words and Phrases.* Cambridge, 1892.—TOLLER. *An Anglo-Saxon Dictionary based on Manuscript Collections of the late Joseph Bosworth, D.D.* Oxford, 1882–98.—SKEAT. *An Etymological Dictionary of the English Language.* Oxford, 1881.—WRIGHT. *The English Dialect Dictionary.* London. Vol. 1, A–C, 1898; vol. 2, D–G, 1900.—BRADLEY. *A Middle-English Dictionary by Francis Henry Stratman*; a new edition by Henry Bradley. Oxford, 1891.—MÄTZNER and BIELING. *Altenglische Sprachproben, nebst einem Wörterbuch.* Berlin, 1878—. This dictionary had been advanced as far as *Misteleven* in 1900.—BESCHERELLE. *Nouveau dictionnaire national, ou dictionnaire universel de la langue française.* Paris, 1887.—GODEFROY. *Dictionnaire de l'ancienne langue française, et de tous ses dialectes du IX^e^ au XV^e^ siècle.* Paris, 1881–95; *Complément*, 1895—.—HATZFELD, DARMESTETER, and THOMAS. *Dictionnaire général de la langue française.* Paris, 1890–1900.—LARIVE et FLEURY. *Dictionnaire français illustré des mots et des choses.* Paris, 1884–91.—PETROCCHI. *Novo dizionario universale della lingua italiana.* Milan, 1884–91.—CUERVO. *Diccionario de construccion y regimen de la lengua castellana.* A–B (1886): C–D (1894).—MONLAU. *Diccionario etimológico de la lengua castellana.* Madrid, 1881.—ZEROLA, TORO Y GOMES, and ISAZA. *Diccionario enciclopédico de la lengua castellana.* Paris, 1895.—SERRANO. *Diccionario universal de la lengua castellana, ciencias, y artes: enciclopedia de los conocimientos humanos.* Madrid, 1876–81.—BARCIA. *Primer diccionario general etimológico de la lengua española.* Madrid, 1881–83.—SANDERS. *Ergänzungs-Wörterbuch der deutschen Sprache.* Berlin, 1885.—KLUGE. *Etymologisches Wörterbuch der deutschen Sprache.* Strassburg, 1883.—HEYNE. *Deutsches Wörterbuch.* Leipzig, 1890–95.—DIEFENBACH and WÜLCHER. *Hoch-und niederdeutsches Wörterbuch der mittleren und neueren Zeit. In Ergänzung der vorhandenen Wörterbücher, insbesondere das der Brüder Grimm.* Basel, 1885.—WEIGAND. *Deutsches Wörterbuch.* Giessen, 1873.—SCHADE. *Altdeutsches Wörterbuch.* Halle, 1872–82.—KALKAR. *Ordbog til det ældre Danske Sprog.* Copenhagen. (Incomplete.)—DALE. *Groot Woordenboek der Nederlandsche taal.* s'Gravenhage, 1898 (4th ed.).—VRIES and WINKEL. *Woordenboek der Nederlandsche taal.* s'Gravenhage, 1882—.—VERWIJS and VERDAM. *Middelnederlandsch Woordenboek.* s'Gravenhage, 1885–99 (A–N).—FRANCK. *Etymologische Woordenboek der Nederlandsche taal.* 1884–92.—EVANS. *Dictionary of the Welsh Language.* Carmarthen, 1887. (Incomplete.)—CLEASBY-VIGFUSSON. *An Icelandic-English Dictionary based on the MS. Collections of the late Richard Cleasby, enlarged and completed by Gudbrand Vigfusson, M.A.* Oxford, 1874.—MIKLOSICH. *Etymologisches Wörterbuch der Slavischen Sprachen.* Wien, 1886.—BALG. *A Comparative Glossary of the Gothic Language.* Mayville, Wisconsin, 1887–89.—*Thesaurus Linguae Latinae.* Leipzig, 1900. (B. E. S.)

**Didon, Henri** (1840–1900), French Dominican priest, was born at Touvet, Isère, on 17th March 1840. In his early life he was brought into relations with Lacordaire. In consequence, probably, of this he became a Dominican monk in 1862. He completed his theological studies at the Minerva Convent at Rome, and became a great admirer of the theology of Aquinas. The influence of Lacordaire was further shown in the zeal displayed by the young

preacher in favour of a reconciliation between philosophy and science. In 1871 his fame had so much grown that he was chosen to deliver the funeral oration over the murdered archbishop of Paris, Monseigneur Darboy. After this he delivered some discourses at the Church of St Jean de Beauvais in Paris on the relations between science and religion; but his utterances, especially on the question of divorce, were deemed suspicious by those in authority, and his intimacy with Claude Bernard the physiologist was disapproved. He was interdicted from preaching and sent into retirement at the Convent of Corbara in Corsica. After eighteen months he emerged, and travelled in Germany, publishing an interesting work upon that country, entitled *Les Allemands*, on his return to France. In 1890 he produced his best-known work, a Life of Jesus (*Jésus-Christ*), for which he had qualified himself by travel in the Holy Land. In the same year he became director of the College Albert-le-Grand (Albertus Magnus) at Arcueil, and himself founded three auxiliary institutions, École Lacordaire, École Laplace, and École St Dominique. He wrote, in addition, several works on educational questions, and augmented his fame as an eloquent preacher by discourses preached during Lent and Advent. He died in 1900. (J. J. L*.)

**Diedenhofen** (in French, *Thionville*), a fortified town of Germany, in Alsace-Lorraine, dist. Lorraine, on the Moselle, 22 miles north from Metz by rail, a railway junction of some consequence, with cultivation of wine, fruit, and vegetables, brewing, tanning, &c. It is an ancient Frank town (*Theudonevilla*, *Totonisvilla*), in which imperial diets were held in the 8th century; was captured by Condé in 1643 and fortified by Vauban; capitulated to the Prussians in 1870. Population (1885), 8111; (1900), 10,062.

**Dieppe,** chief town of arrondissement, department of Seine Inférieure, France, 35 miles north of Rouen, with terminal station on railway from Paris. The Palais de Justice is a recent erection. Lace, woollen goods, and ceramic wares are now important manufactures. The ivory carving has greatly declined in recent years, and instead of 300 in 1866 only about 40 workmen were employed in it in 1898. Efforts are being made, however, to give a fresh impetus to this industry. In 1900, 1894 vessels of 497,446 tons entered and cleared, of which Great Britain's share was 340,082 tons. Imports were valued (1899) at £5,248,000; exports at £6,732,000. The principal imports were textiles (chiefly silk), forming 50 per cent. The principal exports were textiles (silk, cotton, and woollen), amounting to 40 per cent., and hides and skins. During the summer months large quantities of fruit are sent to England. The total port traffic on the Canal de Bourgoyne amounted to 94,774 tons in 1899. The number of vessels engaged in the fisheries in 1898 was 95, with 471 men. A school of fisheries, similar to that which has already rendered good service at Sables d'Olonne, has been established at Dieppe. A new harbour railway station and a landing stage were opened in 1900, and an esplanade ¾ mile in length is in course of construction. The passenger traffic with England was represented in 1900 by 130,985 arrivals from and 139,143 departures to that country. The harbour, to which an improved approach is projected, comprises an outer and an inner port, with a total length of quayage 3772 feet. Depth at high tide in the outer port (ordinary spring) varies in different parts from 29 to 36 feet. There are four floating docks and a dry dock. The entrance channel, cut in the bed of the Arques, is 1950 feet long and 246 feet wide. Population (1881), 20,408; (1901), 21,798.

**Dietetics.**—The term dietetics is frequently applied to the science of the food and nutrition of man in health and disease. This article deals mainly with that part of the subject which has to do with the composition and nutritive values of foods and their adaptation to the use of people in health. The principal topics are:—1. Food and its functions. 2. Metabolism of matter and energy. 3. Digestibility and availability of food materials. 4. Fuel-value of food. 5. Composition of food materials. 6. Food consumption—studies of dietaries. 7. Hygienic economy of food. 8. Quantities of nutrients needed. 9. Pecuniary economy of food.

1. *Food and its Functions.*—Food is that which, taken into the body, builds tissue or yields energy. More specifically, food supplies the wants of the body in several ways:—(1) it forms the tissues and fluids of the body; (2) it repairs the waste of tissues; (3) it is stored in the body for future consumption; (4) it is consumed as fuel, its potential energy being transformed into heat or muscular energy or other forms of energy required by the body; and (5) in being consumed, it protects tissue or other food from consumption. The most healthful food is that which is best fitted to the needs of the user. To be adapted to his needs, the food must supply the different nutritive ingredients, or nutrients, in the kinds and proportions required by the body for building and repair and for supplying energy. It should also be in forms which the person can easily digest and which will "agree" with him. The cheapest food is that which furnishes the most nutriment at the least cost. The most economical food is that which is most healthful and cheapest. Ordinary food materials, such as meat, fish, eggs, potatoes, wheat, &c., consist of—*refuse*, *e.g.*, the bones of meat and fish, shells of shellfish, skin of potatoes, bran of wheat, &c.; *edible portion*, *e.g.*, the flesh of meat and fish, the white and yolk of eggs, wheat flour, &c. The edible portion consists of water and nutritive ingredients or nutrients.

The principal kinds of nutritive ingredients are *protein*, *fats*, *carbohydrates*, and *mineral matters*. The water, refuse (and salt of salted meat and fish), are here regarded as non-nutrients and, in comparing the values of different food materials for nourishment, are left out of account. The following are familiar examples of compounds of each of the four principal classes of nutrients:—

*Protein.*—The term protein is here used to include the nitrogenous nutrients of foods except the nitrogenous fat, namely, the proteids, *e.g.*, albumen (white of egg), casein (curd) of milk, myosin of muscle (lean meat), gluten of wheat, &c.; and the non-proteids, including the so-called extractives (*e.g.*, creatin) of meats and the amides (*e.g.*, asparagin), and allied compounds of vegetables and fruits.[1]

*Fats.*—Fat of meat; fat (butter) of milk, olive oil, oil of corn, wheat, &c. (Here are included the nitrogenized fats, as lecithin.)

*Carbohydrates.*—Sugars, starches, cellulose (woody fibre), &c.

*Mineral Matters.*—Phosphates, sulphates, and chlorides of potassium, sodium, calcium, &c.

Protein forms tissue (muscle, tendon, &c.) and fat, and serves as fuel. Fats form fatty tissue (not muscle, &c.) and serve as fuel. Carbohydrates are transformed into fat and serve as fuel. All these nutrients yield energy in the form of heat and muscular power. In being themselves burned to yield energy, the nutrients protect each other from being consumed. The protein and fats of body tissue

[1] Unfortunately the terms applied by different writers to these nitrogenous compounds are very conflicting. In accordance with a common usage, preference is here given to the word protein to cover all the nitrogenous compounds except the nitrogenous fats, though the word proteid is sometimes used in this signification.

are used like those of food. An important use of the carbohydrates and fats is to protect body tissue (muscle, &c.) from consumption. What compounds are especially concerned in the production of intellectual or nervous energy is not known. The idea that fish is especially rich in phosphorus and valuable as brain food has no foundation in observed fact.

Heat and muscular work represent forms of energy. The energy is developed as the food is consumed in the body, and is measured in the laboratory by means of an apparatus called the calorimeter. The unit commonly used is the calorie, the amount of heat which would raise the temperature of a kilogram of water 1 degree centigrade, or approximately 1 pound of water 4 degrees Fahrenheit. By heat of combustion is meant the amount of heat which a given substance yields upon combustion with oxygen outside the body. Thus a gram of cane-sugar yields 3·96 calories, and a gram of proteid, in the form of white of egg, 5·69 calories. By fuel-value is here meant the total energy which a given substance can yield the body; in other words, it is the heat of combustion of that part of the food which is capable of oxidation within the body.

2. *Metabolism of Matter and Energy.*—In so far as its material phenomena are concerned, life consists of transformations of matter and energy, to which the term metabolism is applied. The processes of metabolism are thus of two definite and closely allied kinds—the metabolism of matter, in which the changes are chemical, and that of energy, in which the changes are physical. To say that the chemical transformations in the body obey the law of the conservation of matter is simply to say that the body can neither create nor destroy matter—a principle long since demonstrated and universally accepted. It would seem that the metabolism of energy must in like manner obey the law of the conservation of energy, but owing to the great experimental difficulties the actual demonstration of this principle has been long delayed. For this demonstration it is necessary to prove that the income and expenditure of energy are equal. The body receives energy in the compounds of the food and drink. In the processes of nutrition the potential energy of these compounds is metabolized, and appears as kinetic energy in the heat given off from the body, and in the external muscular work performed, although a small amount remains unchanged, mostly in the unoxidized materials excreted by the kidneys, intestines, and otherwise. The minute quantities given off as electricity or light by some animals are here neglected. The apparatus and methods of experimenting lately devised make it possible to measure the energy of income in food and drink on the one hand, and that of expenditure in body heat, external work, and unoxidized excretory products on the other. The potential energy of income and expenditure is measured by the heat of combustion of food and excretory products as determined by burning with oxygen in the bomb calorimeter. The kinetic energy, which is found only in the expenditure, is measured by the respiration calorimeter—an apparatus in which the subject of the experiment (a man, for instance) remains for a number of days and nights under conditions which permit of comparison between the matter and energy taken in and given off. This involves weighings, measurements, and analyses of the food and drink, and of respiratory and other excretory products, and measurements of the heat given off by the body, and of the external mechanical work, allowance being made for the energy of the body material gained or lost during the experiment.

Partial measurements of income and expenditure of energy were published by Rubner[1] in 1894. The experiments were made with dogs without external muscular work. The income of energy was computed from the excretory products, while the outgoings in the form of heat (since no external muscular work was done) were measured directly. In the average of 8 experiments, which continued during 45 days, the two quantities agreed within 0·47 per cent., thus demonstrating, what the author desired to prove, that the heat given off from the body came solely from the oxidation of food within it. Results in accord with these were reported by Studenski[2] and by Laulanie in 1898.[3] Results of experiments with men have been lately published by Atwater, Rosa, and Benedict and associates,[4] who used a respiration calorimeter as above mentioned, and made detailed analyses and determinations of heats of combustion of food, drink, and excretory products, and measurements of heat given off by the body and the heat equivalent of the external muscular work done. In all, 30 experiments had been reported by November 1901, occupying from 2 to 4 days each, or a total of 93 days of experimenting. In some of these experiments the subject was at rest; in others he rode a stationary bicycle belted to a dynamo, so that the external muscular work was used to generate an electric current which was measured and afterwards transformed into heat within the calorimeter by passage through a resistance, the heat being measured with that given off by the body. The diet was generally not far from sufficient to maintain nitrogen and carbon equilibrium. In these experiments the energy actually measured, in the form of heat given off from the body and that from the external muscular work done in work experiments, accord on the average very closely with the estimated potential energy of the material oxidized in the body. It is to be observed, however, that the variations for individual days, and in the averages for the individual experiments as well, were considerable, sometimes amounting to 6 per cent., or even more. This is perhaps not strange in view of the physiological conditions of the experiments. In the average of all the experiments the measured energy of expenditure was 99·8 per cent. of the estimated energy of income; in other words, they agreed within two parts in one thousand. While these results do not absolutely prove the application of the law of the conservation of energy in the human body, they certainly approximate very closely to such demonstration. It is, of course, possible that energy may have been given off from the body in other forms than heat and external muscular work. Thus it is conceivable that intellectual activity may involve a transformation of physical energy, and that this energy may be eliminated in some form now unknown. But if the body did give off energy which was not measured in these experiments, the quantity must have been extremely small. It seems fair to infer from these results that the metabolism of energy in the body occurred in conformity with the law of the conservation of energy.

3. *Digestibility and Availability of Food.*—The value of a food for nutriment depends not only upon the kinds and amounts of nutrients which it contains, but also upon the proportions of these nutrients which the body can digest and make available, and upon the ease and convenience with which the materials are utilized. By digestion in the narrower sense is understood the changes, chiefly chemical, but partly physical, which the food undergoes in the alimentary canal in order to prepare it for absorption. By digestibility of food, as the term is popularly understood, several things are, or may be, meant. Some of these (as the ease with which a given food material is digested, the time required for the process, the influence of different methods of preparation, including cooking, and the influence of condiments) are so difficult of measurement, and others (as bodily conditions, and the question as to whether a given food agrees or disagrees with a given person) are so dependent upon the peculiarities of different individuals, as to make it impossible to lay down hard and fast rules. The term digestibility is also applied to the proportion of the several kinds of nutrients which the body can digest from different kinds of food materials. These proportions are best found by actual experiment in which

[4] Office of Experiment Stations, U.S. Department of Agriculture, Bulletin No. 63, "Description of a New Respiration Calorimeter," by W. O. Atwater and E. B. Rosa; and Bulletin No. 69, "Experiments on the Metabolism of Matter and Energy in the Human Body," by W. O. Atwater and F. G. Benedict.

people of different classes eat known amounts of different food materials, and the amounts digested are determined by weighings and analyses of the food and excreta. Suppose the diet to consist of bread and milk. The larger part of the nutrients will be digested, absorbed, taken into the circulation, and utilized. A small proportion, however, will pass through the intestines undigested, and along with this undigested residue there will also be excreted a certain amount of residuum, mainly from the digestive juices. That is to say, these two forms of residues, the undigested portions of the food and the metabolic products, are not oxidized, but are excreted together. To find what proportion of the diet is actually available to the body for the two great purposes of building of tissue and yielding of energy, we must take the total quantity of nutrients, and subtract the amounts given off unconsumed. Thus the handling of the bread and milk within the body, and getting it into condition to be metabolized in the system, involves the rejection by the intestines of a certain amount of material unavailable for the general purposes of nutrition. This brings out the difference between digestibility and availability. The former applies to the amounts actually digested in the alimentary canal, the latter to the amounts actually available for use. The difference is practically the amount used to digest the food and make it available.

This subject is comparatively new, and although experimental inquiries have been actively pushed since 1880, and especially since 1890, the results are still insufficient for exact statements regarding the availability of different kinds of food material. The following estimates[1] are based upon the results of nearly 300 experiments, made in Europe and in the United States, with persons, chiefly men, living upon different diets. The figures are subject to revision as data accumulate. While they are not to be taken as exact measures of the availability of every kind of food of each given class, they probably represent fairly well the average availability of these classes of food materials under ordinary circumstances.

*Coefficients of Availability and Fuel-Value of Nutrients.*

| Kind of Food. | Coefficients of Availability. | | | Fuel-Value per gram of Total Nutrients. | | |
|---|---|---|---|---|---|---|
| | Protein. | Fat. | Carbohydrates. | Protein. | Fat. | Carbohydrates. |
| | Per c. | Per c. | Per c. | Cals. | Cals. | Cals. |
| Meats and fish | 97 | 95 | 98 | 4·25 | 9·00 | 3·80 |
| Eggs | 97 | 95 | 98 | 4·35 | 9·00 | 3·80 |
| Dairy products | 97 | 95 | 98 | 4·25 | 8·80 | 3·80 |
| Animal food (of mixed diet) | 97 | 95 | 98 | 4·25 | 8·95 | 3·80 |
| Cereals | 85 | 90 | 98 | 3·70 | 8·35 | 4·10 |
| Legumes (dried) | 78 | 90 | 97 | 3·20 | 8·35 | 4·05 |
| Sugars | — | — | 98 | — | — | 3·85 |
| Starches | — | — | 98 | — | — | 4·10 |
| Vegetables | 83 | 90 | 95 | 2·90 | 8·35 | 4·00 |
| Fruits | 85 | 90 | 90 | 3·15 | 8·35 | 3·60 |
| Vegetable food (of mixed diet) | 85 | 90 | 97 | 3·55 | 8·35 | 4·00 |
| Total food (of mixed diet) | 92 | 95 | 97 | 4·00 | 8·90 | 4·00 |

4. *Fuel-Value of Food.*—The fuel-value of a particular food material depends on the proportions of available nutrients which can be oxidized in the body. It is commonly assumed that the available fats and carbohydrates are completely oxidized. Their fuel-value is the same as the heats of combustion of the available nutrients. The oxidation of the nitrogenous compounds,—proteids and non-proteids,—however, is not complete, considerable portions of the nitrogen being excreted in the kidneys in urea, creatinin, and other organic compounds. In determining the quantities of energy derived from the oxidation of the nitrogenous material in the body, therefore, allowance must be made for the energy lost to the body in these latter compounds. It will be seen that the term fuel-value is here used to represent the potential energy of the material actually oxidized, or capable of being oxidized, in the body. It thus represents the actually available energy, and might be called the physical fuel-value in distinction from the physiological fuel-value, which depends upon the ways the energy, made kinetic, is used by the body. This distinction corresponds to the one above made between the amounts of available nutrients and the extent to which they are actually utilized by the body.

The estimates of Rubner[2] commonly quoted for the fuel-value of the nutrients of mixed diet are as follow:—protein, 4·1; fats, 9·3; and carbohydrates, 4·1 calories per gram. These factors were, however, originally, intended to represent the average heat of combustion of the different nutrients in the ordinary mixed diet, allowance being made for the energy lost in the incomplete oxidation of the nitrogenous compounds of the urine. Later estimates have been made by Atwater and associates,[1] using data much more extensive than were available to Rubner, and including results of a considerable amount of experimenting in the United States. The factors for the different nutrients represent in each case the amount of energy which the body is capable of obtaining from one gram of the particular nutrient as it exists in the food as eaten in ordinary mixed diet.

*Estimates of Heats of Combustion and Fuel-Value of Nutrients in Ordinary Mixed Diet.*

| Nutrients. | Heat of Combustion. | Fuel-Value. |
|---|---|---|
| | Calories. | Calories. |
| One gram of protein | 5·65 | 4·0 |
| One gram of fats | 9·40 | 8·9 |
| One gram of carbohydrates | 4·10 | 4·0 |

Thus, averaging together the fats in ordinary mixed diet, one gram burned in the calorimeter would yield 9·40 calories of energy in the form of heat. Of this gram 95 per cent. is reckoned as available for oxidation in the body, and the part so oxidized would yield energy, in the form of heat, muscular work, &c., equivalent to $(9{\cdot}40 \times {\cdot}95 =)$ 8·9 calories. In like manner the heat of combustion of average protein is estimated at 5·65 calories per gram. Of this, 92 per cent. is estimated as available, and its potential energy would be $(5{\cdot}75 \times {\cdot}92 =)$ 5·2 calories. But part of this escapes oxidation, and is excreted by the kidneys. Allowing 1·2 calories for the potential energy of this portion, that actually oxidized will yield $(5{\cdot}2 - 1{\cdot}2 =)$ 4·0 calories, which is taken as the fuel-value of the protein. Similarly, 97 per cent. of the total energy of carbohydrates is assumed to be available for use in the body. Nutrients of the same class, but from different food materials, vary both in availability and in heat of combustion, and hence in fuel-value. The above estimates seem to represent the best averages available (1900), but are subject to revision.

5. *Composition of Food Materials.*—Different food materials vary widely in their proportions of nutrients, water, and refuse. In general, the animal foods have the most protein and fats, while the vegetable foods are rich in the carbohydrates—starch and sugar. The chief nutrient of lean meats and fish is protein. Cheese has a large quantity of protein because it contains the most of the proteids of the milk. Among the vegetable foods, beans and peas have a high proportion of protein. The proportion in oatmeal is also large. In wheat it is moderate, and in maize meal and rice it is rather small. The materials with the highest fuel-value are those with the most fat, because the fuel-value of the fat is, weight for weight, two and one-fourth times as great as that of either sugar, starch, or protein. Hence fat pork and butter lead the other materials in fuel-value. The fat meats in general

[1] Atwater and Bryant, Connecticut, Agricultural Experiment Station, 1899.

[2] *Ztschr. Biol.*, 21, 1885, p. 377.

stand high in this respect. So also do the grains, flour, and meal, as they have very little water and large quantities of carbohydrates. Potatoes are quite low in the list in respect to fuel-value as well as protein, principally because they are three-fourths water. For the same reason, milk, which is seven-eighths water, ranks low in respect to both protein and fuel-value.

Like food materials differ considerably in percentage composition. This is especially true of meats. Thus the leaner portions of beef from a fat animal may be nearly as fat as the fatter portions from a lean animal. From the analyses now available it would appear that American meats, especially beef and pork, are generally fatter than those produced upon the continent of Europe. English meat products seem to resemble American rather than continental European products in respect to fatness, although the published analyses are insufficient for definite comparison.

The foregoing table shows the average percentage composition of some of the more common food materials. The analyses are mostly of American products, since there are but few available analyses of English food materials, and these probably differ but little from the average of similar materials produced in the United States. The comparatively few available analyses of meats produced on the continent of Europe imply that they contain, as a rule, considerably less fat and more water, and often more protein, than American meats. The fuel-values per pound would consequently be smaller. The values for the leaner meats in the table would very likely represent more nearly the medium fat meats of the Continent, while values for medium fat meats in the table would probably represent fat meats of continental Europe. The figures for leaner parts of beef in the table are for such cuts or joints as the loin, shoulder, rump, and shank. The medium fat meats would include such portions as the rib, loin, and chuck, while the brisket, plate, and navel represent the fatter portions. The proportion of bone in meat as ordinarily purchased will vary from almost nothing in "shoulder clod" and "round" to as much as 40 or 50 per cent. in the shank. The composition of the materials in the table is shown for the edible portion free from refuse.

6. *Food Consumption—Studies of Dietaries.*—The actual food consumption of persons of different age, sex, and occupation is found by means of dietary studies. The general plan of such a study includes the determination of the amounts and composition of the food consumed by a given number of persons during a certain number of days, and the deduction of the quantities per person or per man per day. In dietary studies of families the number of meals for one man to which the total number of actual meals taken is equivalent is frequently estimated upon the basis of the potential energy of the relative amounts of food assumed to be eaten by men and women with different occupations, and by children of different ages, as compared with an adult man at moderately hard manual labour. These energy equivalents are somewhat arbitrary, and will require revision from time to time as data accumulate. Those used in the American dietary studies referred to below are[11]: A man at moderately active manual labour, 10; a man with sedentary occupation, or a woman with moderate work, or a boy between 14 and 16 years of age, 8; a girl between 14 and 16 years, 7; children between 10 and 13 years, 6; between 6 and 9 years, 5; between 2 and 5 years, 4; and under 2 years, 3. Until the last two decades comparatively few exact studies of actual food consumption of people of different age, sex, and occupation had been reported. More of these were from Germany than from any other country, although valuable work had been done in England, France, and elsewhere. Of late the activity of this kind of experimenting in Europe has increased, especially in Russia, Italy, and Sweden. Outside of Europe there has

[1] Meats, eggs, fish, and some vegetables and fruits contain more or less refuse in the form of bone, shell, skins, &c. Thus, on the average, the food materials enumerated above would contain about the following percentages of refuse: beef round 7, loin 13, side 17; veal leg 14, loin 17, side 23; mutton leg, loin, and side 16 to 19; pork loin 20; ham 14; chicken 26; turkey 23; eggs 11; fresh cod (bone, skin, &c.) 53; salt cod 25; and fresh mackerel 45 per cent. The proportion of refuse in vegetables and fruit may vary from 10 to 50 per cent., according to the way they are prepared for the table.

[2] Such as round, shoulder, rump, and shank.

[3] Such as rib, loin, and chuck.

[4] Such as brisket, plate, and flank.

[5] Typical of lean fish, such as haddock, bluefish, flounder, weakfish, bass, perch.

[6] Typical of fat fish, such as salmon, halibut, shad, &c.

[7] Typical of roots, such as parsnips, carrots, &c.

[8] Typical of leafy vegetables, such as cauliflower, lettuce, spinach, &c.

[9] Typical of such fruits as the pear, peach, apricot, &c.

[10] Typical of berries, such as raspberries, &c.

[11] Later experience has led to slight changes in the estimates for boys and girls, making: boys at 12, 7; 13–14, 8; 15–16, 9; and girls at 13–14, 7; 15–16, 8.

been considerable investigation in some Asiatic countries, notably Japan, but the most active inquiry during the past few years has been in the United States.

Not all the studies of dietaries are made with sufficient completeness to furnish accurate data. Those which are being made at the present time are probably more trustworthy than most of the older ones. The total number of studies of dietaries which have been reported is difficult to determine. The number which are sufficiently accurate to be included in statistical averages may perhaps be roughly estimated at 700 to 800, of which over 300 have been made within the past ten years in the United States, and more are rapidly accumulating. The number of persons in the individual studies has varied from 1 to 100 or more. The data thus accumulated may be regarded as the beginning of the study of the comparative nutrition of mankind, but are not yet sufficient to warrant the definite generalizations which are to be desired. The figures of the following table will serve as illustrations:—

*Quantities of Available Nutrients and Energy in Actual Daily Food Consumption of Persons in Different Circumstances.*

(*Quantities per Man per Day unless otherwise stated.*)

| | Number of Studies. | Number of Persons. | Protein. | Fat. | Carbo-hydrates | Fuel-Value |

[1] Quantities per person per day.

7. *Hygienic Economy of Food.*—For people in good health and with good digestion there are two important rules to be observed in the regulation of the diet. The first is to choose the things which "agree" with them, and to avoid those which they cannot digest and assimilate without harm. The second is to use such kinds and amounts of food as will supply the nutrients the body needs, and at the same time to avoid burdening it with superfluous material, to be disposed of at the cost of health and strength. There are people who, because of some peculiarity of the alimentary system, are debarred from using foods which for people in general are most wholesome and nutritious. Some persons cannot endure eggs, others suffer if they take milk, others have to avoid certain kinds of meat, and others experience great discomfort if they eat fruits. But these cases are exceptions. In the processes of cleavage which the compounds of the food undergo in the body, substances are often formed which may be in one way or another injurious. In this sense it is literally true that "what is one man's meat is another man's poison." But for the great majority of people in health proper combinations of the ordinary standard wholesome foods make a healthful diet. On the other hand, some foods have at times a great value over and above their use for nourishment. Fruits and garden vegetables often benefit people greatly, not as nutriment merely, for they may have very little of actual nutrients, but because of the vegetable acids or other substances which they contain, and which sometimes serve a most useful purpose.

8. *Quantities of Nutrients Needed.*—Various standards have been proposed by physiological chemists to represent the amounts of nutrients needed by people of different age, sex, and occupation for daily sustenance. The problem is this. How much protein, fats, and carbohydrates, or, more simply, what amounts of protein and energy, are required, under varying circumstances, to build and repair muscular and other nitrogenous materials, tissues, &c., and to supply the demand for internal and external muscular work, heat, or other forms of kinetic energy? Unfortunately, experimental data are still insufficient for entirely trustworthy averages. Two classes of data are employed for the estimates—dietary studies with considerable numbers of people, and metabolism experiments with individuals in which the income and expenditure of the body are studied by quantitative methods. The standards herewith are not to be considered as exact and final, but merely as tentative estimates of the amounts of nutrients and energy required. As the chief function of the fats and carbohydrates is to serve as fuel, their exact proportion in the diet is of less account than their total fuel-value. In the standards proposed by the present writer, therefore, no proportions of fats and carbohydrates are indicated, the

*Standards for Dietaries. Available Nutrients and Energy.*

|---|---|---|---|---|
| | Grams.[2] | Grams. | Grams. | Calories. |
| Man at hard work (Voit) | 133 | 95 | 437 | 3270 |
| Man at moderate work (Voit) | 109 | 53 | 485 | 2965 |
| Man with very hard muscular work (Atwater) | 161 | [3] | [3] | 5500 |
| Man with hard muscular work (Atwater) | 138 | [3] | [3] | 4150 |
| Man with moderately active muscular work (Atwater) | 115 | [3] | [3] | 3400 |
| Man with light muscular work (Atwater) | 103 | [3] | [3] | 3050 |
| Man at "sedentary" or woman with moderately active work (Atwater) | 92 | [3] | [3] | 2700 |
| Woman with light muscular work, or man without muscular exercise (Atwater) | 83 | [3] | [3] | 2450 |

[2] One ounce equals 28·35 grams.
[3] Fats and carbohydrates sufficient, with the protein, to furnish the required energy.

requirement being that the amounts of the two shall suffice, with the protein, to bring up the fuel-value of the food to the indicated amount. It is specially to be noted that the amounts are in terms of available rather than total nutrients and energy.

9. *Pecuniary Economy of Food.*—Statistics of income and cost of living in Great Britain, Germany, and the United States (Massachusetts)[1] show that from 50 to 60 per cent. or more of the income of wage-workers and other people in moderate circumstances is expended for food. This relatively large cost of food, and the important influence of diet upon health and strength, make a more widespread understanding of the subject very desirable. The maxim that "the best is the cheapest" does not apply to food. The best food, in the sense of that which is the finest in appearance and flavour, and which is sold at the highest price, is not generally the cheapest, nor is it always the most healthful or economical. The price of food is not regulated solely by its value for nutriment. Its agreeableness to the palate or to the buyer's fancy is a large factor in determining the current demand and market price. There is no more nutriment in an ounce of protein or fat from the tenderloin of beef than from the round or shoulder. The protein of animal food has, however, an advantage over that of vegetable foods. Animal foods, such as meats, fish, milk, and the like, gratify the palate as most vegetable foods do not, and, what is perhaps of still greater weight in regulating the demand and market price, they satisfy a real need by supplying protein and fats, which vegetable foods lack. In general, animal proteids are more easily and completely digested than vegetable. There is doubtless good ground for paying somewhat more for the same quantity of nutritive material in the animal food. For persons in good health the foods in which the nutrients are most expensive are like costly articles of adornment—people who can well afford them may be justified in buying them, but they are not economical.

[1] Report of Mass. Bureau of Labour, 1884.

The variations in the cost of the actual nutriment in different food materials may be illustrated by comparison of the amounts of nutrients obtained for a given sum in the materials as bought at ordinary market prices. This is done in the foregoing table, which shows the amounts of available nutrients, which one shilling would pay for, in different food materials at prices common in England.

(W. O. A.)

**Diez,** a town of Prussia, province of Hesse-Nassau, on the Lahn, 30 miles by rail east from Coblenz. It is overlooked by a former castle of the counts of Nassau-Dillenburg, now a prison. Near by is the cadet school of Castle Oranienstein, formerly a nunnery, with its beautiful gardens. It has saw-mills and tanneries and corn-mills. Population (1900), 4303.

**Differential Equations.**—Differential equations arise in the expression of the relations between quantities by the elimination of details, either unknown or regarded as unessential to the formulation of the relations in question. They give rise, therefore, to the two closely connected problems of determining what arrangement of details is consistent with them, and of developing, apart from these details, the general properties expressed by them. Very roughly, two methods of study can be distinguished, with the names Transformation-theories, Function-theories; the former concerned to reduce the algebraical relations to the fewest and simplest forms, eventually with the hope of obtaining explicit expressions of the dependent variables in terms of the independent variables; the latter concerned to determine what general descriptive relations among the quantities are involved by the differential equations, with as little

use of algebraical calculations as may be possible. Under the former heading we may, with the assumption of a few theorems belonging to the latter, arrange the theory of partial differential equations and Pfaff's problem, with their geometrical interpretations, as at present developed, and the applications of Lie's theory of transformation-groups to partial and to ordinary equations; under the latter, the study of linear differential equations in the manner initiated by Riemann, the applications of discontinuous groups, the theory of the singularities of integrals, and the study of potential equations with existence theorems arising therefrom. In order to be clear we shall enter into some detail in regard to partial differential equations of the first order, both those which are linear in any number of variables and those not linear in two independent variables, and also in regard to the function-theory of linear differential equations of the second order. Space renders impossible anything further than the briefest account of many other matters; in particular, the theories of partial equations of higher than the first order, the function-theory of the singularities of ordinary equations not linear and the applications to differential geometry, are taken account of only in the bibliography. It is believed that on the whole the article will be more useful to the reader than if explanations of method had been further curtailed to include more facts.

When we speak of a function without qualification, it is to be understood that in the immediate neighbourhood of a particular set $x_o, y_o, \cdot\cdot$ of values of the independent variables $x, y, \cdot\cdot\cdot$ of the function, at whatever point of the range of values for $x, y, \cdot\cdot\cdot$ under consideration $x_o, y_o, \cdot\cdot$ may be chosen, the function can be expressed as a series of positive integral powers of the differences $x-x_o$, $y-y_o, \cdot\cdot\cdot$, convergent when these are sufficiently small (see FUNCTION, ANALYTIC). Without this condition, which we express by saying that the function is developable about $x_o, y_o, \cdot\cdot$, many results provisionally stated in the transformation theories would be unmeaning or incorrect. If, then, we have a set of $k$ functions, $f_1 \cdot\cdot f_k$ of $n$ independent variables $x_1 \cdot\cdot x_n$, we say that they are independent when $n \geqq k$ and not every determinant of $k$ rows and columns vanishes of the matrix of $k$ rows and $n$ columns whose $r$-th row has the constituents $df_r/dx_1 \cdot\cdot df_r/dx_n$; the justification being in the theorem, which we assume, that if the determinant involving, for instance, the first $k$ columns be not zero for $x_1=x_1{}^o \cdot\cdot x_n=x_n{}^o$, and the functions be developable about this point, then from the equations $f_1=c_1 \cdot\cdot f_k=c_k$ we can express $x_1 \cdot\cdot x_k$ by convergent power series in the differences $x_{k+1}-x_k{}^o{}_{+1} \cdot\cdot x_n-x_n{}^o$, and so regard $x_1 \cdot\cdot x_k$ as functions of the remaining variables. This we often express by saying that the equations $f_1=c_1 \cdot\cdot f_k=c_k$ can be solved for $x_1 \cdot\cdot x_k$. The explanation is given as a type of explanation often understood in what follows.

***Ordinary equations of the first order.***

We may conveniently begin by stating the theorem: If each of the $n$ functions $\phi_1 \cdot\cdot \phi_n$ of the $(n+1)$ variables $x_1 \cdot\cdot x_n t$ be developable about the values $x_1{}^o \cdot\cdot x_n{}^o t^o$, the $n$ differential equations of the form $dx_i/dt=\phi_i(tx_1 \cdot\cdot x_n)$ are satisfied by convergent power series $x_r=x_r{}^o+(t-t^o)\mathrm{A}_{r1}+(t-t_o)^2 \mathrm{A}_{r2}+\cdot\cdot\cdot$ reducing respectively to $x_1{}^o \cdot\cdot x_n{}^o$ when $t=t^o$; and the only functions satisfying the equations and reducing respectively to $x_1{}^o \cdot\cdot x_n{}^o$ when $t=t^o$, are those determined by continuation of these series. If the result of solving these $n$ equations for $x_1{}^o \cdot\cdot x_n{}^o$ be written in the form $\omega_1(x_1 \cdot\cdot x_n t)=x_1{}^o \cdot\cdot \omega_n(x_1 \cdot\cdot x_n t)=x_n{}^o$, it is at once evident that the differential equation $df/dt+\phi_1 df/dx_1+\cdot\cdot\cdot+\phi_n df/dx_n=0$ possesses $n$ integrals, namely, the functions $\omega_1 \cdot\cdot \omega_n$, which are developable about the values $(x_1{}^o \cdot\cdot x_n{}^o t^o)$ and reduce respectively to $x_1 \cdot\cdot x_n$ when $t=t^o$. And in fact it has no other integrals so reducing. Thus this equation also possesses an unique integral reducing when $t=t^o$ to an arbitrary function $\psi(x_1 \cdot\cdot x_n)$, this integral being $\psi(\omega_1 \cdot\cdot \omega_n)$. Conversely, the existence of these *principal* integrals $\omega_1 \cdot\cdot \omega_n$ of the partial equation establishes the existence of the specified solutions of the ordinary equations $dx_i/dt=\phi_i$.

***Single homogeneous partial equation of the first order.***

The following sketch of the proof of the existence of these principal integrals for the case $n=2$ will show the character of more general investigations. Put $x$ for $x-x^o$, &c., and consider the equation $a(xyt)df/dx+b(xyt)df/dy=df/dt$, wherein the functions $a, b$ are developable about $x=0$, $y=0$, $t=0$; say $a(xyt)=a_o+ta_1+t^2a_2/2!+\cdot\cdot$, $b(xyt)=b_o+tb_1+t^2b_2/2!+\cdot\cdot$, so that $ad/dx+bd/dy=\delta_o+t\delta_1+\frac{1}{2}t^2\delta_2+\cdot\cdot$, where $\delta_r=a_r d/dx+b_r d/dy$. In order that $f=p_o+tp_1+t^2p_2/2!+\cdot\cdot$, wherein $p_o, p_1$ are power series in $x, y$, should satisfy the equation, it is necessary, as we find by equating like terms, that $p_1=\delta_o p_o$, $p_2=\delta_o p_1+\delta_1 p_o$, &c., and in general $p_{s+1}=\delta_o p_s+s_1\delta_1 p_{s-1}+s_2\delta_2 p_{s-2}+\cdot\cdot\cdot+\delta_s p_o$, where $s_r=(s!)/(r!)(s-r!)$. Now compare with the given equation another equation $\mathrm{A}(xyt)d\mathrm{F}/dx+\mathrm{B}(xyt)d\mathrm{F}/dy=d\mathrm{F}/dt$, wherein each coefficient in the expansion of either A or B is real and positive, and not less than the absolute value of the corresponding coefficient in the expansion of $a$ or $b$. In the second equation let us substitute a series $\mathrm{F}=\mathrm{P}_o+t\mathrm{P}_1+t^2\mathrm{P}_2/2!+\cdot\cdot$, wherein the coefficients in $\mathrm{P}_o$ are real and positive, and each not less than the absolute value of the corresponding coefficient in $p_o$; then putting $\Delta_r=\mathrm{A}_r d/dx+\mathrm{B}_r d/dy$, we obtain necessary equations of the same form as before, namely, $\mathrm{P}_1=\Delta_o\mathrm{P}_o$, $\mathrm{P}_2=\Delta_o\mathrm{P}_1+\Delta_1\mathrm{P}_o, \cdot\cdot\cdot$ and in general $\mathrm{P}_{s+1}=\Delta_o\mathrm{P}_s+s_1\Delta_1\mathrm{P}_{s-1}+\cdot\cdot+\Delta_s\mathrm{P}_o$.

***Proof of the existence of integrals.***

These give for every coefficient in $\mathrm{P}_{s+1}$ an integral aggregate with real positive coefficients of the coefficients in $\mathrm{P}_s, \mathrm{P}_{s-1}, \cdot\cdot\cdot, \mathrm{P}_o$ and the coefficients in A and B; and they are the same aggregates as would be given by the previously obtained equations for the corresponding coefficients in $p_{s+1}$ in terms of the coefficients in $p_s p_{s-1} \cdot\cdot p_o$ and the coefficients in $a$ and $b$. Hence as the coefficients in $\mathrm{P}_o$ and also in A, B are real and positive, it follows that the values obtained in succession for the coefficients in $\mathrm{P}_1$, $\mathrm{P}_2, \cdot\cdot$ are real and positive; and further, taking account of the fact that the absolute value of a sum of terms is not greater than the sum of the absolute values of the terms, it follows, for each value of $s$, that every coefficient in $p_{s+1}$ is, in absolute value, not greater than the corresponding coefficient in $\mathrm{P}_{s+1}$. Thus if the series for F be convergent, the series for $f$ will also be; and we are thus reduced to (1), specifying functions A, B with real positive coefficients, each in absolute value not less than the corresponding coefficient in $a, b$; (2) proving that the equation $\mathrm{A}d\mathrm{F}/dx+\mathrm{B}d\mathrm{F}/dy=d\mathrm{F}/dt$ possesses an integral $\mathrm{P}_o+t\mathrm{P}_1+t^2\mathrm{P}_2/2!+\cdot\cdot$ in which the coefficients in $\mathrm{P}_o$ are real and positive, and each not less than the absolute value of the corresponding coefficient in $p_o$. If $a, b$ be developable for $x, y$ both in absolute value less than $r$ and for $t$ less in absolute value than R, and for such values $a, b$ be both less in absolute value than the real positive constant M, it is not difficult to verify that we may take $\mathrm{A}=\mathrm{B}=\mathrm{M}\left(1-\frac{x+y}{r}\right)^{-1}\left(1-\frac{t}{\mathrm{R}}\right)^{-1}$, and obtain

$$\mathrm{F}=r-(r-x-y)\left[1-\frac{4\mathrm{MR}}{r}\left(1-\frac{x+y}{r}\right)^{-2}\log\left(1-\frac{t}{\mathrm{R}}\right)^{-1}\right]^{\frac{1}{2}},$$

and that this solves the problem when $x, y, t$ are sufficiently small for the two cases $p_o=x$, $p_o=y$. One obvious application of the general theorem is to the proof of the existence of an integral of an ordinary linear differential equation given by the $n$ equations $dy/dx=y_1$, $dy_1/dx=y_2, \cdot\cdot$, $dy_{n-1}/dx=p-p_1y_{n-1}-\cdot\cdot\cdot-p_ny$; but in fact any simultaneous system of ordinary equations is reducible to a system of the form $dx_i/dt=\phi_i(tx_1 \cdot\cdot x_n)$.

***Simultaneous linear partial equations.***

Suppose we have $k$ homogeneous linear partial equations of the first order in $n$ independent variables, the general equation being $a_{\sigma 1}df/dx_1+\cdot\cdot+a_{\sigma n}df/dx_n=0$, where $\sigma=1 \cdot\cdot k$, and that we desire to know whether the equations have common solutions, and if so, how many. It is to be understood that the equations are linearly independent, which implies that $k \leqq n$ and not every determinant of $k$ rows and columns is identically zero in the matrix in which the $i$-th element of the $\sigma$-th row is $a_{\sigma i}(i=1 \cdot\cdot n,\ \sigma=1 \cdot\cdot k)$. Denoting the left side of the $\sigma$-th equation by $\mathrm{P}_\sigma f$, it is clear that every common solution of the two equations $\mathrm{P}_\sigma f=0$, $\mathrm{P}_\rho f=0$ is also a solution of the equation $\mathrm{P}_\rho(\mathrm{P}_\sigma f)-\mathrm{P}_\sigma(\mathrm{P}_\rho f)=0$. We immediately find, however, that this is also a linear equation, namely, $\Sigma \mathrm{H}_i df/dx_i=0$ where $\mathrm{H}_i=\mathrm{P}_\rho a_{\sigma i}-\mathrm{P}_\sigma a_{\rho i}$, and if it be not already contained among the given equations, or be linearly deducible from them, it may be added to them, as not introducing any additional limitation of the possibility of their having common solutions. Proceeding thus with every pair of the original equations, and then with every pair of the possibly augmented system so obtained, and so on continually, we shall arrive at a system of equations, linearly independent of each other and therefore not more than $n$ in number, such that the combination, in the way described, of every pair of them, leads to an equation which is linearly deducible from them. If the number of this so-called *complete system* is $n$, the equations give $df/dx_1=0 \cdot\cdot df/dx_n=0$, leading to the nugatory result $f=$ a constant. Suppose, then, the number of this system to be $r < n$; suppose, further, that from the matrix of the coefficients

a determinant of $r$ rows and columns not vanishing identically is that formed by the coefficients of the differential coefficients of $f$ in regard to $x_1 \cdots x_r$; also that the coefficients are all developable about the values $x_1=x_1^o \cdots x_n=x_n^o$, and that for these values the determinant just spoken of is not zero. Then the main theorem is that the complete system of $r$ equations, and therefore the originally given set of $k$ equations, have in common $n-r$ solutions, say $\omega_{r+1} \cdots \omega_n$, which reduce respectively to $x_{r+1} \cdots x_n$ when in them for $x_1 \cdots x_r$ are respectively put $x_1^o \cdots x_r^o$; so that also the equations have in common a solution reducing when $x_1=x_1^o \cdots x_r=x_r^o$ to an arbitrary function $\psi(x_{r+1} \cdots x_n)$ which is developable about $x_r^o{}_{+1} \cdots x_n^o$, namely, this common solution is $\psi(\omega_{r+1} \cdots \omega_n)$. It is seen at once that this result is a generalization of the theorem for $r=1$, and its proof is conveniently given by induction from that case. It can be verified without difficulty (1) that if from the $r$ equations of the complete system we form $r$ independent linear aggregates, with coefficients not necessarily constants, the new system is also a complete system; (2) that if in place of the independent variables $x_1 \cdots x_n$ we introduce any other variables which are independent functions of the former, the new equations also form a complete system. It is convenient, then, from the complete system of $r$ equations to form $r$ new equations by solving separately for $df/dx_1, \cdots, df/dx_r$; suppose the general equation of the new system to be $Q_\sigma f=df/dx_\sigma+c_{\sigma,r+1}df/dx_{r+1}+\cdots+c_{\sigma n}df/dx_n=0(\sigma=1\cdots r)$. Then it is easily obvious that the equation $Q_\rho Q_\sigma f - Q_\sigma Q_\rho f=0$ contains only the differential coefficients of $f$ in regard to $x_{r+1} \cdots x_n$; as it is at most a linear function of $Q_1 f, \cdots, Q_r f$, it must be identically zero. So reduced the system is called a *Jacobian system*. Of this system $Q_1 f=0$ has $n-1$ principal solutions reducing respectively to $x_2 \cdots x_n$ when $x_1=x_1^o$, and its form shows that of these the first $r-1$ are exactly $x_2 \cdots x_r$. Let these $n-1$ functions together with $x_1$ be introduced as $n$ new independent variables in all the $r$ equations. Since the first equation is satisfied by $n-1$ of the new independent variables, it will contain no differential coefficients in regard to them, and will reduce therefore simply to $df/dx_1=0$, expressing that any common solution of the $r$ equations is a function only of the $n-1$ remaining variables. Thereby the investigation of the common solutions is reduced to the same problem for $r-1$ equations in $n-1$ variables. Proceeding thus, we reach at length one equation in $n-r+1$ variables, from which, by retracing the analysis, the proposition stated is seen to follow.

***Complete systems of linear partial equations.***

***Jacobian systems.***

The analogy with the case of one equation is, however, still closer. With the coefficients $c_{\sigma,j}$ of the equations $Q_\sigma f=0$ in transposed array $(\sigma=1\cdots r,\ j=r+1\cdots n)$ we can put down the $(n\text{-}r)$ equations, $dx_j=c_{1j}dx_1+\cdots+c_{rj}dx_r$, equivalent to the $r(n-r)$ equations $dx_j/dx_\sigma=c_{\sigma j}$. That consistent with them we may be able to regard $x_{r+1} \cdots x_n$ as functions of $x_1 \cdots x_r$, these being regarded as independent variables, it is clearly necessary that when we differentiate $c_{\sigma j}$ in regard to $x_\rho$ on this hypothesis the result should be the same as when we differentiate $c_{\rho j}$ in regard to $x_\sigma$ on this hypothesis. The differential coefficient of a function $f$ of $x_1 \cdots x_n$ on this hypothesis, in regard to $x_\rho$, is, however, $df/dx_\rho+c_{\rho,r+1}df/dx_{r+1}+\cdots+c_{\rho n}df/dx_n$, namely, is $Q_\rho f$. Thus the consistence of the $n-r$ total equations requires the conditions $Q_\rho c_{\sigma j}-Q_\sigma c_{\rho j}=0$, which are, however, verified in virtue of $Q_\rho(Q_\sigma f)-Q_\sigma(Q_\rho f)=0$. And it can in fact be easily verified that if $\omega_{r+1} \cdots \omega_n$ be the principal solutions of the Jacobian system, $Q_\sigma f=0$, reducing respectively to $x_{r+1} \cdots x_n$ when $x_1=x_1^o \cdots x_r=x_r^o$, and the equations $\omega_{r+1}=x_r^o{}_{+1} \cdots \omega_n=x_n^o$ be solved for $x_{r+1} \cdots x_n$ to give $x_j=\psi_j(x_1 \cdots x_r,\ x_r^o{}_{+1} \cdots x_n^o)$, these values solve the total equations and reduce respectively to $x_r^o{}_{+1} \cdots x_n^o$ when $x_1=x_1^o \cdots x_r=x_r^o$. And the total equations have no other solutions with these initial values. Conversely, the existence of these solutions of the total equations can be deduced *à priori* and the theory of the Jacobian system based upon them. The theory of such total equations, in general, finds its natural place under the heading *Pfaffian Expressions*, below.

***System of total differential equations.***

A practical method of reducing the solution of the $r$ equations of a Jacobian system to that of a single equation in $n-r+1$ variables may be explained in connexion with a geometrical interpretation which will perhaps be clearer in a particular case, say $n=3$, $r=2$. There is then only one total equation, say $dz=adx+bdy$; if we do not take account of the condition of integrability, which is here $da/dy+bda/dz=db/dx+adb/dz$, this equation may be regarded as defining through an arbitrary point $x_oy_oz_o$ of three-dimensional space (about which $a$, $b$ are developable) a plane, namely, $z-z_o=a_o(x-x_o)+b_o(y-y_o)$, and therefore, through this arbitrary point $\infty^2$ directions, namely, all those in the plane. If now there be a surface $z=\psi(xy)$, satisfying $dz=adx+bdy$ and passing through $x_oy_oz_o$, this plane will touch the surface, and the operations of passing along the surface from $(x_oy_oz_o)$ to $(x_o+dx_o,\ y_o,\ z_o+dz_o)$ and then to $(x_o+dx_o,\ y_o+dy_o,\ z_o+d^1z_o)$, ought to lead to the same value of $d^1z_o$ as do the operations of passing along the surface from $(x_oy_oz_o)$ to $(x_o,\ y_o+dy_o,\ z_o+\delta z_o)$, and then to $(x_o+dx_o,\ y_o+dy_o,\ z_o+\delta^1z_o)$, namely, $\delta^1z_o$ ought to be equal to $d^1z_o$. But we find $d^1z_o=a_odx_o+b(x_o+dx_o,\ y_o,\ z_o+a_odx_o)dy_o=a_odx_o+b_ody_o+dx_ody_o\left(\frac{db}{dx_o}+a_o\frac{db}{dz_o}\right)$, and so at once reach the condition of integrability. If now we put $x=x_o+t$, $y=y_o+mt$, and regard $m$ as constant, we shall in fact be considering the section of the surface by a fixed plane $y-y_o=m(x-x_o)$; along this section $dz=dt(a+bm)$; if we then integrate the equation $dz/dt=a+bm$, where $a$, $b$ are expressed as functions of $m$ and $t$, with $m$ kept constant, finding the solution which reduces to $z_o$ for $t=0$, and in the result again replace $m$ by $(y-y_o)/(x-x_o)$, we shall have the surface in question. In the general case the equations $dx_j=c_{1j}dx_1+\cdots+c_{rj}dx_r$ similarly determine through an arbitrary point $x_1^o \cdots x_n^o$ a planar manifold of $r$ dimensions in space of $n$ dimensions, and when the conditions of integrability are satisfied, every direction in this manifold through this point is tangent to the manifold of $r$ dimensions, expressed by $\omega_{r+1}=x_r^o{}_{+1} \cdots \omega_n=x_n^o$, which satisfies the equations and passes through this point. If we put $x_1-x_1^o=t$, $x_2-x_2^o=m_2t$, $\cdots$, $x_r-x_r^o=m_rt$, and regard $m_2 \cdots m_r$ as fixed, the $(n-r)$ total equations take the form $dx_j/dt=c_{1j}+m_2c_{2j}+\cdots+m_rc_{rj}$, and their integration is equivalent to that of the single partial equation $df/dt+\sum_{j=r+1}^{n}(c_{1j}+m_2c_{2j}+\cdots+m_rc_{rj})df/dx_j=0$ in the $n-r+1$ variables $t$, $x_{r+1} \cdots x_n$. Determining the solutions $\Omega_{r+1} \cdots \Omega_n$ which reduce to respectively $x_{r+1} \cdots x_n$ when $t=0$, and putting therein $t=x_1-x_1^o$, $m_2=(x_2-x_2^o)/(x_1-x_1^o)$, $\cdots$, $m_r=(x_r-x_r^o)/(x_1-x_1^o)$, we obtain the solutions of the original system of partial equations previously denoted by $\omega_{r+1} \cdots \omega_n$. It is to be remarked, however, that the presence of the fixed parameters $m_2 \cdots m_r$ in the single integration may frequently render it more difficult than if they were assigned numerical quantities.

***Geometrical interpretation and solution.***

***Mayer's method of integration.***

We have above considered the integration of an equation $dz=adx+bdy$ on the hypothesis that the condition $da/dy+bda/dz=db/dx+adb/dz$. It is natural to inquire what relations among $x$, $y$, $z$, if any, are implied by, or are consistent with, a differential relation $adx+bdy+cdz=o$, when $a$, $b$, $c$ are unrestricted functions of $x$, $y$, $z$. This problem leads to the consideration of the so-called Pfaffian *Expression* $adx+bdy+cdz$; it can be shown (1) if each of the quantities $db/dz-dc/dy$, $dc/dx-da/dz$, $da/dy-db/dx$, which we shall denote respectively by $u_{23}$, $u_{31}$, $u_{12}$, be identically zero, the expression is the differential of a function of $x$, $y$, $z$, equal to $dt$ say; (2) that if the quantity $au_{23}+bu_{31}+cu_{12}$ is identically zero, the expression is of the form $udt$, that is can be made a perfect differential by multiplication by the factor $\frac{1}{u}$; (3) that in general the expression is of the form $dt+u_1dt_1$. Consider the matrix of four rows and three columns, in which the elements of the first row are $a$, $b$, $c$, and the elements of the $(r+1)$-th row, for $r=1$, 2, 3, are the quantities $u_{r1}$, $u_{r2}$, $u_{r3}$, where $u_{11}=u_{22}=u_{33}=0$. Then it is easily seen that the cases (1), (2), (3) above correspond respectively to the cases when (1) every determinant of this matrix of two rows and columns is zero, (2) every determinant of three rows and columns is zero, (3) when no condition is assumed. This result can be generalized as follows: if $a_1 \cdots a_n$ be any functions of $x_1 \cdots x_n$, the so-called Pfaffian expression $a_1dx_1+\cdots+a_ndx_n$ can be reduced to one or other of the two forms $u_1dt_1+\cdots+u_kdt_k$, $dt+u_1dt_1+\cdots+u_{k-1}dt_{k-1}$, wherein $t$, $u_1, \cdots, t_1, \cdots$ are independent functions of $x_1 \cdots x_n$, and $k$ is such that in these two cases respectively $2k$ or $2k-1$ is the rank of a certain matrix of $n+1$ rows and $n$ columns, that is, the greatest number of rows and columns in a non-vanishing determinant of the matrix; the matrix is that whose first row is constituted by the quantities $a_1 \cdots a_n$, whose $s$-th element in the $(r+1)$-th row is the quantity $da_r/dx_s-da_s/dx_r$. The proof of such a reduced form can be obtained from the two results: (1) If $t$ be any given function of the $2m$ independent variables $u_1 \cdots u_mt_1 \cdots t_m$, the expression $dt+u_1dt_1+\cdots+u_mdt_m$ can be put into the form $u'_1dt'_1+\cdots+u'_mdt'_m$. (2) If the quantities $u_1 \cdots u_mt_1 \cdots t_m$ be connected by a relation, the expression $u_1dt_1+\cdots+u_mdt_m$ can be put into the form $dt'+u'_1dt'_1+\cdots+u'_{m-1}dt'_{m-1}$; and if the relation connecting $u_1 \cdots u_mt_1 \cdots t_m$ be homogeneous in $u_1 \cdots u_m$, then $t'$ can be taken to be zero. These two results are deductions from the theory of *contact transformations* (see below), and their demonstration requires, beside elementary algebraical considerations, only the theory of complete systems of linear homogeneous partial differential equations of the first order. When the existence of the reduced form of the Pfaffian expression containing only independent quantities is thus once assured, the identification of the number $k$ with that defined by the specified matrix may, with some difficulty, be made *à posteriori*.

***Pfaffian Expressions.***

In all cases of a single Pfaffian equation we are thus led to consider what is implied by a relation $dt-u_1dt_1-\cdots-u_mdt_m=0$, in which $t, u_1 \cdots u_mt_1 \cdots t_m$ are, except for this equation, independent variables. This is to be satisfied in virtue of one or several relations connecting the variables; these must involve relations con-

necting $t, t_1 \cdots t_m$ only, and in one of these at least $t$ must actually enter. We can then suppose that in one actual system of relations in virtue of which the Pfaffian equation is satisfied, all the relations connecting $t, t_1 \cdots t_m$ only are given by $t=\psi(t_{s+1} \cdots t_m)$, $t_1=\psi_1(t_{s+1} \cdots t_m) \cdots t_s=\psi_s(t_{s+1} \cdots t_m)$; so that the equation $d\psi - u_1 d\psi_1 - \cdots - u_s d\psi_s - u_{s+1}dt_{s+1} - \cdots - u_m dt_m = 0$ is identically true in regard to $u_1 \cdots u_m$ $t_{s+1} \cdots t_m$; equating to zero the coefficients of the differentials of these variables, we thus obtain $m$-$s$ relations of the form $d\psi/dt_j - u_1 d\psi_1/dt_j - \cdots - u_s d\psi_s/dt_j - u_j = 0$; these $m$-$s$ relations, with the previous $s+1$ relations, constitute a set of $m+1$ relations connecting the $2m+1$ variables in virtue of which the Pfaffian equation is satisfied independently of the form of the functions $\psi, \psi_1 \cdots \psi_s$. There is clearly such a set for each of the values $s=0$, $s=1, \cdots$, $s=m-1$, $m$. And for any value of $s$ there may exist relations additional to the specified $m+1$ relations, provided they do not involve any relation connecting $t, t_1 \cdots t_m$ only, and are consistent with the $m$-$s$ relations connecting $u_1 \cdots u_m$. It is now evident that, essentially, the integration of a Pfaffian equation $a_1 dx_1 + \cdots + a_n dx_n = 0$, wherein $a_1 \cdots a_n$ are functions of $x_1 \cdots x_n$, is effected by the processes necessary to bring it to its reduced form, involving only independent variables. And it is easy to see that if we suppose this reduction to be carried out in all possible ways, there is no need to distinguish the classes of integrals corresponding to the various values of $s$; for it can be verified without difficulty that by putting $t'=t-u_1t_1-\cdots-u_st_s$, $t'_1=u_1, \cdots, t'_s=u_s$, $u'_1=-t_1, \cdots$, $u'_s=-t_s$, $t'_{s+1}=t_{s+1} \cdots t'_m=t_m$, $u'_{s+1}=u_{s+1} \cdots u'_m=u_m$, the reduced equation becomes changed to $dt'-u'_1dt'_1-\cdots-u'_mdt'_m=0$, and the general relations changed to $t'=\psi(t'_{s+1} \cdots t'_m)-t'_1\psi_1(t'_{s+1} \cdots t'_m) - \cdots - t'_s\psi_s(t'_{s+1} \cdots t'_m), =\phi$, say, together with $u'_1=d\phi/dt'_1, \cdots$, $u'_m=d\phi/dt'_m$, which contain only one relation connecting the variables $t'\, t'_1 \cdots t'_m$ only.

***Single linear Pfaffian equation.***

This method for a single Pfaffian equation can, strictly speaking, be generalized to a simultaneous system of ($n$-$r$) Pfaffian equations $dx_j = c_{1j}dx_1 + \cdots + c_{rj}dx_r$ only in the case already treated, when this system is satisfied by regarding $x_{r+1} \cdots x_n$ as suitable functions of the independent variables $x_1 \cdots x_r$; in that case the integral manifolds are of $r$ dimensions. When these are non-existent, there may be integral manifolds of higher dimensions; for if $d\phi=\phi_1dx_1+\cdots+\phi_rdx_r+\phi_{r+1}(c_{1r+1}dx_1+\cdots+c_{rr+1}dx_r)+\phi_{r+2}(\quad)+\cdots$ be identically zero, then $\phi_\sigma+c_{\sigma r+1}\phi_{r+1}+\cdots+c_{\sigma n}\phi_n=0$, or $\phi$ satisfies the $r$ partial differential equations previously associated with the total equations; when these are not a complete system, but included in a complete system of $r+\mu$ equations, having therefore $n-r-\mu$ independent integrals, the total equations are satisfied over a manifold of $r+\mu$ dimensions. See E. v. Weber, *Math. Annal.* lv. (1901), p. 386.

***Simultaneous Pfaffian equations.***

It seems desirable to add here certain results, largely of algebraic character, which naturally arise in connexion with the theory of contact transformations. For any two functions of the $2n$ independent variables $x_1 \cdots x_np_1 \cdots p_n$ we denote by $(\phi\psi)$ the sum of the $n$ terms such as $\dfrac{d\phi}{dp_i}\dfrac{d\psi}{dx_i}-\dfrac{d\psi}{dp_i}\dfrac{d\phi}{dx_i}$. For two functions of the $(2n+1)$ independent variables $zx_1 \cdots x_np_1 \cdots p_n$ we denote by $[\phi\psi]$ the sum of the $n$ terms such as $\dfrac{d\phi}{dp_i}\left(\dfrac{d\psi}{dx_i}+p_i\dfrac{d\psi}{dz}\right)-\dfrac{d\psi}{dp_i}\left(\dfrac{d\phi}{dx_i}+p_i\dfrac{d\phi}{dz}\right)$. It can at once be verified that for any three functions $[f[\phi\psi]]+[\phi[\psi f]]+[\psi[f\phi]]=\dfrac{df}{dz}[\phi\psi]+\dfrac{d\phi}{dz}[\psi f]+\dfrac{d\psi}{dz}[f\phi]$, which when $f, \phi, \psi$ do not contain $z$ becomes the identity $(f(\phi\psi))+(\phi(\psi f))+(\psi(f\phi))=0$. Then if $X_1 \cdots X_nP_1 \cdots P_n$ be such functions of $x_1 \cdots x_np_1 \cdots p_n$ that $P_1dX_1+\cdots+P_ndX_n$ is identically equal to $p_1dx_1+\cdots+p_ndx_n$, it can be shown by elementary algebra, after equating coefficients of independent differentials, (1) that the functions $X_1 \cdots P_n$ are independent functions of the $2n$ variables $x_1 \cdots p_n$, so that the equations $x'_i=X_i$, $p'_i=P_i$ can be solved for $x_1 \cdots x_np_1 \cdots p_n$, and represent therefore a transformation, which we call a homogeneous contact transformation; (2) that the $X_1 \cdots X_n$ are homogeneous functions of $p_1 \cdots p_n$ of zero dimensions, the $P_1 \cdots P_n$ are homogeneous functions of $p_1 \cdots p_n$ of dimension one, and the $\frac{1}{2}n(n-1)$ relations $(X_iX_j)=0$ are verified. So also are the $n^2$ relations $(P_iX_i)=1$, $(P_iX_j)=0$, $(P_iP_j)=0$. Conversely, if $X_1 \cdots X_n$ be independent functions, each homogeneous of zero dimension in $p_1 \cdots p_n$, satisfying the $\frac{1}{2}n(n-1)$ relations $(X_iX_j)=0$, then $P_1 \cdots P_n$ can be uniquely determined, by solving linear algebraic equations, such that $P_1dX_1+\cdots+P_ndX_n=p_1dx_1+\cdots+p_ndx_n$. If now we put $n+1$ for $n$, put $z$ for $x_{n+1}$, Z for $X_{n+1}$, $Q_i$ for $-P_i/P_{n+1}$, for $i=1 \cdots n$, put $q_i$ for $-p_i/p_{n+1}$ and $\sigma$ for $q_{n+1}/Q_{n+1}$, and then finally write $P_1 \cdots P_np_1 \cdots p_n$ for $Q_1 \cdots Q_nq_1 \cdots q_n$, we obtain the following results: If $ZX_1 \cdots X_nP_1 \cdots P_n$ be functions of $zx_1 \cdots x_np_1 \cdots p_n$, such that the expression $dZ-P_1dX_1-\cdots-P_ndX_n$ is identically equal to $\sigma(dz-p_1dx_1-\cdots-p_ndx_n)$, and $\sigma$ not zero, then (1) the functions $ZX_1 \cdots X_nP_1 \cdots P_n$ are independent functions of $zx_1 \cdots x_np_1 \cdots p_n$, so that the equations $z'=Z$, $x'_i=X_i$, $p'_i=P_i$ can be solved for $zx_1 \cdots x_np_1 \cdots p_n$, and determine a transformation which we call a (non-homogeneous) contact transformation; (2) the $ZX_1 \cdots X_n$ verify the $\frac{1}{2}n(n+1)$ identities $[ZX_i]=0$, $[X_iX_j]=0$. And the further identities $[P_iX_i]=\sigma$, $[P_iX_j]=0$, $[P_iZ]=\sigma P_i$, $[P_iP_j]=0$, $[Z\sigma]=\sigma\dfrac{dZ}{dz}-\sigma^2$, $[X_i\sigma]=\sigma\dfrac{dX_i}{dz}$, $[P_i\sigma]=\sigma\dfrac{dP_i}{dz}$ are also verified. Conversely, if $ZX_1 \cdots X_n$ be independent functions satisfying the identities $[ZX_i]=0$, $[X_iX_j]=0$, then $\sigma$, other than zero, and $P_1 \cdots P_n$ can be uniquely determined, by solution of algebraic equations, such that $dZ-P_1dX_1-\cdots-P_ndX_n=\sigma(dz-p_1dx_1-\cdots-p_ndx_n)$. Finally, there is a particular case of great importance arising when $\sigma=1$, which gives the results: (1) If $UX_1 \cdots X_nP_1 \cdots P_n$ be $2n+1$ functions of the $2n$ independent variables $x_1 \cdots x_np_1 \cdots p_n$, satisfying the identity $dU+P_1dX_1+\cdots+P_ndX_n=p_1dx_1+\cdots+p_ndx_n$, then the $2n$ functions $P_1 \cdots P_nX_1 \cdots X_n$ are independent, and we have $(X_iX_j)=0$, $(X_iU)=\delta X_i$, $(P_iX_i)=1$, $(P_iX_j)=0$, $(P_iP_j)=0$, $(P_iU)+P_i=\delta P_i$, where $\delta$ denotes the operator $p_1d/dp_1+\cdots+p_nd/dp_n$; (2) If $X_1 \cdots X_n$ be independent functions of $x_1 \cdots x_np_1 \cdots p_n$, such that $(X_iX_j)=0$, then U can be found by a quadrature, such that $(X_iU)=\delta X_i$; and when $X_i \cdots X_n$, U satisfy these $\frac{1}{2}n(n+1)$ conditions, then $P_1 \cdots P_n$ can be found, by solution of linear algebraic equations, to render true the identity $dU+P_1dX_1+\cdots+P_ndX_n=p_1dx_1+\cdots+p_ndx_n$; (3) Functions $X_1 \cdots X_nP_1 \cdots P_n$ can be found to satisfy this differential identity when U is an arbitrary given function of $x_1 \cdots x_np_1 \cdots p_n$; but this requires integrations. In order to see what integrations, it is only necessary to verify the statement that if U be an arbitrary given function of $x_1 \cdots x_np_1 \cdots p_n$, and, for $r<n$, $X_1 \cdots X_r$ be independent functions of these variables, such that $(X_\sigma U)=\delta X_\sigma$, $(X_\rho X_\sigma)=0$, for $\rho, \sigma=1 \cdots r$, then the $r+1$ homogeneous linear partial differential equations of the first order $(Uf)+\delta f=0$, $(X_\rho f)=0$, form a complete system. It will be seen that the assumptions above made for the reduction of Pfaffian expressions follow from the results here enunciated for contact transformations.

***Contact transformations.***

We pass on now to consider the solution of any partial differential equation of the first order; we attempt to explain certain ideas relatively to a single equation with any number of independent variables (in particular, an ordinary equation of the first order with one independent variable) by speaking of a single equation with two independent variables $x$, $y$, and one dependent variable $z$. It will be seen that we are naturally led to consider systems of such simultaneous equations, of which we give some account below. The central discovery of the transformation theory of the solution of an equation $F(x, y, z, dz/dx, dz/dy)=0$ is that its solution can be reduced to the solution of partial equations which are *linear*. For this, however, we must regard $dz/dx$, $dz/dy$, during the process of integration, not as the differential coefficients of a function $z$ in regard to $x$ and $y$, but as variables independent of $x, y, z$, the too great indefiniteness that might thus appear to be introduced being provided for in another way. We notice, in fact, that if $z=\psi(x,y)$ be a solution of the differential equation, then $dz=dx\,d\psi/dx+dy\,d\psi/dy$; thus if we denote the equation by $F(xyzpq)=0$, and prescribe the condition $dz=pdx+qdy$ for every solution, any solution such as $z=\psi(x, y)$ will necessarily be associated with the equations $p=dz/dx$, $q=dz/dy$, and $z$ will satisfy the equation in its original form. We have previously seen (under *Pfaffian Expressions*) that if five variables $xyzpq$, otherwise independent, be subject to $dz-pdx-qdy=0$, they must in fact be subject to at least three mutual relations. If we associate with a point $xyz$ the plane $Z-z=p(X-x)+q(Y-y)$ passing through it, where X, Y, Z are current co-ordinates, and call this association a surface-element; and if two consecutive elements of which the point $(x+dx, y+dy, z+dz)$ of one lies on the plane of the other, for which, that is, the condition $dz=pdx+qdy$ is satisfied, be said to be *connected*, and an infinity of connected elements following one another continuously be called a *connectivity*, then our statement is that a connectivity consists of not more than $\infty^2$ elements, the whole number of elements $(xyzpq)$ that are possible being called $\infty^5$. The solution of an equation $F(x, y, z, dz/dx, dz/dy)=0$ is then to be understood to mean finding in all possible ways, from the $\infty^4$ elements $(xyzpq)$ which satisfy $F(xyzpq)=0$

***Partial differential equation of the first order.***

a set of $\infty^2$ elements forming a connectivity; or, more analytically, finding in all possible ways two relations $G=0$, $H=0$ connecting $x$, $y$, $z$, $p$, $q$ and independent of $F=0$, so that the three relations together may involve $dz=pdx+qdy$. Such a set of three relations may, for example, be of the form $z=\psi(x, y)$, $p=d\psi/dx$, $q=d\psi/dy$; but it may also, as another case, involve two relations $z=\psi(y)$, $x=\psi_1(y)$ connecting $x$, $y$, $z$, the third relation being $\psi'(y)=p\psi'_1(y)+q$, the connectivity consisting in that case, geometrically, of a curve in space taken with $\infty^1$ of its tangent planes; or, finally, a connectivity is constituted by a fixed point and all the planes passing through that point. This generalized view of the meaning of a solution of $F=0$ is of advantage, moreover, in view of anomalies otherwise arising from special forms of the equation itself. For instance, we may include the case, sometimes arising when the equation to be solved is obtained by transformation from another equation, in which F does not contain either $p$ or $q$. Then the equation has $\infty^2$ solutions, each consisting of an arbitrary point of the surface $F=0$ and all the $\infty^2$ planes passing through this point; it also has $\infty^2$ solutions, each consisting of a curve drawn on the surface $F=0$ and all the tangent planes of this curve, the whole consisting of $\infty^2$ elements; finally, it has also an isolated (or singular) solution consisting of the points of the surface, each associated with the tangent plane of the surface thereat, also $\infty^2$ elements in all. Or again, a linear equation $F=Pp+Qq-R=0$, wherein P, Q, R are functions of $x$, $y$, $z$ only, has $\infty^2$ solutions, each consisting of one of the curves defined by $dx/P=dy/Q=dz/R$ taken with all the tangent planes of this curve; and the same equation has $\infty^2$ solutions, each consisting of the points of a surface containing $\infty^1$ of these curves and the tangent planes of this surface. And for the case of $n$ variables there is similarly the possibility of $n+1$ kinds of solution of an equation $F(x_1 \cdots x_n z p_1 \cdots p_n)=0$; these can, however, by a simple contact transformation be reduced to one kind, in which there is only one relation $z'=\psi(x'_1 \cdots x'_n)$ connecting the new variables $x'_1 \cdots x'_n z'$ (see under *Pfaffian Expressions*); just as in the case of the solution $z=\psi(y)$, $x=\psi_1(y)$, $\psi'(y)=p\psi'_1(y)+q$ of the equation $Pp+Qq=R$ the transformation $z'=z-px$, $x'=p$, $p'=-x$, $y'=y$, $q'=q$ gives the solution $z'=\psi(y')+x'\psi_1(y')$, $p'=dz'/dx'$, $q'=dz'/dy'$ of the transformed equation. These explanations take no account of the possibility of $p$ and $q$ being infinite; this can be dealt with by writing $p=-u/w$, $q=-v/w$, and considering homogeneous equations in $u$, $v$, $w$, with $udx+vdy+wdz=0$ as the differential relation necessary for a connectivity; in practice we use the ideas associated with such a procedure more often without the appropriate notation.

***Meaning of a solution of the equation.***

In utilizing these general notions we shall first consider the theory of characteristic chains, initiated by Cauchy, which shows well the nature of the relations implied by the given differential equation; the alternative ways of carrying out the necessary integrations are suggested by considering the method of Jacobi and Mayer, while a good summary is obtained by the formulation in terms of a Pfaffian expression.

***Order of the ideas.***

Consider a solution of $F=0$ expressed by the three independent equations $F=0$, $G=0$, $H=0$. If it be a solution in which there is more than one relation connecting $x$, $y$, $z$, let new variables $x'y'z'p'q'$ be introduced, as before explained under *Pfaffian Expressions*, in which $z'$ is of the form $z'=z-p_1x_1-\cdots-p\,x_s$ ($s=1$ or 2), so that the solution becomes of a form $z'=\psi(x'y')$, $p'=d\psi/dx'$, $q'=d\psi/dy'$, which then will identically satisfy the transformed equations $F'=0$, $G'=0$, $H'=0$. The equation $F'=0$, if $x'y'z'$ be regarded as fixed, expresses that the plane $Z-z'=p'(X-x')+q'(Y-y')$ is tangent to a certain cone whose vertex is $x'y'z'$, the consecutive point $(x'+dx', y'+dz', z'+dz')$ of the generator of contact being such that $dx'\Big/\dfrac{dF'}{dp'}=dy'\Big/\dfrac{dF'}{dq'}=dz'\Big/\left(p'\dfrac{dF'}{dp'}+q'\dfrac{dF'}{dq'}\right)$. Passing in this direction on the surface $z'=\psi(x'y')$ the tangent plane of the surface at this consecutive point is $(p'+dp', q'+dq')$, where, since $F'(x', y', \psi, d\psi/dx', d\psi/dy')=0$ is identical, we have $dx'(dF'/dx'+p'dF'/dz')+dp'dF'/dp'=0$. Thus the equations, which we shall call the characteristic equations,

$$dx'\Big/\frac{dF'}{dp'}=dy'\Big/\frac{dF'}{dq'}=dz'\Big/\left(p'\frac{dF'}{dp'}+q'\frac{dF'}{dq'}\right)=dp'\Big/\left(-\frac{dF'}{dx'}-p'\frac{dF'}{dz'}\right)=dq'\Big/\left(-\frac{dF'}{dy'}-q'\frac{dF'}{dz'}\right)$$

are satisfied along a connectivity of $\infty^1$ elements consisting of a curve on $z'=\psi(x'y')$ and the tangent planes of the surface along this curve. The equation $F'=0$, when $p'$, $q'$ are fixed, represents a curve in the plane $Z-z'=p'(X-x')+q'(Y-y')$, passing through $x'y'z'$; if $(x'+\delta x', y'+\delta y', z'+\delta z')$ be a consecutive point of this curve, we find at once $\delta x'\left(\dfrac{dF'}{dx'}+p'\dfrac{dF'}{dz'}\right)+\delta y'\left(\dfrac{dF'}{dy'}+q'\dfrac{dF'}{dz'}\right)=0$; thus the equations above give $\delta x'dp'+\delta y'dq'=0$, or the tangent line of the plane curve, is, on the surface $z'=\psi(x'y')$, in a direction conjugate to that of the generator of the cone. Putting each of the fractions in the characteristic equations equal to $dt$, the equations enable us, starting from an arbitrary element $x'_0y'_0z'_0p'_0q'_0$ about which all the quantities $F'$, $dF'/dp'$, etc., occurring in the denominators, are developable, to define, from the differential equation $F'=0$ alone, a connectivity of $\infty^1$ elements, which we call a *characteristic chain*; and it is remarkable that when we transform again to the original variables $(xyzpq)$, the form of the differential equations for the chain is unaltered, so that they can be written down at once from the equation $F=0$. Thus we have proved that the characteristic chain starting from any ordinary element of any integral of this equation $F=0$ consists only of elements belonging to this integral. For instance, if the equation do not contain $p$, $q$, the characteristic chain, starting from an arbitrary plane through an arbitrary point of the surface $F=0$, consists of a pencil of planes whose axis is a tangent line of the surface $F=0$. Or if $F=0$ be of the form $Pp+Qq=R$, the chain consists of a curve satisfying $dx/P=dy/Q=dz/R$ and a single infinity of tangent planes of this curve, determined by the tangent plane chosen at the initial point. In all cases there are $\infty^3$ characteristic chains, whose aggregate may therefore be expected to exhaust the $\infty^4$ elements satisfying $F=0$.

***Characteristic chains.***

Consider, in fact, a single infinity of connected elements each satisfying $F=0$, say a chain connectivity T, consisting of elements specified by $x_0y_0z_0p_0q_0$, which we suppose expressed as functions of a parameter $u$, so that $U_0=dz_0/du-p_0dx_0/du-q_0dy_0/du$ is everywhere zero on this chain; further, suppose that each of $F$, $dF/dp$, $\cdots$, $dF/dx+pdF/dz$ is developable about each element of this chain T, and that T is *not* a characteristic chain. Then consider the aggregate of the characteristic chains issuing from all the elements of T. The $\infty^2$ elements, consisting of the aggregate of these characteristic chains, satisfy $F=0$, provided the chain connectivity T consists of elements satisfying $F=0$; for each characteristic chain satisfies $dF=0$. It can be shown that these chains are connected; in other words, that if $xyzpq$ be any element of one of these characteristic chains, not only is $dz/dt-pdx/dt-qdy/dt=0$, as we know, but also $U=dz/du-pdx/du-qdy/du$ is also zero. For we have

$$\frac{dU}{dt}=\frac{d}{dt}\left(\frac{dz}{du}-p\frac{dx}{du}-q\frac{dy}{du}\right)-\frac{d}{du}\left(\frac{dz}{dt}-p\frac{dx}{dt}-q\frac{dy}{dt}\right)=\frac{dp}{du}\frac{dx}{dt}-\frac{dp}{dt}\frac{dx}{du}+\frac{dq}{du}\frac{dy}{dt}-\frac{dq}{dt}\frac{dy}{du},$$

which is equal to

$$\frac{dp}{du}\frac{dF}{dp}+\frac{dx}{du}\left(\frac{dF}{dx}+p\frac{dF}{dz}\right)+\frac{dq}{du}\frac{dF}{dq}+\frac{dy}{du}\left(\frac{dF}{dy}+q\frac{dF}{dz}\right)=-\frac{dF}{dz}.U.$$

As $\dfrac{dF}{dz}$ is a developable function of $t$, this, giving $U=U_0\, exp\left(-\displaystyle\int_{t_0}^{t}\frac{dF}{dz}dt\right)$, shows that U is everywhere zero. Thus integrals of $F=0$ are obtainable by considering the aggregate of characteristic chains issuing from arbitrary chain connectivities T satisfying $F=0$; and such connectivities T are, it is seen at once, determinable without integration. Conversely, as such a chain connectivity T can be taken out from the elements of any given integral all possible integrals are obtainable in this way. For instance, an arbitrary curve in space, given by $x_0=\theta(u)$, $y_0=\phi(u)$, $z_0=\psi(u)$, determines by the two equations $F(x_0y_0z_0p_0q_0)=0$, $\psi'(u)=p_0\theta'(u)+q_0\phi'(u)$, such a chain connectivity T, through which there passes a perfectly definite integral of the equation $F=0$. By taking $\infty^2$ initial chain connectivities T, as for instance by taking the curves $x_0=\theta$, $y_0=\phi$, $z_0=\psi$ to be the $\infty^2$ curves upon an arbitrary surface, we thus obtain $\infty^2$ integrals, and so $\infty^4$ elements:

***Complete integral constructed with characteristic chains.***

satisfying $F=0$. In general, if functions G, H, independent of F, be obtained, such that the equations $F=0$, $G=b$, $H=c$ represent an integral for all values of the constants $b$, $c$, these equations are said to constitute a *complete integral*. Then $\infty^4$ elements satisfying $F=0$ are known, and in fact every other form of integral can be obtained without further integrations.

In the foregoing discussion of the differential equations of a characteristic chain, the denominators $\frac{dF}{dp}, \cdot\cdot$ may be supposed to be modified in form by means of $F=0$ in any way conducive to a simple integration. In the immediately following explanation of ideas, however, we consider indifferently all equations $F=$ constant; when a function of $xyzpq$ is said to be zero, it is meant that this is so identically, not in virtue of $F=0$; in other words, we consider the integration of $F=a$, where $a$ is an arbitrary constant. In the theory of linear partial equations we have seen that the integration of the equations of the characteristic chains, from which, as has just been seen, that of the equation $F=a$ follows at once, would be involved in completely integrating the single linear homogeneous partial differential equation of the first order $[Ff]=0$, where the notation is that explained above under *Contact Transformations*.

***Operations necessary for integration of F=a.***

One obvious integral is $f=F$. Putting $F=a$, where $a$ is arbitrary, and eliminating one of the independent variables, we can reduce this equation $[Ff]=0$ to one in four variables; and so on. Calling, then, the determination of a single integral of a single homogeneous partial differential equation of the first order in $n$ independent variables, *an operation of order* $n-1$, the characteristic chains, and therefore the most general integral of $F=a$, can be obtained by successive operations of orders 3, 2, 1. If, however, an integral of $F=a$ be represented by $F=a$, $G=b$, $H=c$, where $b$ and $c$ are arbitrary constants, the expression of the fact that a characteristic chain of $F=a$ satisfies $dG=0$, gives $[FG]=0$; similarly, $[FH]=0$ and $[GH]=0$, these three relations being identically true. Conversely, suppose that an integral G, independent of F, has been obtained of the equation $[Ff]=0$, which is an operation of order three. Then it follows from the identity $[f[\phi\psi]]+[\phi[\psi f]]+[\psi[f\phi]]=\frac{df}{dz}[\psi\phi]+\frac{d\phi}{dz}[\psi f]+\frac{d\psi}{dz}[f\phi]$ before remarked, by putting $\phi=F$, $\psi=G$, and then $[Ff]=A(f)$, $[Gf]=B(f)$, that $AB(f)-BA(f)=\frac{dF}{dz}B(f)-\frac{dG}{dz}A(f)$, so that the two linear equations $[Ff]=0$, $[Gf]=0$ form a complete system; as two integrals F, G are known, they have a common integral H, independent of F, G, determinable by an operation of order one only. The three functions F, G, H thus identically satisfy the relations $[FG]=[GH]=[FH]=0$. The $\infty^2$ elements satisfying $F=a$, $G=b$, $H=c$, wherein $a$, $b$, $c$ are assigned constants, can then be seen to constitute an integral of $F=a$. For the conditions that a characteristic chain of $G=b$ issuing from an element satisfying $F=a$, $G=b$, $H=c$ should consist only of elements satisfying these three equations are simply $[FG]=0$ $[GH]=0$. Thus, starting from an arbitrary element of ($F=a$, $G=b$, $H=c$), we can single out a connectivity of elements of ($F=a$, $G=b$, $H=c$) forming a characteristic chain of $G=b$; then the aggregate of the characteristic chains of $F=a$ issuing from the elements of this characteristic chain of $G=b$ will be a connectivity consisting only of elements of ($F=a$, $G=b$, $H=c$), and will therefore constitute an integral of $F=a$; further, it will include all elements of ($F=a$, $G=b$, $H=c$). This result follows also from a theorem given under *Contact Transformations*, which shows, moreover, that though the characteristic chains of $F=a$ are not determined by the three equations $F=a$, $G=b$, $H=c$, no further integration is now necessary to find them. By this theorem, since identically $[FG]=[GH]=[FH]=0$, we can find, by the solution of linear algebraic equations only, a non-vanishing function $\sigma$ and two functions A, C, such that $dG-AdF-CdH=\sigma(dz-pdx-qdy)$; thus all the elements satisfying $F=a$, $G=b$, $H=c$, satisfy $dz=pdx+qdy$ and constitute a connectivity, which is therefore an integral of $F=a$. While, further, from the associated theorems, F, G, H, A, C are independent functions and $[FC]=0$. Thus C may be taken to be the remaining integral independent of G, H, of the equation $[Ff]=0$, whereby the characteristic chains are entirely determined.

When we consider the particular equation $F=0$, neglecting the case when neither $p$ nor $q$ enters, and supposing $p$ to enter, we may express $p$ from $F=0$ in terms of $xyzq$, and then eliminate it from all other equations. Then instead of the equation $[Ff]=0$, we have, if $F=0$ give $p=\psi(xyzq)$, the equation $\Omega f=-\left(\frac{df}{dx}+\psi\frac{df}{dz}\right)+\frac{d\psi}{dq}\left(\frac{df}{dy}+q\frac{df}{dz}\right)-\left(\frac{d\psi}{dy}+q\frac{d\psi}{dz}\right)\frac{df}{dq}=0$, moreover obtainable by omitting the term in $\frac{df}{dp}$ in $[p-\psi, f]=0$. Let $x_o y_o z_o q_o$ be values about which the coefficients in this equation are developable, and let $\zeta$, $\eta$, $\omega$ be the principal solutions reducing respectively to $z$, $y$ and $q$ when $x=x_o$. Then the equations $p=\psi$, $\zeta=z_o$, $\eta=y_o$, $\omega=q_o$ represent a characteristic chain issuing from the element $x_o y_o z_o \psi_o q_o$; we have seen that the aggregate of such chains issuing from the elements of an arbitrary chain satisfying $dz_o-p_o dx_o-q_o dy_o=0$ constitute an integral of the equation $p=\psi$. Let this arbitrary chain be taken so that $x_o$ is constant; then the condition for initial values is only $dz_o-q_o dy_o=0$, and the elements of the integral constituted by the characteristic chains issuing therefrom satisfy $d\zeta-\omega d\eta=0$. Hence this equation involves $dz-\psi dx-qdy=0$, or we have $dz-\psi dx-qdy=\sigma(d\zeta-\omega d\eta)$, where $\sigma$ is not zero. Conversely, the integration of $p=\psi$ is, essentially, the problem of writing the expression $dz-\psi dx-qdy$ in the form $\sigma(d\zeta-\omega d\eta)$, as must be possible (from what was said under *Pfaffian Expressions*).

***The single equation F=0 and Pfaffian formulation.***

To integrate a system of simultaneous equations of the first order $X_1=a_1 \cdot\cdot\cdot X_r=a_r$ in $n$ independent variables $x_1 \cdot\cdot x_n$ and one dependent variable $z$, we write $p_1$ for $dz/dx_1$, &c., and attempt to find $n+1-r$ further functions Z, $X_{r+1} \cdot\cdot X_n$, such that the equations $Z=a$, $X_i=a_i (i=1 \cdot\cdot n)$ involve $dz-p_1dx_1-\cdot\cdot\cdot-p_ndx_n=0$. By an argument already given, the common integral, if existent, must be satisfied by the equations of the characteristic chains of any one equation $X_i=a_i$; thus each of the expressions $[X_iX_j]$ must vanish in virtue of the equations expressing the integral, and we may without loss of generality assume that each of the corresponding $\frac{1}{2}r(r-1)$ expressions formed from the $r$ given differential equations vanishes in virtue of these equations. The determination of the remaining $n+1-r$ functions may, as before, be made to depend on characteristic chains, which in this case, however, are manifolds of $r$ dimensions obtained by integrating the equations $[X_1f]=0 \cdot\cdot\cdot [X_rf]=0$; or having obtained one integral of this system other than $X_1 \cdot\cdot X_r$, say $X_{r+1}$, we may consider the system $[X_1f]=0 \cdot\cdot [X_{r+1}f]=0$, for which, again, we have a choice; and at any stage we may use Mayer's method and reduce the simultaneous linear equations to one equation involving parameters; while if at any stage of the process we find some but not all of the integrals of the simultaneous system, they can be used to simplify the remaining work; this can only be clearly explained in connexion with the theory of so-called function groups for which we have no space. One result arising is that the simultaneous system $p_1=\phi_1, \cdot\cdot, p_r=\phi_r$, wherein $p_1 \cdot\cdot p_r$ are not involved in $\phi_1 \cdot\cdot \phi_r$, if it satisfies the $\frac{1}{2}r(r-1)$ relations $[p_i-\phi_i, p_j-\phi_j]=0$, has a solution $z=\psi(x_1 \cdot\cdot x_n)$, $p_1=d\psi/dx_1 \cdot\cdot$, $p_n=d\psi/dx_n$, reducing to an arbitrary function, of $x_{r+1} \cdot\cdot\cdot x_n$ only, when $x_1=x_1^o \cdot\cdot x_r=x_r^o$ under certain conditions as to developability; a generalization of the theorem for linear equations. The problem of integration of this system is, as before, to put $dz-\phi_1dx_1-\cdot\cdot\cdot-\phi_rdx_r-p_{r+1}dx_{r+1}-\cdot\cdot\cdot-p_n\,dx_n$ into the form $\sigma(d\zeta-\omega_{r+1}d\xi_{r+1}-\cdot\cdot\cdot\omega_nd\xi_n)$; and here $\zeta$, $\xi_{r+1} \cdot\cdot \xi_n$ $\omega_{r+1} \cdot\cdot\cdot \omega_n$ may be taken, as before, to be principal integrals of a certain complete system of linear equations; those, namely, determining the characteristic chains.

***System of equations of the first order.***

If L be a function of $t$ and of the $2n$ quantities $x_1 \cdot\cdot x_n \dot{x}_1 \cdot\cdot \dot{x}_n$, where $\dot{x}_i$ denotes $dx_i/dt$, &c., and if in the $n$ equations $\frac{d}{dt}\left(\frac{dL}{d\dot{x}_i}\right)=\frac{dL}{dx_i}$ we put $p_i=\frac{dL}{d\dot{x}_i}$, and so express $\dot{x}_1 \cdot\cdot \dot{x}_n$ in terms of $t$, $x_1 \cdot\cdot x_n p_1 \cdot\cdot p_n$, assuming that the determinant of the quantities $\frac{d^2L}{d\dot{x}_i\,d\dot{x}_j}$ is not zero; if, further, H denote the function of $t$, $x_1 \cdot\cdot x_n p_1 \cdot\cdot p_n$, numerically equal to $p_1\dot{x}_1+\cdot\cdot+p_n\dot{x}_n-L$, it is easy to prove that $dp_i/dt=-dH/dx_i$, $dx_i/dt=dH/dp_i$. These so-called *canonical* equations form part of those for the characteristic chains of the single partial equation $dz/dt+H(tx_1 \cdot\cdot x_n, dz/dx_1, \cdot\cdot\cdot, dz/dx_n)=0$, to which then the solution of the original equations for $x_1 \cdot\cdot x_n$ can be reduced. It may be shown (1) that if $z=\psi(tx_1 \cdot\cdot x_nc_1 \cdot\cdot c_n)+c$ be a complete integral of this equation, then $p_i=d\psi/dx_i$, $d\psi/dc_i=e_i$ are $2n$ equations giving the solution of the canonical equations referred to, where $c_1 \cdot\cdot c_n$ and $e_1 \cdot\cdot e_n$ are arbitrary constants; (2) that if $x_i=X_i(tx_1^o \cdot\cdot p_n^o)$, $p_i=P_i(tx_1^o \cdot\cdot p_n^o)$ be the principal solutions of the canonical equations for $t=t^o$, and $\omega$ denote the result of substituting these values in $p_1dH/dp_1+\cdot\cdot\cdot+p_ndH/dp_n-H$, and $\Omega=\int_{t_o}^{t}\omega dt$, where, after integration, $\Omega$ is to be expressed as a function of $t$, $x_1 \cdot\cdot x_nx_1^o \cdot\cdot x_n^o$, then $z=\Omega+z^o$ is a complete integral of the partial equation.

***Equations of dynamics.***

A system of differential equations is said to allow a certain continuous group of transformations (see GROUPS) when the introduction for the variables in the differential equations of the new variables arising in the general finite equations of the group leads, for all values of the parameters of the group, to the same differential equations in the new variables. It would be interesting

to verify in examples that this is the case in at least the majority of the differential equations which are known to be integrable in finite terms. As space forbids the attempt, we give a theorem of very general application for the case of a simultaneous complete system of linear partial homogeneous differential equations of the first order, to the solution of which the various differential equations discussed have been reduced. It will be enough to consider whether the given differential equations allow the infinitesimal transformations of the group.

***Application of theory of continuous groups to formal theories.***

It can be shown easily that sufficient conditions in order that a complete system $\Pi_1 f=0 \cdot\cdot \Pi_k f=0$, in $n$ independent variables, should allow the infinitesimal transformation $\mathrm{P}f=0$ are expressed by $k$ equations $\Pi_i \mathrm{P}f - \mathrm{P}\Pi_i f = \lambda_{i1}\Pi_1 f + \cdot\cdot + \lambda_{ik}\Pi_k f$. Suppose now a complete system of $n-r$ equations in $n$ variables to allow a group of $r$ infinitesimal transformations $(\mathrm{P}_1 f, \cdot\cdot, \mathrm{P}_r f)$ which has an invariant subgroup of $r-1$ parameters $(\mathrm{P}_1 f, \cdot\cdot, \mathrm{P}_{r-1} f)$, it being supposed that the $n$ quantities $\Pi_1 f, \cdot\cdot, \Pi_{n-r} f, \mathrm{P}_1 f, \cdot\cdot, \mathrm{P}_r f$ are not connected by an identical linear equation (with coefficients even depending on the independent variables). Then it can be shown that one solution of the complete system is determinable by a quadrature. For each of $\Pi_i \mathrm{P}_\sigma f - \mathrm{P}_\sigma \Pi_i f$ is a linear function of $\Pi_1 f, \cdot\cdot, \Pi_{n-r} f$ and the simultaneous system of independent equations $\Pi_1 f=0 \cdot\cdot \Pi_{n-r} f=0, \mathrm{P}_1 f=0 \cdot\cdot \mathrm{P}_{r-1} f=0$ is therefore a complete system, allowing the infinitesimal transformation $\mathrm{P}_r f$. This complete system of $n-1$ equations has therefore one common solution $\omega$, and $\mathrm{P}_r(\omega)$ is a function of $\omega$. By choosing $\omega$ suitably, we can then make $\mathrm{P}_r(\omega)=1$. From this equation and the $n-1$ equations $\Pi_i\omega=0$, $\mathrm{P}_\sigma\omega=0$, we can determine $\omega$ by a quadrature only. Hence can be deduced a much more general result, *that if the group of* r *parameters be integrable, the complete system can be entirely solved by quadratures*; it is only necessary to introduce the solution found by the first quadrature as an independent variable, whereby we obtain a complete system of $n-r$ equations in $n-1$ variables, subject to an integrable group of $r-1$ parameters, and to continue this process. We give some examples of the application of the theorem. (1) If an equation of the first order $y'=\psi(x, y)$ allow the infinitesimal transformation $\xi df/dx+\eta df/dy$, the integral curves $\omega(x, y)=y^o$, wherein $\omega(x, y)$ is the solution of $\dfrac{df}{dx}+\psi(x, y)\dfrac{df}{dy}=0$ reducing to $y$ for $x=x^o$, are interchanged among themselves by the infinitesimal transformation, or $\omega(x, y)$ can be chosen to make $\xi d\omega/dx+\eta d\omega/dy=1$; this, with $d\omega/dx+\psi d\omega/dy=0$, determines $\omega$ as the integral of the complete differential $(dy-\psi dx)/(\eta-\psi\xi)$. This result itself shows that every ordinary differential equation of the first order is subject to an infinite number of infinitesimal transformations. But every infinitesimal transformation $\xi df/dx+\eta df/dy$ can by change of variables (after integration) be brought to the form $df/dy$, and all differential equations of the first order allowing this group can then be reduced to the form $\mathrm{F}(x, dy/dx)=0$. (2) In the case of an ordinary equation of the second order $y''=\psi(xyy')$, equivalent to $dy/dx=y_1$, $dy_1/dx=\psi(xyy_1)$, if $\mathrm{H}, \mathrm{H}_1$ be the solutions for $y$ and $y_1$ chosen to reduce to $y^o$ and $y_1{}^o$ when $x=x^o$, and the equations $\mathrm{H}=y$, $\mathrm{H}_1=y_1$ be equivalent to $\omega=y^o$, $\omega_1=y_1{}^o$, then $\omega$, $\omega_1$ are the principal solutions of $\Pi f=df/dx+y_1 df/dy+\psi df/dy_1=0$. If the original equation allow an infinitesimal transformation whose first *extended* form (see art. GROUPS) is $\mathrm{P}f=\xi df/dx+\eta df/dy+\eta_1 df/dy_1$, where $\eta_1\delta t$ is the increment of $dy/dx$ when $\xi\delta t$, $\eta\delta t$ are the increments of $x$, $y$, and is to be expressed in terms of $x$, $y$, $y_1$, then each of $\mathrm{P}\omega$ and $\mathrm{P}\omega_1$ must be functions of $\omega$ and $\omega_1$, or the partial differential equation $\Pi f$ must allow the group $\mathrm{P}f$. Thus by our general theorem, if the differential equation allow a group of two parameters (and such a group is always integrable), it can be solved by quadratures, our explanation sufficing, however, only provided the form $\Pi f$ and the two infinitesimal transformations are not linearly connected. It can be shown, from the fact that $\eta_1$ is a quadratic polynomial in $y_1$, that no differential equation of the second order can allow more than 8 really independent infinitesimal transformations, and that every homogeneous linear differential equation of the second order allows just 8, being in fact reducible to $d^2y/dx^2=0$. Since every group of more than two parameters has subgroups of two parameters, a differential equation of the second order allowing a group of more than two parameters can, as a rule, be solved by quadratures. By transforming the group we see that if a differential equation of the second order allows a single infinitesimal transformation, it can be transformed to the form $\mathrm{F}(x, d\gamma/dx, d^2\gamma/dx^2)$; this is not the case for every differential equation of the second order. (3) For an ordinary differential equation of the third order, allowing an integrable group of three parameters whose infinitesimal transformations are not linearly connected with the partial equation to which the solution of the given ordinary equation is reducible, the similar result follows that it can be integrated by quadratures. But if the group of three parameters be simple, this result must be replaced by the statement that the integration is reducible to quadratures and that of a so-called Riccati equation of the first order, of the form $dy/dx=\mathrm{A}+\mathrm{B}y+\mathrm{C}y^2$, where A, B, C are functions of $x$. (4) Similarly for the integration by quadratures of an ordinary equation $y_n=\psi(xyy_1 \cdot\cdot y_{n-1})$ of any order. Moreover, the group allowed by the equation may quite well consist of extended contact transformations. An important application is to the case where the differential equation is the resolvent equation defining the group of transformations or rationality group of another differential equation (see below); in particular, when the rationality group of an ordinary linear differential equation is integrable, the equation can be solved by quadratures.

***Consideration of function theories of differential equations.***

Following the practical and provisional division of theories of differential equations, to which we alluded at starting, into transformation theories and function theories, we pass now to give some account of the latter. These are both a necessary logical complement of the former, and the only remaining resource when the expedients of the former have been exhausted. While in the former investigations we have dealt only with values of the independent variables about which the functions are developable, the leading idea now becomes, as was long ago remarked by G. Green, the consideration of the neighbourhood of the values of the variables for which this developable character ceases. Beginning, as before, with existence theorems applicable for ordinary values of the variables, we are to consider the cases of failure of such theorems.

***A general existence theorem.***

When in a given set of differential equations the number of equations is greater than the number of dependent variables, the equations cannot be expected to have common solutions unless certain conditions of compatibility, obtainable by equating different forms of the same differential coefficients deducible from the equations, are satisfied. We have had examples in systems of linear equations, and in the case of a set of equations $p_1=\phi_1, \cdot\cdot, p_r=\phi_r$. For the case when the number of equations is the same as that of dependent variables, the following is a general theorem which should be referred to: Let there be $r$ equations in $r$ dependent variables $z_1 \cdot\cdot z_r$ and $n$ independent variables $x_1 \cdot\cdot x_n$; let the differential coefficient of $z_\sigma$ of highest order which enters be of order $h_\sigma$, and suppose $d^{h_\sigma}z_\sigma/dx_1{}^{h_\sigma}$ to enter, so that the equations can be written $d^{h_\sigma}z_\sigma/dx_1{}^{h_\sigma}=\Phi_\sigma$, where in the general differential coefficient of $z_\rho$ which enters in $\Phi_\sigma$, say $d^{k_1+\cdot\cdot+k_n}z_\rho/dx_1{}^{k_1}\cdot\cdot dx_n{}^{k_n}$, we have $k_1 < h_\rho$ and $k_1+\cdot\cdot+k_n \leqq h_\rho$. Let $a_1 \cdot\cdot a_n b_1 \cdot\cdot b_r$ and $b^\rho{}_{k_1 \cdot\cdot k_n}$ be a set of values of $x_1 \cdot\cdot x_n z_1 \cdot\cdot z_r$ and of the differential coefficients entering in $\Phi_\sigma$ about which all the functions $\Phi_1 \cdot\cdot \Phi_r$ are developable. Corresponding to each dependent variable $z_\sigma$, we take now a set of $h_\sigma$ functions of $x_2 \cdot\cdot x_n$, say $\phi_\sigma, \phi_\sigma{}^{(1)}, \cdots, \phi_\sigma{}^{(h-1)}$, arbitrary save that they must be developable about $a_2 a_3 \cdot\cdot a_n$, and such that for these values of $x_2 \cdot\cdot x_n$, the function $\phi_\rho$ reduces to $b_\rho$, and the differential coefficient $d^{k_2+\cdot\cdot+k_n}\phi_\rho{}^{(k_1)}/dx_2{}^{k_2}\cdot\cdot dx_n{}^{k_n}$ reduces to $b_{k_1}{}^\rho{}_{\cdot\cdot k_n}$. Then the theorem is that there exists one, and only one, set of functions $z_1 \cdot\cdot z_r$ of $x_1 \cdot\cdot x_n$ developable about $a_1 \cdot\cdot a_n$ satisfying the given differential equations, and such that for $x_1=a_1$ we have $z_\sigma=\phi_\sigma$, $dz_\sigma/dx_1=\phi_\sigma{}^{(1)} \cdots d^{h_\sigma-1}z_\sigma/d^{h_\sigma-1}x_1=\phi_\sigma{}^{(h_\sigma-1)}$. And, moreover, if the arbitrary functions $\phi_\sigma\phi_\sigma{}^{(1)}\cdots$ contain a certain number of arbitrary variables $t_1 \cdot\cdot t_m$, and be developable about the values $t_1{}^o \cdot\cdot t_m{}^o$ of these variables, the solutions $z_1 \cdot\cdot z_r$ will contain $t_1 \cdot\cdot t_m$, and be developable about $t_1{}^o \cdot\cdot t_m{}^o$.

The proof of this theorem may be given by showing that if ordinary power series in $x_1-a_1 \cdot\cdot x_n-a_n\ t_1-t_1{}^o \cdot\cdot t_m-t_m{}^o$ be substituted in the equations wherein in $z_\sigma$ the coefficients of $(x_1-a_1)^o$, $x_1-a_1, \cdots, (x_1-a_1)^{h_\sigma-1}$ are the arbitrary functions $\phi_\sigma\phi_\sigma{}^{(1)}\cdot\cdot\phi_\sigma{}^{(h-1)}$,

divided respectively by 1, 1!, 2!, &c., then the differential equations determine uniquely all the other coefficients, and that the resulting series are convergent. We rely, in fact, upon the theory of monogenic analytical functions (see art. FUNCTIONS, ANALYTIC), a function being determined entirely by its development in the neighbourhood of one set of values of the independent variables, from which all its other values arise by *continuation*; it being of course understood that the coefficients in the differential equations are to be continued at the same time. But it is to be remarked that there is no ground for believing, if this method of continuation be utilized, that the function is single-valued; we may quite well return to the same values of the independent variables with a different value of the function, belonging, as we say, to a different branch of the function; and there is even no reason for assuming that the number of branches is finite, or that different branches have the same singular points and regions of existence. Moreover, and this is the most difficult consideration of all, all these circumstances may be dependent upon the values supposed given to the arbitrary constants of the integral; in other words, the singular points may be either *fixed*, being determined by the differential equations themselves, or they may be *movable* with the variation of the arbitrary constants of integration. Such difficulties arise even in establishing the reversion of an elliptic integral, in solving the equation $\left(\frac{dx}{ds}\right)^2=(x-a_1)(x-a_2)(x-a_3)(x-a_4)$; about an ordinary value the right side is developable; if we put $x-a_1=t_1^2$, the right side becomes developable about $t_1=0$; if we put $x=1/t$, the right side of the changed equation is developable about $t=0$; it is quite easy to show that the integral reducing to a definite value $x_o$ for a value $s_o$ is obtainable by a series in integral powers; this, however, must be supplemented by showing that for no values of $s$ does the value of $x$ become entirely undetermined.

**Singular points of solutions.**

These remarks will show the place of the theory now to be sketched of a particular class of ordinary linear homogeneous differential equations whose importance arises from the completeness and generality with which they can be discussed. We have seen that if in the equations $dy/dx=y_1$, $dy_1/dx=y_2, \cdots, dy_{n-2}/dx=y_{n-1}$, $dy_{n-1}/dx=a_n y+a_{n-1}y_1+\cdots+a_1 y_{n-1}$, wherein $a_1, a_2, \cdots, a_n$ are now to be taken to be rational functions of $x$, the value $x=x^o$ be one for which no one of these rational functions is infinite, and $y^o, y_1^o, \cdots, y^o_{n-1}$ be quite arbitrary finite values, then the equations are satisfied by $y=y^o u+y_1^o u_1+\cdots+y^o_{n-1}u_{n-1}$, wherein $u, u_1, \cdots, u_{n-1}$ are functions of $x$, independent of $y^o\cdots y^o_{n-1}$, developable about $x=x^o$; this value of $y$ is such that for $x=x^o$ the functions $y, y_1\cdots y_{n-1}$ reduce respectively to $y^o y_1^o \cdots y^o_{n-1}$; it can be proved that the region of existence of these series extends within a circle centre $x^o$ and radius equal to the distance from $x^o$ of the nearest point at which one of $a_1\cdots a_n$ becomes infinite. Now consider a region enclosing $x^o$, and only one of the places, say $\Sigma$, at which one of $a_1\cdots a_n$ becomes infinite. When $x$ is made to describe a closed curve in this region, including this point $\Sigma$ in its interior, it may well happen that the continuations of the functions $u, u_1, \cdots, u_{n-1}$ give, when we have returned to the point $x$, values $v, v_1, \cdots, v_{n-1}$, so that the integral under consideration becomes changed to $y^o v+y_1^o v_1+\cdots+y^o_{n-1}v_{n-1}$. At $x^o$ let this branch and the corresponding values of $y_1\cdots y_{n-1}$ be $\eta^o\eta^o_1\cdots\eta^o_{n-1}$; then, as there is only one series satisfying the equation and reducing to $(\eta^o\eta^o_1\cdots\eta^o_{n-1})$ for $x=x^o$, and the coefficients in the differential equation are single-valued functions, we must have $\eta^o u+\eta_1^o u_1+\cdots+\eta^o_{n-1}u_{n-1}=y^o v+y^o_1 v_1+\cdots+y^o_{n-1}v_{n-1}$; as this holds for arbitrary values of $y^o\cdots y^o_{n-1}$, upon which $u\cdots u_{n-1}$ and $v\cdots v_{n-1}$ do not depend, it follows that each of $v\cdots v_{n-1}$ is a linear function of $u\cdots u_{n-1}$ with constant coefficients, say $v_i=A_{i1}u+\cdots+A_{in}u_{n-1}$. Then $y^o v+\cdots+y^o_{n-1}v_{n-1}=(\Sigma_i A_{i1}y^o_i)u+\cdots+(\Sigma_i A_{in}y^o_i)u_{n-1}$; this is equal to $\mu(y^o u+\cdots+y^o_{n-1}u_{n-1})$ if $\Sigma_i A_{ir}y^o_i=\mu y^o_{r-1}$; eliminating $y^o\cdots y^o_{n-1}$ from these linear equations, we have a determinantal equation of order $n$ for $\mu$; let $\mu_1$ be one of its roots; determining the ratios of $y^o y_1^o\cdots y^o_{n-1}$ to satisfy the linear equations, we have thus proved that there exists an integral, H, of the equation, which when continued round the point $\Sigma$ and back to the starting-point, becomes changed to $H_1=\mu_1 H$. Let now $\xi$ be the value of $x$ at $\Sigma$, and $r_1$ one of the values of $\frac{1}{2\pi i}\log\mu_1$; consider the function $(x-\xi)^{-r_1}H$; when $x$ makes a circuit round $x=\xi$, this becomes changed to $exp(-2\pi i r_1)(x-\xi)^{-r_1}\mu_1 H$, that is, is unchanged; thus we may put $H=(x-\xi)^{r_1}\phi_1$, $\phi_1$ being a function single-valued for paths in the region considered described about $\Sigma$, and therefore, by Laurent's Theorem (see art. FUNCTIONS, ANALYTIC), capable of expression in the annular region about this point by a series of positive and negative integral powers of $x-\xi$, which in general may contain an infinite number of negative powers; there is, however, no reason to suppose $r_1$ to be an integer, or even real. Thus, if all the roots of the determinantal equation in $\mu$ are different, we obtain $n$ integrals of the forms $(x-\xi)^{r_1}\phi_1, \cdots, (x-\xi)^{r_n}\phi_n$. In general we obtain as many integrals of this form as there are really different roots; and the problem arises to discover, in case a root be $k$ times repeated, $k-1$ equations of as simple a form as possible to replace the $k-1$ equations of the form $y^o v+\cdots+y^o_{n-1}v_{n-1}=\mu(y^o u+\cdots+y^o_{n-1}u_{n-1})$ which would have existed had the roots been different. The most natural method of obtaining a suggestion lies probably in remarking that if $r_2=r_1+h$, there is an integral $[(x-\xi)^{r_1+h}\phi_2-(x-\xi)^{r_1}\phi_1]/h$, wherein the coefficients in $\phi_2$ are the same functions of $r_1+h$ as are the coefficients in $\phi_1$ of $r_1$; when $h$ vanishes, this integral takes the form $(x-\xi)^{r_1}\left[\frac{d\phi_1}{dr_1}+\phi_1\log(x-\xi)\right]$, or say $(x-\xi)^{r_1}[\psi_1+\phi_1\log(x-\xi)]$; denoting this by $2\pi i\mu_1 K$, and $(x-\xi)^{r_1}\phi_1$ by H, a circuit of the point $\xi$ changes K into $K'=\frac{1}{2\pi i\mu_1}\left[e^{2\pi i r_1}(x-\xi)^{r_1}\psi_1+e^{2\pi i r_1}(x-\xi)^{r_1}\phi_1(2\pi i+\log(x-\xi))\right]=\mu_1 K+H$. A similar artifice suggests itself when three of the roots of the determinantal equation are the same, and so on. We are thus led to the result, which is justified by an examination of the algebraic conditions, that whatever may be the circumstances as to the roots of the determinantal equation, $n$ integrals exist, breaking up into batches, the values of the constituents $H_1, H_2, \cdots$ of a batch after circuit about $x=\xi$ being $H_1'=\mu_1 H_1$, $H_2'=\mu_1 H_2+H_1$, $H_3'=\mu_1 H_3+H_2$, and so on. And this is found to lead to the forms $(x-\xi)^{r_1}\phi_1$, $(x-\xi)^{r_1}[\psi_1+\phi_1\log(x-\xi)]$, $(x-\xi)^{r_1}[\chi_1+\chi_2\log(x-\xi)+\phi_1(\log(x-\xi))^2]$, and so on. Here each of $\phi_1\psi_1\chi_1\chi_2\cdots$ is a series of positive and negative integral powers of $x-\xi$ in which the number of negative powers may be infinite.

**Linear differential equations with rational coefficients.**

It appears natural enough now to inquire whether, under proper conditions for the forms of the rational functions $a_1\cdots a_n$, it may be possible to ensure that in each of the series $\phi_1\psi_1\chi_1\cdots$ the number of negative powers shall be finite. Herein lies, in fact, the limitation which experience has shown to be justified by the completeness of the results obtained. Assuming $n$ integrals in which in each of $\phi_1, \psi_1, \chi_1\cdots$ the number of negative powers is finite, there is a definite homogeneous linear differential equation having these integrals; this is found by forming it to have the form $y'^n=(x-\xi)^{-1}b_1 y'^{(n-1)}+(x-\xi)^{-2}b_2 y'^{(n-2)}+\cdots+(x-\xi)^{-n}b_n y$, where $b_1\cdots b_n$ are finite for $x=\xi$. Conversely, assume the equation to have this form. Then on substituting a series of the form $(x-\xi)^r[1+A_1(x-\xi)+A_2(x-\xi)^2+\cdots]$ and equating the coefficients of like powers of $x-\xi$, it is found that $r$ must be a root of an algebraic equation of order $n$; this equation, which we shall call the index equation, can be obtained at once by substituting for $y$ only $(x-\xi)^r$ and replacing each of $b_1\cdots b_n$ by their values at $x=\xi$; arrange the roots $r_1, r_2, \cdots$ of this equation so that the real part of $r_i$ is equal to, or greater than, the real part of $r_{i+1}$, and take $r$ equal to $r_1$; it is found that the coefficients $A_1, A_2\cdots$ are uniquely determinate, and that the series converges within a circle about $x=\xi$ which includes no other of the points at which the rational functions $a_1\cdots a_n$ become infinite. We have thus a solution $H_1=(x-\xi)^{r_1}\phi_1$ of the differential equation. If we now substitute in the equation $y=H_1\int\eta dx$, it is found to reduce to an equation of order $n-1$ for $\eta$ of the form $\eta'^{(n-1)}=(x-\xi)^{-1}c_1\eta'^{(n-2)}+\cdots+(x-\xi)^{n-1}c_{n-1}\eta$, wherein $c_1\cdots c_{n-1}$ are not infinite at $x=\xi$. To this equation precisely similar reasoning can then be applied; its index equation has in fact the roots $r_2-r_1-1, \cdots, r_n-r_1-1$; if $r_2-r_1$ be zero, the integral $(x-\xi)^{-1}\psi_1$ of the $\eta$ equation will give an integral of the original equation containing $\log(x-\xi)$; if $r_2-r_1$ be an integer, and therefore a negative integer, the same will be true, unless in $\psi_1$ the term in $(x-\xi)^{r_1-r_2}$ be absent; if neither of these arise, the original equation will have an integral $(x-\xi)^{r_2}\phi_2$. The $\eta$ equation can now, by means of the one integral of it belonging to the index $r_2-r_1-1$, be similarly reduced to one of order $n-2$, and so on. The result will be that stated above. We shall say that an equation of the form in question is *regular* about $x=\xi$.

**Regular equations.**

We may examine in this way the behaviour of the integrals at all the points at which any one of the rational functions $a_1\cdots a_n$ becomes infinite; in general we must expect that beside these the value $x=\infty$ will be a singular point for the solutions of the differential equation. To test this we put $x=1/t$ throughout, and examine as before at $t=0$. For instance, the ordinary linear equation with constant coefficients has no singular point for finite values of $x$; at $x=\infty$ it has a singular point and is not regular; or again, Bessel's equation $x^2y''+xy'+(x^2-n^2)y=0$ is regular about $x=0$, but not about $x=\infty$. An equation regular at all the finite singularities and also at $x=\infty$ is called a Fuchsian equation. We proceed to examine particularly the case of an equation of the second order $y''+ay'+by=0$. Putting $x=\frac{1}{t}$, it becomes $d^2y/dt^2+(2t^{-1}-at^{-2})dy/dt+bt^{-4}y=0$, which is not regular about $t=0$ unless $2-at^{-1}$ and $bt^{-2}$,

**Fuchsian equations.**

that is, unless $ax$ and $bx^2$ are finite at $x=\infty$; which we thus assume; putting $y=t^r(1+A_1t+\cdot\cdot)$, we find for the index equation at $x=\infty$ the equation $r(r-1)+r\ (2-ax)_o+(bx^2)_o=0$.

***Equation of the second order.***

If there be finite singular points at $\xi_1\cdot\cdot\xi_m$, where we assume $m>1$, the cases $m=0$, $m=1$ being easily dealt with, and if $\phi(x)=(x-\xi_1)\cdot\cdot\cdot(x-\xi_m)$, we must have $a\cdot\phi(x)$ and $b\cdot[\phi(x)]^2$ finite for all finite values of $x$, equal say to the respective polynomials $\psi(x)$ and $\theta(x)$, of which by the conditions at $x=\infty$, the highest respective orders possible are $m-1$ and $2(m-1)$. The index equation at $x=\xi_1$ is $r(r-1)+r\psi(\xi_1)/\phi'(\xi_1)+\theta(\xi_1)/[\phi'(\xi_1)]^2=0$, and if $\alpha_1$, $\beta_1$ be its roots, we have $\alpha_1+\beta_1=1-\psi(\xi_1)/\phi'(\xi_1)$ and $\alpha_1\beta_1=\theta(\xi_1)/[\phi'(\xi_1)]^2$. Thus by an elementary theorem of algebra, the sum $\Sigma(1-\alpha_i-\beta_i)/(x-\xi_i)$, extended to the $m$ finite singular points, is equal to $\psi(x)/\phi(x)$, and the sum $\Sigma(1-\alpha_i-\beta_i)$ is equal to the ratio of the coefficients of the highest powers of $x$ in $\psi(x)$ and $\phi(x)$, and therefore equal to $1+\alpha+\beta$, where $\alpha$, $\beta$ are the indices at $x=\infty$. Further, if $(x, 1)_{m-2}$ denote the integral part of the quotient $\theta(x)/\phi(x)$, we have $\Sigma\alpha_i\beta_i\phi'(\xi_i)/(x-\xi_i)$ equal to $-(x, 1)_{m-2}+\theta(x)/\phi(x)$, and the coefficient of $x^{m-2}$ in $(x, 1)_{m-2}$ is $\alpha\beta$. Thus the differential equation has the form $y''+y'\Sigma(1-\alpha_i-\beta_i)/(x-\xi_i)+y[(x,1)_{m-2}+\Sigma\alpha_i\beta_i\phi'(\xi_i)/(x-\xi_i)]/\phi(x)=0$. If, however, we make a change in the dependent variable, putting $y=(x-\xi_1)^{\alpha_1}\cdot\cdot(x-\xi_m)^{\alpha_m}\eta$, it is easy to see that the equation changes into one having the same singular points about each of which it is regular, and that the indices at $x=\xi_i$ become 0 and $\beta_i-\alpha_i$, which we shall denote by $\lambda_i$, for $(x-\xi_j)^{\alpha_j}$ can be developed in positive integral powers of $x-\xi_i$ about $x=\xi_i$; by this transformation the indices at $x=\infty$ are changed to $\alpha+\alpha_1+\cdot\cdot+\alpha_m$, $\beta+\beta_1+\cdot\cdot\cdot+\beta_m$ which we shall denote by $\lambda$, $\mu$. If we suppose this change to have been introduced, and still denote the independent variable by $y$, the equation has the form $y''+y'\Sigma(1-\lambda_i)/(x-\xi_i)+y(x,1)_{m-2}/\phi(x)=0$, while $\lambda+\mu+\lambda_1+\cdot\cdot\ \lambda_m=m-1$. Conversely, it is easy to verify that if $\lambda\mu$ be the coefficient of $x^{m-2}$ in $(x, 1)_{m-2}$, this equation has the specified singular points and indices whatever be the other coefficients in $(x, 1)_{m-2}$.

***Hypergeometric equation.***

Thus we see that (beside the cases $m=0$, $m=1$) the "Fuchsian equation" of the second order with *two* finite singular points is distinguished by the fact that it has a definite form when the singular points and the indices are assigned. In that case, putting $(x-\xi_1)/(x-\xi_2)=t/(t-1)$, the singular points are transformed to 0, 1, $\infty$, and, as is clear, without change of indices. Still denoting the independent variable by $x$, the equation then has the form $x(1-x)y''+y'[1-\lambda_1-x(1+\lambda+\mu)]-\lambda\mu y=0$, which is the ordinary hypergeometric equation. Provided none of $\lambda_1$, $\lambda_2$, $\lambda-\mu$ be zero or integral, it has the solutions $F(\lambda, \mu, 1-\lambda_1, x)$, $x^{\lambda_1}F(\lambda+\lambda_1, \mu+\lambda_1, 1+\lambda_1, x)$ about $x=0$; about $x=1$ it has the solutions $F(\lambda, \mu, 1-\lambda_2, 1-x)$, $(1-x)^{\lambda_2}F(\lambda+\lambda_2, \mu+\lambda_2, 1+\lambda_2, 1-x)$, where $\lambda+\mu+\lambda_1+\lambda_2=1$; about $x=\infty$ it has the solutions $x^{-\lambda}F(\lambda, \lambda+\lambda_1, \lambda-\mu+1, x^{-1})$, $x^{-\mu}F(\mu, \mu+\lambda_1, \mu-\lambda+1, x^{-1})$, where $F(\alpha\beta\gamma x)$ is the series $1+\alpha\beta x/\gamma+\dfrac{\alpha(\alpha+1)\beta(\beta+1)x^2}{1.2.\gamma(\gamma+1)}\cdot\cdot\cdot$, which converges when $|x|<1$, whatever $\alpha, \beta, \gamma$ may be, converges for all values of $x$ for which $|x|=1$ provided the real part of $\gamma-\alpha-\beta>0$ algebraically, and converges for all these values except $x=1$ provided the real part of $\gamma-\alpha-\beta>-1$ algebraically. In accordance with our general theory, logarithms are to be expected in the solution when one of $\lambda_1$, $\lambda_2$, $\lambda-\mu$ is zero or integral. Indeed when $\lambda_1$ is a negative integer, not zero, the second solution about $x=0$ would contain vanishing factors in the denominators of its coefficients; in case $\lambda$ or $\mu$ be one of the positive integers $1, 2, \cdot\cdot(-\lambda_1)$, vanishing factors occur also in the numerators; and then, in fact, the second solution about $x=0$ becomes $x^{\lambda_1}$ times an integral polynomial of degree $(-\lambda_1)-\lambda$ or of degree $(-\lambda_1)-\mu$. But when $\lambda_1$ is a negative integer including zero, and neither $\lambda$ nor $\mu$ is one of the positive integers $1, 2\cdot\cdot(-\lambda_1)$, the second solution about $x=0$ involves a term having the factor $\log x$. When $\lambda_1$ is a positive integer, not zero, the second solution about $x=0$ persists as a solution, in accordance with the order of arrangement of the roots of the index equation in our theory; the first solution is then replaced by an integral polynomial of degree $-\lambda$ or $-\mu$, when $\lambda$ or $\mu$ is one of the negative integers $0, -1, -2, \cdot\cdot\cdot, 1-\lambda_1$, but otherwise contains a logarithm. Similarly for the solutions about $x=1$ or $x=\infty$; it will be seen below how the results are deducible from those for $x=0$.

***March of the integral.***

Denote now the solutions about $x=0$ by $u_1, u_2$; those about $x=1$ by $v_1$, $v_2$; and those about $x=\infty$ by $w_1$, $w_2$; in the region $(S_oS_1)$ common to the circles $S_o$, $S_1$ of radius 1 whose centres are the points $x=0$, $x=1$, all the first four are valid, and there exist equations $u_1=Av_1+Bv_2$, $u_2=Cv_1+Dv_2$ where A, B, C, D are constants; in the region $(S_1S)$ lying inside the circle $S_1$ and outside the circle $S_o$, those that are valid are $v_1v_2w_1w_2$, and there exist equations $v_1=Pw_1+Qw_2$, $v_2=Rw_1+Tw_2$, where P, Q, R, T are constants; thus considering any integral whose expression within the circle $S_o$ is $au_1+bu_2$, where $a$, $b$ are constants, the same integral will be represented within the circle $S_1$ by $(aA+bC)v_1+(aB+bD)v_2$, and outside these circles will be represented by $[(aA+bC)P+(aB+bD)R]w_1+[(aA+bC)Q+(aB+bD)T]w_2$. A single-valued branch of such integral can be obtained by making a barrier in the plane joining $\infty$ to 0 and 1 to $\infty$; for instance, by excluding the consideration of real negative values of $x$ and of real positive values greater than 1, and defining the phase of $x$ and $x-1$ for real values between 0 and 1 as respectively 0 and $\pi$.

***Transformation of the equation into itself.***

We can form the Fuchsian equation of the second order with three arbitrary singular points $\xi_1$, $\xi_2$, $\xi_3$, and no singular point at $x=\infty$, and with respective indices $\alpha_1\beta_1\alpha_2\beta_2\alpha_3\beta_3$ such that $\alpha_1+\beta_1+\alpha_2+\beta_2+\alpha_3+\beta_3=1$. This equation can then be transformed into the hypergeometric equation in 24 ways; for out of $\xi_1$, $\xi_2$, $\xi_3$ we can in six ways choose two, say $\xi_1$, $\xi_2$, which are to be transformed respectively into 0 and 1, by $(x-\xi_1)/(x-\xi_2)=t/(t-1)$; and then there are four possible transformations of the dependent variable which will reduce one of the indices at $t=0$ to zero and one of the indices at $t=1$ also to zero, namely, we may reduce either $\alpha_1$ or $\beta_1$ at $t=0$, and simultaneously either $\alpha_2$ or $\beta_2$ at $t=1$. Thus the hypergeometric equation itself can be transformed into itself in 24 ways, and from the expression $F(\lambda, \mu, 1-\lambda_1, x)$ which satisfies it follow 23 other forms of solution; they involve four series in each of the arguments, $x, x-1, \dfrac{1}{x}, \dfrac{1}{1-x}, \dfrac{x-1}{x}, \dfrac{x}{x-1}$. Five of the 23 solutions agree with the fundamental solutions already described about $x=0$, $x=1$, $x=\infty$; and from the principles by which these were obtained it is immediately clear that the 24 forms are, in value, equal in fours.

***Inversion. Modular functions.***

The quarter periods K, K′ of Jacobi's theory of elliptic functions, of which $K=\int_0^{\frac{\pi}{2}}(1-h\ \sin^2\theta)^{-\frac{1}{2}}d\theta$, and K′ is the same function of $1-h$, can easily be proved to be the solutions of a hypergeometric equation of which $h$ is the independent variable. When K, K′ are regarded as defined in terms of $h$ by the differential equation, the ratio K′/K is an infinitely many valued function of $h$. But it is remarkable that Jacobi's own theory of theta functions leads to an expression for $h$ in terms of K′/K [see art. FUNCTIONS, ANALYTIC] in terms of single-valued functions. We may then attempt to investigate, in general, in what cases the independent variable $x$ of a hypergeometric equation is a single-valued function of the ratio $s$ of two independent integrals of the equation. The same inquiry is suggested by the problem of ascertaining in what cases the hypergeometric series $F(\alpha\beta\gamma x)$ is the expansion of an algebraic (irrational) function of $x$. In order to explain the meaning of the question, suppose that the plane of $x$ is divided along the real axis from $-\infty$ to 0 and from 1 to $+\infty$, and, supposing logarithms not to enter about $x=0$, choose two quite definite integrals $y_1, y_2$ of the equation, say $y_1=F(\lambda\mu 1-\lambda_1 x)$, $y_2=x^{\lambda_1}F(\lambda+\lambda_1, \mu+\lambda_1, 1+\lambda_1, x)$, with the condition that the phase of $x$ is zero when $x$ is real and between 0 and 1. Then the value of $s=\dfrac{y_2}{y_1}$ is definite for all values of $x$ in the divided plane, $s$ being a single-valued monogenic branch of an analytical function existing and without singularities all over this region. If, now, the values of $s$ that so arise be plotted on to another plane, a value $p+iq$ of $s$ being represented by a point $(p, q)$ of this $s$-plane, and the value of $x$ from which it arose being mentally associated with this point of the $s$-plane, these points will fill a connected region therein, with a continuous boundary formed of four portions corresponding to the two sides of the two barriers of the $x$-plane. The question is then, firstly, whether the same value of $s$ can arise for two different values of $x$, that is, whether the same point $(p, q)$ of the $s$-plane can arise twice, or in other words, whether the region of the $s$-plane overlaps itself or not. Supposing this is not so, a second part of the question presents itself. If in the $x$-plane the barrier joining $-\infty$ to 0 be momentarily removed, and $x$ describe a small circle with centre at $x=0$ starting from a point $x=-h-ik$, where $h, k$ are small, real, and positive and coming back to this point, the original value $s$ at this point will be changed to a value $\sigma$, which in the original case did not arise for this value of $x$, and possibly not at all. If, now, after restoring the barrier, the values arising by continuation from $\sigma$ be similarly plotted on the $s$-plane, we shall again obtain a region which, while not overlapping itself, may quite possibly overlap the former region. In that case two values of $x$ would arise for the same value or values of the quotient $y_2/y_1$, arising from two different branches of this quotient. We shall understand then, by the condition that $x$ is to be a single-valued function of $x$, that the region in the $s$-plane corresponding to any branch is not to overlap itself, and that no two of the regions corresponding to the different branches are to overlap. Now in describing the circle about $x=0$ from $x=-h-ik$ to $-h+ik$, where $h$ is small and $k$ evanescent, $s=x^{\lambda_1}F(\lambda+\lambda_1, \mu+\lambda_1, 1+\lambda_1, x)/F(\lambda, \mu, 1-\lambda_1, x)$ is changed to $\sigma=se^{2\pi i\lambda_1}$. Thus the two portions of

boundary of the $s$-region corresponding to the two sides of the barrier $(-\infty, 0)$ meet (at $s=0$ if the real part of $\lambda_1$ be positive) at an angle $2\pi L_1$, where $L_1$ is the absolute value of the real part of $\lambda_1$; the same is true for the $\sigma$-region representing the branch $\sigma$. The condition that the $s$-region shall not overlap itself requires, then, $L_1 \overline{\gtrless} 1$. But, further, we may form an infinite number of branches $\sigma = se^{2\pi i\lambda_1}$, $\sigma_1 = \sigma e^{2\pi i\lambda_1}$, $\cdots$ in the same way, and the corresponding regions in the plane upon which $y_2/y_1$ is represented will have a common point and each have an angle $2\pi L_1$; if neither overlaps the preceding, it will happen, if $L_1$ is not zero, that at length one is reached overlapping the first, unless for some positive integer $a$ we have $2\pi a L_1 = 2\pi$, in other words $L_1 = 1/a$. If this be so, the branch $\sigma_{a-1} = se^{2\pi i a\lambda_1}$ will be represented by a region having the angle at the common point common with the region for the branch $s$; but not altogether coinciding with this last region unless $\lambda_1$ be real, and therefore $=\pm 1/a$; then there is only a finite number, $a$, of branches obtainable in this way by crossing the barrier $(-\infty, 0)$. In precisely the same way, if we had begun by taking the quotient $s' = (x-1)^{\lambda_2} F(\lambda+\lambda_2, \mu+\lambda_2, 1+\lambda_2, 1-x)/F(\lambda, \mu, 1-\lambda_2, 1-x)$ of the two solutions about $x=1$, we should have found that $x$ is not a single-valued function of $s'$ unless $\lambda_2$ is the inverse of an integer, or is zero; as $s'$ is of the form $(As+B)/(Cs+D)$, A, B, C, D constants, the same is true in our case; equally, by considering the integrals about $x=\infty$ we find, as a third condition necessary in order that $x$ may be a single-valued function of $s$, that $\lambda-\mu$ must be the inverse of an integer or be zero. These three differences of the indices, namely, $\lambda_1, \lambda_2, \lambda-\mu$, are the quantities which enter in the differential equation satisfied by $x$ as a function of $s$, which is easily found to be $-\dfrac{x_{111}}{x_1^3} + \dfrac{3}{2}\dfrac{x_{11}^2}{x_1^4} = \frac{1}{2}(h-h_1-h_2)x^{-1}(x-1)^{-1} + \frac{1}{2}h_1 x^{-2} + \frac{1}{2}h_2(x-1)^{-2}$, where $x_1 = dx/ds$, etc.; and $h_1 = 1-\lambda_1^2$, $h_2 = 1-\lambda_2^2$, $h_3 = 1-(\lambda-\mu)^2$. Into the converse question whether the three conditions are sufficient to ensure (1) that the $s$ region corresponding to any branch does not overlap itself, (2) that no two such regions overlap, we have no space to enter. The second question clearly requires the inquiry whether the group (that is, the monodromy group) of the differential equation is properly discontinuous. (See art. GROUPS.)

The foregoing brief account will give an idea of the nature of the function theories of differential equations; it appears essential not to exclude some explanation of a theory intimately related both to such theories and to transformation theories, which is a generalization of Galois's theory of algebraic equations. We deal only with the application to homogeneous linear differential equations.

**Rationality group of a linear equation.**

In general a function of variables $x_1, x_2, \cdots$ is said to be rational when it can be formed from them and the integers 1, 2, 3 $\cdots$ by a finite number of additions, subtractions, multiplications, and divisions. We generalize this definition. Assume that we have assigned a fundamental series of quantities and functions of $x$, in which $x$ itself is included, such that all quantities formed by a finite number of additions, subtractions, multiplications, divisions, and differentiations in regard to $x$, of the terms of this series, are themselves members of this series. Then the quantities of this series, and only these, are called *rational*. And by a rational function of quantities $p, q, r \cdots$ is meant a function formed from them and any of the fundamental rational quantities by a finite number of the five fundamental operations. Thus it is a function which would be called, simply, rational if the fundamental series were widened by the addition to it of the quantities $p, q, r \cdots$ and those derivable from them by the five fundamental operations. A rational ordinary differential equation, with $x$ as independent and $y$ as dependent variable, is then one which equates to zero a rational function of $y$, the order $k$ of the differential equation being that of the highest differential coefficient $y^{(k)}$ which enters; only such equations are here discussed.

**Irreducibility of a rational equation.**

And such an equation $P=0$ is called *irreducible* when, firstly, being arranged as an integral polynomial in $y^{(k)}$, this polynomial is not the product of other polynomials in $y^{(k)}$ also of rational form; and, secondly the equation has no solution satisfying also a rational equation of lower order. From this it follows that if an irreducible equation $P=0$ have one solution satisfying another rational equation $Q=0$ of the same or higher order, then all the solutions of $P=0$ also satisfy $Q=0$. For from the equation $P=0$ we can by differentiation express $y^{(k+1)}, y^{(k+2)} \cdots$ in terms of $x, y, y^{(1)}, \cdots, y^{(k)}$, and so put the function Q rationally in terms of these quantities only. It is sufficient, then, to prove the result when the equation $Q=0$ is of the same order as $P=0$. Let both the equations be arranged as integral polynomials in $y^{(k)}$; their algebraic eliminant in regard to $y^{(k)}$ must then vanish identically, for they are known to have one common solution not satisfying an equation of lower order; thus the equation $P=0$ involves $Q=0$ for all solutions of $P=0$.

**The variant function for a linear equation.**

Now let $y^{(n)} = a_1 y^{(n-1)} + \cdots + a_n y$ be a given rational homogeneous linear differential equation; let $y_1 \cdots y_n$ be $n$ particular functions of $x$, unconnected by any equation with constant coefficients of the form $c_1 y_1 + \cdots + c_n y_n = 0$, all satisfying the differential equation; let $\eta_1 \cdots \eta_n$ be linear functions of $y_1 \cdots y_n$, say $\eta_i = A_{i1} y_1 + \cdots + A_{in} y_n$, where the constant coefficients $A_{ij}$ have a non-vanishing determinant; write $(\eta) = A(y)$, these being the equations of a general linear homogeneous group whose transformations may be denoted by A, B, $\cdots$. We desire to form a rational function $\phi(\eta)$, or say $\phi(A(y))$, of $\eta_1 \cdots \eta_n$, in which the $n^2$ constants $A_{ij}$ shall all be essential, and not reduce effectively to a fewer number, as they would, for instance, if the $y_1 \,.\,.\, y_n$ were connected by a linear equation with constant coefficients. Such a function is in fact given, if the solutions $y_1 \cdot y_n$ be developable in positive integral powers about $x=a$, by $\phi(\eta) = \eta_1 + (x-a)^n \eta_2 + \cdots + (x-a)^{(n-1)n} \eta_n$. Such a function, V, we call a *variant*.

**The resolvent equation.**

Then differentiating V in regard to $x$, and replacing $\eta_i^{(n)}$ by its value $a_1 \eta^{(n-1)} + \cdots + a_n \eta$, we can arrange $dV/dx$, and similarly each of $d^2V/dx^2 \cdots d^N V/dx^N$, where $N=n^2$, as a linear function of the N quantities $\eta_1 \cdots \eta_n \cdots \eta_1^{(n-1)} \cdots \eta_n^{(n-1)}$, and thence by elimination obtain a linear differential equation for V of order N with rational coefficients. This we denote by $F=0$. Further, each of $\eta_1 \cdots \eta_n$ is expressible as a linear function of V, $dV/dx \cdots d^{N-1}V/dx^{N-1}$, with rational coefficients not involving any of the $n^2$ coefficients $A_{ij}$, since otherwise V would satisfy a linear equation of order less than N, which is impossible, as it involves (linearly) the $n^2$ arbitrary coefficients $A_{ij}$, which would not enter into the coefficients of the supposed equation. In particular, $y_1 \cdots y_n$ are expressible rationally as linear functions of $\omega$, $d\omega/dx$, $\cdots d^{N-1}\omega/dx^{N-1}$, where $\omega$ is the particular function $\phi(y)$. Any solution W of the equation $F=0$ is derivable from functions $\zeta_1 \cdots \zeta_n$, which are linear functions of $y_1 \cdots y_n$, just as V was derived from $\eta_1 \cdots \eta_n$; but it does not follow that these functions $\zeta_1 \cdots \zeta_n$ are obtained from $y_1 \cdots y_n$ by a transformation of the linear group A, B, $\cdots$; for it may happen that the determinant $d(\zeta_1 \cdots \zeta_n)/d(y_1 \cdots y_n)$ is zero. In that case $\zeta_1 \cdots \zeta_n$ may be called a singular set, and W a singular solution; it satisfies an equation of lower than the N-th order. But every solution V, W, ordinary or singular, of the equation $F=0$, is expressible rationally in terms of $\omega$, $d\omega/dx$, $\cdots d^{N-1}\omega/dx^{N-1}$; we shall write, simply, $V = r(\omega)$. Consider now the rational irreducible equation of lowest order, not necessarily a linear equation, which is satisfied by $\omega$; as $y_1 \cdots y_n$ are particular functions, it may quite well be of order less than N; we call it the *resolvent equation*, suppose it of order $p$, and denote it by $\gamma(v)$. Upon it the whole theory turns. In the first place, as $\gamma(v)=0$ is satisfied by the solution $\omega$ of $F=0$, all the solutions of $\gamma(v)$ are solutions $F=0$, and are therefore rationally expressible by $\omega$; any one may then be denoted by $r(\omega)$. If this solution of $F=0$ be not singular, it corresponds to a transformation A of the linear group (A, B, $\cdots$), effected upon $y_1 \cdots y_n$. The coefficients $A_{ij}$ of this transformation follow from the expressions before mentioned for $\eta_1 \cdots \eta_n$ in terms of V, $dV/dx$, $d^2V/dx^2$, $\cdots$ by substituting $V = r(\omega)$; thus they depend on the $p$ arbitrary parameters which enter into the general expression for the integral of the equation $\gamma(v)=0$. Without going into further details, it is then clear enough that the resolvent equation, being irreducible and such that any solution is expressible rationally, with $p$ parameters, in terms of the solution $\omega$, enables us to define a linear homogeneous group of transformations of $y_1 \cdots y_n$ depending on $p$ parameters; and every operation of this (continuous) group corresponds to a rational transformation of the solution of the resolvent equation. This is the group called the *rationality group*, or the *group of transformations* of the original homogeneous linear differential equation.

The group must not be confounded with a subgroup of itself, the *monodromy group* of the equation, often called simply the group of the equation, which is a set of transformations, not depending on arbitrary variable parameters, arising for one particular fundamental set of solutions of the linear equation (see art. GROUPS).

**The fundamental theorem in regard to the rationality group.**

The importance of the rationality group consists in three propositions. (1) Any rational function of $y_1 \cdots y_n$ which is unaltered in value by the transformations of the group can be written in rational form. (2) If any rational function be changed in form, becoming a rational function of $y_1 \cdots y_n$, a transformation of the group applied to its new form will leave its value unaltered. (3) Any homogeneous linear transformation leaving unaltered the value of every rational function of $y_1 \cdots y_n$ which has a rational value, belongs to the group. It follows from these that any group of linear homogeneous transformations having the properties (1) (2) is identical with the group in question. It is clear that with these properties the group must be of the greatest

importance in attempting to discover what functions of $x$ must be regarded as rational in order that the values of $y_1 \cdot \cdot y_n$ may be expressed. And this is the problem of solving the equation from another point of view.

**Diffraction Gratings.**—The grating is an optical instrument for the production of the spectrum; it now generally replaces the prism in a spectroscope where large dispersion is needed, or when the ultra-violet portion of the spectrum is to be examined, or when the spectrum is to be photographed. The transparent grating consists of a plate of glass covered with lampblack, gold leaf, opaque collodion or gelatine, the coating being scratched through in parallel lines ruled as nearly equidistant as possible. When the lines are to be ruled very close together, a diamond ruling directly on glass is used. Other transparent materials, such as fluor-spar, are sometimes substituted for glass. For certain researches on long waves the grating is made by winding a very fine wire, 1-1000th inch in diameter, in the threads of two fine screws placed parallel to each other, soldering the wire to the screws and then cutting it away on one side of the screws. As the value of a grating is dependent upon the number of lines ruled, it is very desirable to have their number great. Glass is so hard that the diamond employed for the ruling wears away rapidly; and hence the modern grating is generally a reflecting grating, which is made by ruling on a speculum metal surface finely ground and polished. On such a surface it is possible to rule 100,000 lines without damaging the diamond, although its point even then often wears away or breaks down. The lines are generally so close together as 15,000 or 20,000 to the inch, although it is feasible to rule them even closer—say 40,000 to 50,000 to the inch There is little advantage, however, in the higher number, and many disadvantages.

The grating produces a variety of spectra from a single source of light, and these are designated as spectra of the first, second, &c., order, the numbering commencing from the central or reflected image and proceeding in either direction from it. The dispersion depends upon the number of lines ruled in a unit of length, upon the order of the spectrum, and upon the angle at which the grating is held to the source of light. The defining power depends upon its width and the angles made by the incident and diffracted rays, and is independent of the number of lines per unit of length ruled on the grating. If this number is too small, however, the different order of the spectra will be too much mixed up with each other for easy vision. A convenient number is 15,000 to 20,000 lines to the inch, or from 6000 to 8000 to the centimetre. The defining power is defined as the ratio of the wave-length to the distance apart of the two spectral lines which can be just seen separate in the instrument. Thus the sodium or D lines have wave-lengths which differ from each other by ·597 $\mu\mu$, and their average wave-length is 589·3 $\mu\mu$. A spectroscope to divide them would thus require a defining power of 988. The most powerful gratings have defining powers from 100,000 to 200,000. Lord Rayleigh's formula for the defining power is

$$D = Nn,$$

where D is the defining power, N is the order of the spectrum, and $n$ is the total number of lines ruled on the grating. As the defining power increases with N, and since we can observe in a higher order as the number of lines ruled in a unit of length decreases, it is best to express the defining power in terms of the width of the grating, $w$. In this case we have for the maximum defining power $D' = 20{,}000\ w$ for small gratings, or $D' = 15{,}000\ w$ for extra fine large gratings, $w$ being the width of the gratings in centimetres. It is seldom that very large gratings are perfect enough to have a defining power of more than 10,000 $w$, owing to imperfection of surface or ruling. The relative brightness of the different orders of

spectra depend upon the shape of the groove as ruled by the diamond. No two gratings are ever alike in this respect, but exhibit an infinite variety of distributions of brightness. Copies of glass gratings can be made by

photography, contact prints being taken on collodio-chloride of silver or other dry plates. Reflecting gratings can be copied by pouring collodion or gelatine over the grating and stripping off the films thus formed. The latter warp, however, and destroy the definition to a great extent. The grating always produces a brighter spectrum in the violet than a prism. In the green the reflecting speculum metal grating may be brighter than a prism spectroscope of five prisms, and for higher dispersion it surpasses the prism spectroscope both in definition and brightness in all portions of the spectrum.

To produce the pure spectrum from flat gratings, two telescopes are generally used, as in Fig. 1.

The telescopes are fixed, and the grating is turned on its axis to pass to different portions of the spectrum. As the glass of the telescopes absorbs the ultra-violet light, this portion of the spectrum is cut off entirely, unless quartz lenses are used. The concave grating avoids this trouble, and produces a spectrum without the aid of lenses, the lines being ruled on a concave surface instead of on a flat one. Such a grating, properly mounted, produces what has been called a normal spectrum, and is specially adapted to photographic purposes (Fig. 2).

A special form of grating of great defining power has

been invented by Professor Michelson of the University of Chicago, called the "echelon" spectroscope (see Spectroscopy). It is, however, of very limited application.

See an article on "Gratings in Theory and Practice" in *Astronomy and Astro-Physics*, 1893, xii. p. 129. (H. A. R.)

**Diffusion of Gases.**—When two gases are contained in different parts of the same vessel, at the same pressure and temperature without any currents being set up between them, a gradual mixing takes place which is called *diffusion*. Diffusion may also occur if the gases are separated by a thin membrane; it is then usually called osmosis or transpiration, and may give rise to differences of pressure on the two sides of the membrane. In the diffusion now considered such differences would cause the gas as a whole to move from the region of higher to that of lower pressure, hence the pressure of the mixture must be the same everywhere. By Dalton's law, the pressure of a mixture of two gases is the sum of the partial pressures of the components, or, in other words, the sum of the pressures which each would exert separately. The sum of the partial pressures of the two gases is thus uniform. If then one gas is moving by diffusion in one direction, say from A to B, its partial pressure will be decreasing at A and increasing at B. Hence the partial pressure of the second gas must be increasing at A and decreasing at B,—that is, it must be moving from B to A. Thus diffusion may be regarded as consisting of two streams of gas flowing in opposite directions.

Now it is natural to assume (at any rate as an approximation) that the rate of flow of either gas is proportional to the rate at which its partial pressure decreases in the direction of flow, or, as engineers term it, to the "pressure gradient" in this direction. This again is proportional to the rate of decrease of the density of the component in the same direction. We may define the *coefficient of diffusion* as the ratio of the total mass of either component which flows across a unit surface per unit time to the rate at which the density of that component decreases in a direction perpendicular to the said unit surface.

The equations of diffusion given in Clerk Maxwell's article Diffusion (*Ency. Brit.* 9th ed., vii. 216) need not be repeated here. According, however, to Meyer, Tait, and others, the coefficient of diffusion depends in general on the proportion of the two components contained in the mixture, and thus varies from point to point. The diffusion equation then becomes $dv_1/dt = (d/dx)(\mathrm{D}dv_1/dx)$, an integral of which has been found by Boltzmann. The equation of diffusion when gravity is taken into account has been integrated by Des Coudres.

Natanson has reduced diffusion and other irreversible phenomena to particular cases of a general principle which he calls the "thermokinetic principle," and which includes as a particular case the principle of least action of reversible dynamics. The "dissipation function," or expression for the rate at which heat is dissipated by diffusion is calculated, and from it are deduced equations similar to those in Maxwell's article.

***Kinetic theory.***

The discovery by Lord Rayleigh of an unpublished memoir "On the Physics of Media that are composed of free and perfectly elastic Molecules in a State of Motion," which paper had been deposited in the archives of the Royal Society, shows that much of the kinetic theory of gases, including the view that the temperature of a gas is proportional to the square of the molecular velocity, was first established by J. J. Waterston in 1845. The kinetic theory, in its general aspect, is supported by modern experiments in high vacua. In many of Dewar's experiments with liquid air a glass bulb placed in a mercury vacuum becomes coated with mercury in a surprisingly short time. The rate of deposition agrees fairly well with the formula for the total mass of molecules falling on a unit of area per unit time, viz., $\frac{1}{4}\rho q$ where $\rho$ = density, $q$ = mean molecular velocity. Sir William Crookes's observation, that if two unequally exhausted vacuum tubes are connected by a fine capillary tube, equalization of pressure takes place very slowly, accords with what we should naturally expect in a rarefied gas consisting of molecules moving in straight lines, and rebounding from the sides of the vessels with but rare collisions with each other; for the molecules would rarely chance to strike on the opening of the tube. The cathode rays have been attributed to a stream of molecules or particles projected by the cathode, and the fact that they only exist in high vacua accords with the view that at ordinary pressures the molecules of gas would collide with and obstruct them. In 1899 J. J. Thomson demonstrated the existence of such particles ("corpuscles" or "electrons") having masses much smaller than those of atoms; a similar conclusion was arrived at in connexion with the Becquerel rays by M. and Mme. Curie.

The presence of certain gases in the atmospheres of some planets and their absence from others admits in some cases of a ready explanation according to the kinetic theory, to which may be attributed in particular the absence of atmosphere from the moon. Those molecules which are moving away from a planet with velocity greater than that due to the planet's attraction tend to escape from the planet's atmosphere. Hence we should expect

the smaller planets to retain only the denser gases whose molecular velocity at a given temperature is least. Yet the present writer's calculations indicate that the molecular velocities assigned by the kinetic theory are insufficient in themselves to remove helium from our atmosphere, a point discussed by Stoney in 1897 and 1900. Very similar in principle is the explanation of *dissociation*. If we assume the molecules of a compound gas to be made up of atoms which are bound together by their mutual attraction, and adopt Boltzmann's hypothesis that the heat-energy of a molecule is due partly to translation and partly to rotation, it is evident that with increase of temperature there will be an increasing number of molecules, in which the "centrifugal force" due to rotation exceeds the force of attraction between the atoms, causing these atoms to break asunder. The kinetic theory of dissociation is treated at some length in Boltzmann's book.

**Boltzmann-Maxwell distribution.**

The distribution of velocity among the molecules of a gas, worked out by Watson and Burbury in their article MOLECULE (*Ency. Brit.*, 9th ed., xvi. 612), is called the Boltzmann-Maxwell distribution, and when it exists the gas is said by Tait to be in the "special state." There is abundant evidence that this distribution holds good in any gas in which (*a*) the actions between the molecules resemble the collisions of elastic bodies; (*b*) the sum of the volumes of the individual molecules is very small compared with the volume of the gas.

Much doubt still exists as to how far the distribution is applicable to gases whose molecules are of appreciable volume, or repel one another with finite forces which are functions of the distances between them. Burbury is of opinion that in such cases the motions of the molecules tend to become *correlated*, by which he means that two neighbouring molecules are more likely to move in the same than in opposite directions. For monatomic molecules (material particles or smooth spheres), he finds that the probability of the velocity components $(u_1,v_1,w_1)$, $(u_2,v_2,w_2)$... lying within the limits of the multiple differential $du_1dv_1dw_1 \cdot du_2dv_2dw_2$... is proportional to $e^{-hQ}$, where

$$Q = \tfrac{1}{2}\Sigma m(u_1^2+v_1^2+w_1^2) + \Sigma\Sigma b_{12}(u_1u_2+v_1v_2+w_1w_2)$$

$b_{12}$ being a negative function of the distance between the two molecules designated by the suffixes 1, 2, which is inappreciable except when this distance is small. The motion changes its character when Q ceases to be essentially positive, and this change may possibly be the condition for liquefaction. If the $b_{12}$ coefficients vanish we have the Boltzmann-Maxwell distribution.

The special case of the Boltzmann-Maxwell distribution for molecules regarded as non-spherical, elastic, rigid bodies, and capable of having angular velocities $\omega_1$, $\omega_2$, $\omega_3$ about their principal axis of inertia, besides translatory velocities $v$, $v$, $w$ of their centre of gravity, is interesting. The kinetic energy is given by

$$T = \tfrac{1}{2}m(u^2+v^2+w^2) + \tfrac{1}{2}(A\omega_1^2 + B\omega_2^2 + C\omega_3^2),$$

and the distribution being given by the expression

$$e^{-hT}\, du\, dv\, dw\, d\omega_1 d\omega_2 d\omega_3,$$

it follows that the mean values of $\frac{1}{2}mu^2$, $\frac{1}{2}mv^2$, $\frac{1}{2}mw^2$, $\frac{1}{2}A\omega_1^2$, $\frac{1}{2}B\omega_2^2$, $\frac{1}{2}C\omega_3^2$ are each equal to $1/h$. This is a particular case of a statement known as Maxwell's Law of Partition of Energy, according to which in certain cases, "if the kinetic energy of a system be expressed as a sum of squares, the mean values of these squares are equal." The applicability of this law to dynamical systems in general, and indeed to *any* systems other than groups of molecules arranged according to the Boltzmann-Maxwell distribution, has for many years been a source of controversy, and was discussed in 1900 by Lord Rayleigh. When $C=0$, or the molecule consists of a distribution of masses along a straight line, the energy is equally divided between the five remaining components; this gives a specific heat ratio of 1·4 approximating to that of most gases, while the specific heat ratio, on the hypothesis that the energy is wholly translational, is $1\frac{2}{3}$, or nearly that of argon. The tendency of the molecules of a gas to assume the Boltzmann-Maxwell distribution, if their velocities are initially distributed in any other manner, has been investigated by Boltzmann and Watson in a theorem known as Boltzmann's Minimum Theorem.

Let $fdv$ denote the probability that the co-ordinates and momenta of a molecule shall lie within the limits of the multiple differential $dv\,(=dp_1,...dq_n$ of Watson and Burbury's article MOLECULE). Let H denote the integral $\int\int \log fdv$, or for a mixture of gases let $H=\Sigma\int\int \log f dv$, the summation extending over the several components. Then it is proved in the Minimum Theorem that, as the result of intermolecular collisions or encounters, H tends to decrease until the "special state" is reached, when it becomes a minimum. This proposition is further shown by Boltzmann to admit of both mathematical and physical interpretations.

(1) According to the theory of probability, Boltzmann finds that if W is proportional to the probability that the distribution of co-ordinates and momenta may be defined by the function $f$, then log W is proportional to $-H$. Hence, as H decreases, W increases; in other words (*a*) the molecular motions tend to pass from less probable to more probable distributions, and (*b*) the Boltzmann-Maxwell distribution is the most probable of all distributions.

(2) The entropy of the gas is proportional to $-H+$ a constant, and the tendency of H to decrease to a minimum thus represents the physical property that the entropy of a system tends to increase to a maximum.

**Diffusion.**

When the molecules of a gas are thoroughly mixed (as assumed in the Minimum Theorem), it appears, from the calculations of Tait and Watson, that a very small fraction of a second is sufficient, in ordinary cases, to restore the molecules to the Boltzmann-Maxwell distribution. We now have to consider diffusion and allied phenomena in which the distribution, instead of being uniform, varies at different points of the gas. In such cases the process of equalization, which is comparatively slow, depends on the free paths of the molecules between collisions. We proceed to investigate the general problem by a method based on the work of Boltzmann and used subsequently by Burbury.

If a molecule A moving with velocity $w$ impinge normally on a stratum of gas of thickness $x$ containing $n$ molecules per unit volume, whose velocities are distributed about a mean velocity $q$, it is easy to see that, if $nx$ is small, the probability of its encountering another molecule in traversing the layer is proportional to $n\pi s^2x$, where $s$ is the sum of the radii of the impinging and interfering molecules when these are spherical, and $s$ is determined by the linear dimensions of the molecules in other cases. Since, moreover, the probability is evidently unaltered by increasing the velocities of the impinging and interfering molecules in the same ratio it may be written $n\pi s^2x\psi(w/q)$, where $\psi(w/q)$ is a function, calculated by Meyer, Tait, and others. If $nx$ is not small we divide the $nx$ molecules into a large number $r$ of equal groups, and the chance of A escaping collision is the *product* of its chances of escaping collision with the groups, and therefore

$$= \mathop{\mathrm{L}}_{r=\infty}\left\{1-\frac{nx\pi s^2}{r}\psi\left(\frac{w}{q}\right)\right\}^r = e^{-xn\pi s^2\psi(w/q)} = e^{-x/l} \text{ say.}$$

Here $l$ is the constant defined in the article MOLECULE (*Ency. Brit.* vol. xvi. p. 616). The *mean free path* may be found as in that article. Tait, on the other hand, defines the mean free path as the mean value of $l$, when the molecule A is replaced by a number of molecules in the "special state," and the value he finds for a simple gas is $0{\cdot}677/n\pi s^2$.

Now let G be any physical quantity (*e.g.*, mass, charge of electricity, momentum, energy, &c.) which may be carried by a molecule. Let the quantity of G per unit volume vary uniformly in the direction of the axis of $z$, and be denoted by $G(z)$; also let $f(w)dw$ denote the proportion of molecules whose translational speeds are between $w$ and $w+dw$. It is required to find the rate at which G is being carried across the plane $z=z_0$.

Now the total number of molecules crossing the plane $z_0$ in unit of time, and having their velocities between $w$ and $w+dw$, in directions at inclinations to the axis of $z$ between $\theta$ and $\theta+d\theta$ is

$$= \tfrac{1}{2}wf(w)\sin\theta\cos\theta\, d\theta\, dw.$$

The number of those that have travelled a distance between $\lambda$ and $\lambda+d\lambda$ since their last encounter is found by multiplying this number by $e^{-\lambda/l}d\lambda/l$. These molecules must have collided between the planes $z=z_0+\lambda\cos\theta$ and $z=z_0+(\lambda+d\lambda)\cos\theta$, and they are assumed to carry their average share of the quantity G between

these two planes, *i.e.*, $G(z_0+\lambda\cos\theta)$. Hence the total quantity of G carried across the plane $z=z_0$ in the negative direction is $\Gamma$, where

$$\Gamma=\int_0^\infty dw\int_0^\pi d\theta\int_0^\infty d\lambda\ wf(w)\ \tfrac{1}{2}\sin\theta\cos\theta\frac{e^{-\lambda/l}}{l}G(z_0+\lambda\cos\theta),$$

the integration between $\theta=0$ and $\theta=\frac{1}{2}\pi$ representing the part due to molecules coming from the positive side and between $\theta=\frac{1}{2}\pi$ and $\theta=\pi$, that due to molecules coming from the negative side. Making the assumption that G varies uniformly, or neglecting differential coefficients above the first, we obtain

$$G(z_0+\lambda\cos\theta)=G(z_0)+\lambda\cos\theta\frac{dG}{dz},$$

therefore

$$\Gamma=\frac{1}{3}\frac{dG}{dz}\int_0^\infty f(w)wl\,dw=\frac{1}{3}\overline{wl}\frac{dG}{dz}.$$

For the diffusion of two gases, A and B, in a mixture containing $N_a$ and $N_b$ molecules per unit volume of the two components, we put $G=N_a$ and $G=N_b$ in succession, and obtain

$$\Gamma_a=\frac{1}{3}\overline{wl_a}\frac{dN_a}{dz}\qquad\Gamma_b=\frac{1}{3}\overline{wl_b}\frac{dN_b}{dz}.$$

If $\overline{wl_a}$ and $\overline{wl_b}$ are unequal, $\Gamma_a$ and $\Gamma_b$ will be unequal. The formula gives more molecules flowing in one direction than in the other, and the pressure (which is proportional to $N_a+N_b$) would on this hypothesis soon cease to be uniform. Meyer assumes, therefore, that there is a counter current $\Gamma_b-\Gamma_a$, and, as in the article MOLECULE, the coefficient of diffusion becomes

$$\frac{1}{3}\frac{N_a\overline{wl_a}+N_b\overline{wl_b}}{N_a+N_b}.$$

If, however, we assume that the diffusion of the gas A is unaffected by its collisions with molecules of the same gas, and only depends on collisions with the B molecules, and similarly for the gas B, we get for the coefficient of diffusion

$$\frac{1}{3}\frac{\overline{wl_a}+\overline{wl_b}}{2}.$$

The last formula has been used by Stefan, but is objected to by Meyer. Both formulæ have been tested experimentally, but practical difficulties give rise to discrepancies in the observed results quite as great as the differences given by the formulæ. Where the gases are mixed in equal proportions the two formulæ become identical; and to decide between them it is necessary to examine diffusion in mixtures where one gas preponderates largely over the other. Such cases are, however, difficult of observation.

When the molecules are of the same size, shape, and mass $\overline{wl_a}=\overline{wl_b}$, and the coefficient of diffusion is $\frac{1}{3}\overline{wl}$ on either hypothesis. It is therefore everywhere constant.

***Tait's conclusions.***

Taking unequal spherical molecules, Tait, by evaluating the integrals depending on his form of $l$, arrives at the following conclusions:—(1) For molecules of equal mass, a difference of size, the mean of the diameters being unchanged, favours diffusion. (2) Diffusion is, however, but little affected by even a considerable disparity in size of the molecules, but depends mainly on the mean of the diameters. (3) Taking molecules of masses in the ratio 16 : 1, and of diameters in the ratios 3 : 1, 1 : 1, and 1 : 3, it is found that if the sum of the diameters is kept constant, diffusion is most rapid when the molecules of greater mass have the greater diameter. (4) A gas diffuses more quickly into one of different than into one of the same specific gravity. (5) If the diameters of the more massive molecules are decreased and of the lighter ones increased, keeping their sum constant, the rate of diffusion decreases to a minimum at first and then increases before the more massive molecules become infinitesimal compared with the others. (6) Owing to the smallness of the variations of the diffusion-coefficient, experiments on diffusion are not well suited for determining the relative size of the molecules of different gases.

***Viscosity and thermal conductivity.***

Next taking G to represent translational velocity in a plane perpendicular to the axis of $z$ and assuming it to be proportional to $z$, if the density be $\rho$, then $\rho\Gamma$ will represent the momentum carried across the plane $z=z_0$ per unit time, *i.e.*, the shearing force, and the coefficient of $dG/dz$ in $\rho\Gamma$ will be the *coefficient of viscosity*, which therefore $=\frac{1}{3}\rho\overline{wl}$.

In conduction of heat the mean translational energy T or $\frac{1}{2}m\overline{w^2}$ is a function of $z$. If $f(w)dw$ denote the proportion of molecules with speeds between $w$ and $w+dw$ at a point where this mean energy is $T_0$, $f(w)dw$ will at other points denote the proportion of molecules with speeds between $w\sqrt{(T/T_0)}$ and $(w+dw)\sqrt{(T/T_0)}$ We assume these molecules to carry with them translational energy $\frac{1}{2}mw^2T/T_0$, and rotational energy $\frac{1}{2}\beta m\overline{w^2}\ T/T_0$ where $\beta=2/(3k-3)-1$, and $k$ is the specific heat ratio. In calculating the true thermal conductivity we have to separate the transference of heat-energy due to conduction proper from that due to motion of the medium. By a method resembling Boltzmann's we find

$$\Gamma=\frac{1}{3T}\ \frac{dxT}{dz}\int\tfrac{1}{2}m(w^2+\beta\overline{w^2})wl\,dw=\frac{n}{3}\left\{\frac{\overline{w^3l}}{\overline{w^2}}+\beta\overline{wl}\right\}\frac{dT}{dz}.$$

Putting $\eta=\frac{1}{3}nm\overline{wl}$ we see that the thermal conductivity of a gas is proportional to its coefficient of viscosity $\eta$. The above, and other formulæ based on alternative assumptions, give in general for the conductivity an expression of the form

$$K=(Ak+B)\eta c_v,$$

$c_v$ being the specific heat at constant volume and A, B, con stants. Meyer finds $A=0{\cdot}795$, $B=0{\cdot}205$, giving for air at 0° C., $K=406.10^{-7}$ centigrade C.G.S. units. Boltzmann finds $A=\frac{75}{26}$, $B=-\frac{60}{26}$, giving $K=536.10^{-7}$. The values observed for air by Stefan and Winkelmann are $558.10^{-7}$ and $525.10^{-7}$ respectively. The thermal conductivity of gases is treated at considerable length by Verdet-Ruhlmann.

In the equation $\Gamma=\frac{1}{3}\overline{wl}\ dG/dz$ the coefficient of $dG/dz$, viz. $\frac{1}{3}\overline{wl}$, varies as the mean velocity $w$ and as the mean free path $l$. Now from the expression $n\pi s^2$ in the denominator of Tait's formula, or otherwise, we infer that for the same gas or mixture of gases $l$ varies inversely as $n$, and therefore directly as the volume. Hence on the hypothesis that the molecules are elastic bodies the coefficients of diffusion, viscosity, and conductivity vary as the volume and the square root of the absolute temperature. If the pressure $p$ and temperature T be taken as variables they will vary inversely as $p$ and directly as $T^{\frac{3}{2}}$. Now it appears from Maxwell's experiments that the coefficient of viscosity at constant density is proportional to T instead of $T^{\frac{1}{2}}$, and from Loschmidt's experiments it is not improbable that the coefficient of diffusion at constant pressure is proportional to $T^2$ instead of $T^{\frac{3}{2}}$. These considerations led Maxwell to consider a kinetic theory based on the hypothesis that the molecules of a gas repel one another with finite forces which are functions of the distance between them, and in particular to consider the case when the force varies inversely as the fifth power of the distance, in which case the viscosity varies as T. The phenomena of diffusion, viscosity, and conductivity and fluid motions, have been worked out on this hypothesis very fully by Boltzmann and others. The relation of the coefficient of diffusion to the temperature appears, however, difficult to determine experimentally. A "pressure balance" for this purpose has been described by M. Toepler.

**Dignano** (Slavonic, *Vodnjan*), a town in the government district of Pola, Istria (Austria), about 8 miles north of Pola, on the railway from Trieste. It is situated on a gentle slope overlooking the Gulf of Venice, a few miles from the shore. The principal resource of the inhabitants (in 1890, 9151; in 1900, 9684—mostly Italian) is the cultivation of the vine, olive, fruit, and the silkworm, together with a considerable trade in timber. The so-called rose-vine, one of the best of the Istrian varieties, is grown in the vicinity.

**Dijon,** chief town of department Côte-d'Or, France, 196 miles south-east of Paris, on railway from Paris to Lyon. It is the seat of a court of appeal for the departments of Côte d'Or, Haute Marne, and Seine-et-Loire, and has schools of medicine and pharmacy. Since the Franco-Prussian War it has been strongly fortified, and it is now protected by eight forts. The bathing establishment or casino was rebuilt in ornate style in 1886. The manufacture of heavy iron goods and machinery has become extensive, and there are large soap works, while black-currant liqueur ("cassis de Dijon") is a speciality; cotton-spinning is still carried on, but textile industries are no longer of any account. Population (1881), 46,344; (1891), 55,673; (1901), 70,428.

**Dillmann, Christian Friedrich August** (1823–1894), German theologian and Orientalist, was born at Illingen, Würtemberg, 25th April 1823. He commenced the study of theology at Tübingen, where he was a favourite pupil of Ewald, who encouraged him to pursue the study of the Oriental languages, of which, after having for some years been a *Privat-docent*, he became extraordinary professor in 1853. In 1854 he removed to Kiel, where he was made regular professor in 1860. Having, however, signalized himself as a divine as well as an Oriental scholar, he was in 1864 invited to fill the post of professor of biblical exegesis at Giessen, and in 1869 succeeded the celebrated Hengstenberg as exegetical professor at Berlin. His lectures were much esteemed, but his principal distinction was gained by his researches in the Ethiopic language and literature, upon which he was regarded as the highest living authority. Between 1846 and 1848, and before his first appointment at Tübingen, he visited France and England as a student, and while in England prepared the seventh volume of the Bodleian catalogue of manuscripts, comprising the Ethiopic. This catalogue was published in 1848. Dillmann also catalogued the Ethiopic MSS. in the British Museum. In 1851 he edited the apocryphal Book of Enoch in the Ethiopic version, the only one in which it is extant, and published an annotated translation of it in 1853. In the same year he translated the Ethiopic Book of Adam, and in 1855 edited the ancient Ethiopic translation of the Old Testament. He was also the author of an Ethiopic grammar (1857) and lexicon (1862–65), standard works in their department of philology. Among his Ethiopic labours may also be reckoned two works on the history of the kingdom of Axum, published in 1879 and 1880. His principal theological writings are *On the Origin of the Religion of the Old Testament* (1865) and *On the Political Activity of the Old Testament Prophets* (1868). His investigations are characterized by a prevailing spirit of moderation and sobriety. He died at Berlin, 4th July 1894, leaving the reputation not merely of a great Ethiopic scholar, but of the reviver of a branch of Oriental study which had fallen into neglect. (R. G.)

**Dilolo, Lake.** See CONGO.

**Dimensions of Units.**—Measurable entities of different kinds cannot be directly compared. Each one must be specified in terms of a unit of its own kind; a single number attached to this unit forms its measure. Thus if the unit of length be taken to be L centimetres, a line whose length is $l$ centimetres will be represented in relation to this unit by the number $l/\mathrm{L}$; while if the unit is increased [L] times, that is, if a new unit is adopted equal to [L] times the former one, the numerical measure of each length must in consequence be divided by [L]. Measurable entities are either fundamental or derived For example, velocity is of the latter kind, being based upon a combination of the fundamental entities length and time; a velocity may be defined, in the usual form of language expressive of a limiting value, as the rate at which the distance from some fixed mark is changing per unit time. The element of length is thus involved directly and the element of time inversely in the derived idea of velocity; the meaning of this statement being that when the unit of length is increased [L] times and the unit of time is increased [T] times, the numerical value of any given velocity, considered as specified in terms of the units of length and time, is diminished [L]/[T] times. In other words, these changes in the units of length and time involve change in the unit of velocity determined by them, such that it is increased [V] times where $[\mathrm{V}]=[\mathrm{L}][\mathrm{T}]^{-1}$. This relation is conveniently expressed by the statement that velocity is of $+1$ dimension in length and of $-1$ dimension in time. Again, acceleration of motion is defined as rate of increase of velocity per unit time; hence the change of the units of length and time will increase the corresponding or derived unit of acceleration [V]/[T] times, that is $[\mathrm{L}][\mathrm{T}]^{-2}$ times: this expression thus represents the dimensions (1 in length and $-2$ in time) of the derived entity acceleration in terms of its fundamental elements length and time. In the science of dynamics all entities are derived from the three fundamental ones, length, time, and mass; for example, the dimensions of force (P) are those of mass and acceleration jointly, so that in algebraic form $[\mathrm{P}]=[\mathrm{M}][\mathrm{L}][\mathrm{T}]^{-2}$. This restriction of the fundamental units to three is therefore applicable to

all departments of physical science that are reducible to pure dynamics.

The mode of transformation of a derived entity, as regards its numerical value, from one set of fundamental units of reference to another set, is exhibited in the simple illustrations above given. When the numerical values of the new units, expressed in terms of the former ones, are substituted for the symbols, in the expression for the dimensions of the entity under consideration, the number which results is the numerical value of the new unit of that entity in terms of the former unit: thus all numerical values of entities of this kind must be divided by this number, in order to transfer them from the former to the latter system of fundamental units.

As above stated, physical science reduces the phenomena of which it treats to the common denomination of the positions and movements of masses. Before the time of Gauss it was customary to use a statical measure of force, alongside the kinetic measure depending on the acceleration of motion that the force can produce in a given mass. Such a statical measure could be conveniently applied by the extension of a spring, which, however, has to be corrected for temperature, or by weighing against standard weights, which has to be corrected for locality. On the other hand, the kinetic measure is independent of local conditions, if only we have absolute scales of length and time at our disposal. It has been found to be indispensable, for simplicity and precision in physical science, to express the measure of force in one way; and statical forces are therefore now generally referred in theoretical discussions to the kinetic unit of measurement. In mechanical engineering the static unit has largely survived; but the increasing importance of electrical applications is introducing uniformity there also. In the science of electricity two different systems of units, the electrostatic and the electrodynamic, still to a large extent persist. The electrostatic system arose because in the development of the subject statics came before kinetics; but in the complete synthesis it is even now found convenient to express the various quantities in terms of the electrokinetic system alone.

The system of measurement now adopted as fundamental in physics takes the centimetre as unit of length, the gramme as unit of mass, and the second as unit of time. The choice of these units was in the first instance arbitrary and dictated by convenience; for some purposes subsidiary systems based on multiples of these units by certain powers of ten are found convenient. There are certain absolute entities in nature, such as the constant of gravitation, the velocity of light in free space, and the constants occurring in the expression giving the constitution of the radiation in an enclosure that corresponds to each temperature, which are the same for all kinds of matter; these might be utilized, if known with sufficient accuracy, to establish a system of units of an absolute or cosmical kind. The wave-length of a given spectral line might be utilized in the same manner, but that depends on recovering the kind of matter which produces the line.

In physical science the uniformities in the course of phenomena are elucidated by the discovery of permanent or intrinsic relations between the measurable properties of material systems. Each such relation is expressible as an equation connecting the numerical values of entities belonging to the system. Such an equation, representing as it does a relation between actual things, must remain true when the measurements are referred to a new set of fundamental units. Thus, for example, the kinematical equation $v^2 = nf^2l$, if $n$ is purely numerical, contradicts the necessary relations involved in the definitions of the entities velocity, acceleration, and length which occur in it. For on changing to a new set of units as above the equation should still hold; it, however, then becomes $v^2/[V]^2 = n \cdot f^2/[F]^2 \cdot l/[L]$. Hence on division there remains a dimensional relation $[V]^2 = [F]^2[L]$, which is in disagreement with the dimensions above determined of the derived units that are involved in it. The inference follows either that an equation such as that from which we started is a formal impossibility, or else that the factor $n$ which it contains is not a mere number, but represents $n$ times the unit of some derived quantity which ought to be specified in order to render the equation a complete statement of a physical relation. On the latter hypothesis the dimensions $[N]$ of this quantity are determined by the dimensional equation $[V]^2 = [N][F]^2[L]$ where, in terms of the fundamental units of length and time, $[V] = [L][T]^{-1}$, $[F] = [L][T]^{-2}$; whence by substitution it appears that $[N] = [L]^{-1}[T]^2$. Thus, instead of being merely numerical, $n$ must represent in the above formula the measure of some physical entity, which may be classified by the statement that it has the conjoint dimensions of time directly and of velocity inversely.

It often happens that simple comparison of the dimensions of the quantities which determine a physical system will lead to important knowledge as to the necessary relations that subsist between them. Thus in the case of a simple pendulum the period of oscillation $\tau$ can depend only on the angular amplitude $a$ of the swing, the mass $m$ of the bob considered as a point, and the length $l$ of the suspending fibre considered as without mass, and on the value of $g$ the acceleration due to gravity, which is the active force; that is, $\tau = f(a, m, l, g)$. The dimensions must be the same on both sides of this formula, for, when they are expressed in terms of the three independent dynamical quantities mass, length, and time, there must be complete identity between its two sides. Now the dimensions of $g$ are $[L][T]^{-2}$; and when the unit of length is altered, the numerical value of the period is unaltered, hence its expression must be restricted to the form $f(a, m, l/g)$. Moreover, as the period does not depend on the unit of mass, the form is further reduced to $f(a, l/g)$; and as it is of the dimensions $+1$ in time, it must be a multiple of $(l/g)^{\frac{1}{2}}$, and therefore of the form $\phi(a)\sqrt{(l/g)}$. Thus the period of oscillation has been determined by these considerations except as regards the manner in which it depends on the amplitude $a$ of the swing. When a process of this kind leads to a definite result, it will be one which makes the unknown quantity jointly proportional to various powers of the other quantities involved; it will therefore shorten the process if we assume such an expression for it in advance, and find whether it is possible to determine the exponents definitely and uniquely so as to obtain the correct dimensions. In the present example, assuming in this way the relation $\tau = \mathrm{A}a^p m^q l^r g^s$, where A is a pure numeric, we are led to the dimensional equation $[T] = [a]^p[M]^q[L]^r[LT^{-2}]^s$, showing that the law assumed would not persist when the fundamental units of length, mass, and time are altered, unless $q = 0$, $s = -\frac{1}{2}$, $r = \frac{1}{2}$; as an angle has no dimensions, being determined by its numerical ratio to the *invariable* angle forming four right angles, $p$ remains undetermined. This leads to the same result, $\tau = \phi(a)l^{+\frac{1}{2}}g^{-\frac{1}{2}}$, as before.

As illustrating the power and also the limitations of this method of dimensions, we may apply it (after Lord Rayleigh, *Roy. Soc. Proc.*, March 1900) to the laws of viscosity in gases. The dimensions of viscosity ($\mu$) are (force/area) ÷ (velocity/length), giving $[ML^{-1}T^{-1}]$ in terms of the fundamental units. Now, on the dynamical theory of gases viscosity must be a function of the mass $m$ of a molecule, the number $n$ of molecules per unit volume, their velocity of mean square $\bar{v}$, and their effective radius $a$; it can depend on nothing else. The equation of dimensions cannot supply more than *three* relations connecting these four possibilities of

variation, and so cannot here lead to a definite result without further knowledge of the physical circumstances. And we remark conversely, in passing, that wherever in a problem of physical dynamics we know that the quantity sought can depend on only three other quantities whose dynamical dimensions are known, it must vary as a simple power of each. The additional knowledge required, in order to enable us to proceed in a case like the present, must be of the form of such an equation of simple variation. In the present case it is involved in the new fact that in an actual gas the mean free path is very great compared with the effective molecular radius. On this account the mean free path is inversely as the number of molecules per unit volume; and therefore the coefficient of viscosity, being proportional to these two quantities jointly, is independent of either, so long as the other quantities defining the system remain unchanged. If the molecules are taken to be spheres which exert mutual action only during collision, we therefore assume

$$\mu \propto m^x \bar{v}^y a^z,$$

which requires that the equation of dimensions

$$[ML^{-1}T^{-1}] = [M]^x [LT^{-1}]^y [L]^z$$

must be satisfied. This gives $x=1$, $y=1$, $z=-2$. As the temperature is proportional to $m\bar{v}^2$, it follows that the viscosity is proportional to the square root of the mass of the molecule and the square root of the absolute temperature, and inversely proportional to the square of the effective molecular radius, being, as already seen, uninfluenced by change of density. If the atoms are taken to be Boscovichian points exerting mutual attractions, the effective diameter $a$ is not definite; but we can still proceed in cases where the law of mutual attraction is expressed by a simple formula of variation—that is, *provided* it is of type $km^2r^{-s}$ where $r$ is the distance between the two molecules. Then, noting that, as this is a force, the dimensions of $k$ must be $[M^{-1}L^{s+1}T^{-2}]$, we can assume

$$\mu \propto m^x \bar{v}^y k^w,$$

provided $$[ML^{-1}T^{-1}] = [M]^x [LT^{-1}]^y [M^{-1}L^{s+1}T^{-2}]^w,$$

which demands and is satisfied by

$$x - w = 1,\ y + 2w = 1,\ y + (s+1)w = -1,$$

so that $$w = -\frac{2}{s-1},\ y = \frac{s+3}{s-1},\ x = \frac{s-3}{s-1}.$$

Thus, on this supposition,

$$\mu \propto m^{\frac{s-9}{2s-2}} k^{-\frac{2}{s-1}} \theta^{\frac{s+3}{2s-2}}$$

where $\theta$ represents absolute temperature. (See DIFFUSION OF GASES.)

In electrical science two essentially distinct systems of measurement were arrived at according as the development began with the phenomena of electrostatics or those of electrokinetics. An electric charge appears as an entity having different dimensions in terms of the fundamental dynamical units, in the two cases: the ratio of these dimensions proves to be the dimensions of a velocity. It was found, first by W. Weber, by measuring the same charge by its static and its kinetic effects, that the ratio of the two units is a velocity sensibly identical with the velocity of light, so far as regards experiments conducted in space devoid of dense matter. The emergence of a definite absolute velocity such as this, out of a comparison of two different ways of approaching the same quantity, entitles us to assert that the two ways can be consolidated into a single dynamical theory only by some development in which this velocity comes to play an actual part. Thus the hypothesis of the mere existence of some complete dynamical theory was enough to show, in the stage which electrical science had reached under Gauss and Weber, that there is a definite physical velocity involved in and underlying electric phenomena, which it would have been hardly possible to imagine as other than a velocity of propagation of electrical effects of some kind. The time was thus ripe for the reconstruction of electric theory by Faraday and Maxwell.

The power of the method of dimensions in thus revealing general relations has its source in the hypothesis that, however complicated in appearance, the phenomena are really restricted within the narrow range of dependence on the three fundamental entities. The proposition is also therein involved, that if a changing physical system be compared with another system in which the scale is altered in different ratios as regards corresponding lengths, masses, and times, then if all quantities affecting the second system are altered from the corresponding quantities affecting the first in the ratios determined by their physical dimensions, the stage of progress of the second system will always correspond to that of the first; under this form the application of the principle, to determine the correlations of the dynamics of similar systems, originated with Newton (*Principia*, lib. ii. prop. 32). For example, in comparing the behaviour of an animal with that of another animal of the same build but on a smaller scale, we may take the mass per unit volume and the muscular force per unit sectional area to be the same for both; thus [L], [M], . . . being now ratios of corresponding quantities, we have $[ML^{-3}] = 1$ and $[ML^{-1}T^{-2}] = 1$, giving $[L] = [T]$; thus the larger animal effects movements of his limbs more slowly in simple proportion to his linear dimensions, while the velocity of movement is the same for both. But this is only on the hypothesis that the extraneous force of gravity does not intervene, for that force does not vary in the same manner as the muscular forces. The result has thus application only to a case like that of fishes in which gravity is equilibrated by the buoyancy of the water. The limbs of a land animal have mainly to support his weight, which varies as the cube of his linear dimensions, while the sectional areas of his muscles and bones vary only as the square thereof. Thus the diameters of his limbs should increase in a greater ratio than that of his body,—theoretically in the latter ratio raised to the power $\frac{3}{2}$, if other things were the same. An application of this principle, which has become indispensable in modern naval architecture, permits the prediction of the behaviour of a large ship from that of a small-scale model. The principle is also of very wide utility in unravelling the fundamental relations in definite physical problems of such complexity that complete treatment is beyond the present powers of mathematical analysis; it has been applied, for example, to the motions of systems involving viscous fluids, in elucidation of wind and waves, by Helmholtz (*Akad. Berlin*, 1873 and 1889), and in the electrodynamics of material atomic systems in motion by Lorentz and by Larmor. (J. L*.)

**Dinajpur,** a town (with a population in 1891 of 12,204) and district of British India, in the Rajshahi division of Northern Bengal. The earthquake of 12th June 1897 caused serious damage to most of the public buildings of the town. There is a railway station; a Government high school, with 284 pupils in 1896–97; and five printing-presses, with one vernacular periodical. The district comprises an area of 4118 square miles. Its population in 1881 was 1,514,346, and in 1891 was 1,555,835, giving an average density of 378 persons per square mile, being the lowest in the plains of the province. Classified according to religion, Hindus numbered 740,442; Mahommedans, 802,597; aborigines, 10,694; Christians, 511, of whom 30 were Europeans; "others," 1291. In 1901 the population was 1,569,133, showing an increase of 6 per cent. The land revenue and rates were Rs.16,26,711; the number of police was 423; the number of boys at school in 1896–97 was 22,489, being 18·4 per cent. of the male population of school-going age; the registered death-rate in 1897 was 34·72 per thousand. The district is partly traversed by the main line of the Eastern Bengal Railway and by two branch lines.

**Dinan,** chief town of arrondissement, department of Côtes-du-Nord, France, 35 miles east by south of St Brieuc, on railway from that town to St Malo. In a suburb of the town are many English residents. The new lycée (1892)

is installed in a fine building, and the public library now contains about 90,000 volumes. The principal manufactures now are farming implements and earthenware. During the bathing season steamboats ply regularly between Dinan and St Malo. The old cemetery of the church of St Sauveur has been converted into a public garden. Population (1881), 7893; (1896), 7828, (comm.) 8462; (1901), 10,534.

**Dinapur,** a town of British India, in the Patna district of Bengal, on the right bank of the Ganges, 12 miles west of Patna city by rail. In 1881 it had a population of 37,893, and in 1891 of 44,419. It is the largest military cantonment in Bengal, with accommodation for two batteries of artillery, a European and a native infantry regiment.

**Dindigul,** a town of British India, in the Madura district of Madras, 880 feet above the sea, 40 miles from Madura by rail. In 1881 it had a population of 14,182, and in 1891 of 20,115; the municipal income in 1897–98 was Rs.32,070. Dindigul has risen into importance as the centre of a trade in tobacco and manufacture of cigars, which are exported to England. There are now two large European cigar factories here. It has manufactures of silk, muslin, and blankets, and an export trade in hides and cardamoms; and there is a large native Christian population, with two churches. It also has a municipal high school and two printing-presses.

**Dindorf, Wilhelm** (1802–1883), German classical scholar, was born at Leipzig, 2nd January 1802, and was the son of the university professor of Oriental languages. From his earliest years he showed a strong partiality for classical studies, and after completing Invernizzi's edition of Aristophanes at an early age, and editing several grammarians and rhetoricians, was in 1828 appointed professor of literary history in his native city. Finding, however, that the duty of lecturing interfered too much with his philosophical pursuits, he resigned this office in 1833, and devoted himself entirely to Hellenic studies. His attention was at first chiefly given to Athenæus, whom he edited in 1827, and to the Greek dramatists, all of whom he edited separately and combined in his *Poetae Scenici Graeci* (1830). He also wrote a work on the metres of the dramatic poets, and compiled special lexicons to Æschylus and Sophocles. He edited Procopius and other historians for Niebuhr's great *Corpus* of the Byzantine writers, and between 1846 and 1851 brought out at Oxford a highly important edition of Demosthenes; he also edited Lucian and Josephus for the Didot Classics. His last important editorial labour was his *Eusebius of Cæsarea* (1867–71). Much of his attention was occupied by the great republication of Stephanus's *Thesaurus* (Paris, 1832–65), chiefly executed by him and his brother Ludwig, a work of prodigious labour and utility. His reputation suffered somewhat through the imposture practised upon him by the Greek Constantine Simonides, who succeeded in deceiving him by a fabricated fragment of the Greek historian Uranius. The book was printed, and a few copies had been circulated, when the forgery was discovered, just in time to prevent its being given to the world under the auspices of the University of Oxford. Dindorf died on 1st August 1883.—His brother LUDWIG (1805–1871) was born at Leipzig on 3rd January 1805, and died there on 6th September 1871. Like Wilhelm, he declined academical office, and he secluded himself so entirely for study that many doubted his existence, and affirmed that he was a mere pseudonym. The important share which he took in the edition of Stephanus's *Thesaurus* is nevertheless authenticated by his own signature to his contributions, and he published valuable editions of Polybius, Dion Cassius, and other Greek historians. (R. G.)

**D'Indy, Paul-Marie-Théodore-Vincent** (1851– ——), French musical composer, was born in Paris, 27th March 1851. He studied composition under César Franck, the organ at the Paris Conservatoire, and obtained the Grand Prize offered by the city of Paris in 1885 with *Le Chant de la Cloche*, a dramatic legend after Schiller. His principal works, beside the above, are the symphonic trilogy *Wallenstein*, the symphonic works entitled *Sauge fleuri*, *La Forêt enchantée*, *Istar*, *Symphonie sur un air montagnard français*; overture to *Anthony and Cleopatra*; *Ste Marie Magdeleine*, a cantata; *Attendez moi sous l'orme*, a one-act opera; *Fervaal*, a musical drama in three acts. Vincent d'Indy is perhaps the most prominent among the disciples of César Franck. Imbued with very high aims, he has always been guided by a lofty ideal, and very few musicians have attained so complete a mastery over the art of instrumentation. His music, however, lacks simplicity, and can never become popular in the widest sense. His opera *Fervaal*, which is styled "action musicale," is constructed upon the system of *Leit motifs*. Its legendary subject recalls both *Parsifal* and *Tristan*, and the music is also suggestive of Wagnerian influence. D'Indy can scarcely be considered so typical a representative of modern French music as his juniors Alfred Bruneau, the composer of *Le Rêve*, *L'Attaque du Moulin*, *Messidor*, or Gustave Charpentier, the author of *Louise*, who have chosen subjects of modern life for their operatic works. He nevertheless occupies a distinguished position as one of the most gifted among the musicians of his country.

**Dineir,** a small town in Asia Minor, built amidst the ruins of Celænæ-Apamea, near the sources of the Mæander (Mendere), is the terminus of the Smyrna-Aidin-Dineir Railway. The population numbers 1400. (See APAMEA.)

**Dingelstedt, Franz von,** BARON (1814–1881), German poet and dramaturgist, was born at Halsdorf, in Hesse Cassel, 30th June 1814. In 1836 he became a teacher at the Government school at Cassel, from which, having given offence to the authorities, he was transferred to Fulda in 1838. Despairing of being reinstated, he resolved to abandon his profession for literature, and in 1841 obtained an appointment on the staff of the *Augsburger Allgemeine Zeitung*. He had previously, in 1839 and 1840 respectively, produced a novel, *Unter der Erde*, which obtained considerable success, and a play, *Gespenst der Ehre* ("The Phantom of Honour"), which proved an utter failure. In 1841 appeared the book by which he is likely to be best remembered, the *Lieder eines kosmopolitischen Nachtwächters*, a most effective contribution to the political poetry of the day, animated with a spirit of bitter opposition to the prevalent despotism and distinguished by great sarcastic power. Extreme, therefore, was the surprise when, in 1844, the satirist of German princes accepted the appointment of private librarian to the King of Wurtemberg, and he was unanimously denounced as a renegade. In reality, his political convictions had never been very deep, and his hostile attitude towards the rulers was chiefly inspired by a spirit of scepticism and irony, to which the Liberals were as obnoxious as their opponents. His marriage in 1843 with the celebrated actress Jenny Lutzer probably had much influence on his decision. In 1845 he published a volume of poems, some of which, treating of modern life, possessed great literary rather than strictly poetical merit. A subsequent collection, published in 1852, attracted little attention. In 1850 a tragedy on the House of Barneveldt obtained

great success, and it still ranks as one of the best German plays of the period. In the following year he accepted an invitation to undertake the direction of the Royal Theatre at Munich. He proved one of the ablest managers that Germany had ever seen, but incurred the animosity of the Jesuit clique about the court, and in 1856 was suddenly dismissed on the most frivolous charges. A similar engagement was soon offered to him at Weimar through the influence of Liszt, and, although not altogether easy in his situation, he remained there until 1867. His administration was most successful, and he especially distinguished himself by putting all Shakespeare's historical plays upon the stage. In 1867 he removed to Vienna, and directed the Imperial Theatre there until his death in 1881. Among his other works may be noticed an autobiographical sketch of his Munich career, entitled *Münchener Bilderbogen* (1879), *Die Amazone*, an art novel of considerable merit (1869), translations of several of Shakespeare's comedies, and a treatise on the theatrical administration which he understood so well. His life, founded on his posthumous papers, was written by Julius Rodenberg in 1890. He was ennobled by the Emperor of Austria. Dingelstedt possessed few qualifications for the higher walks of poetry, but his style both in prose and verse was admirable, and he might have been the poet of modern social life. It is probable that the imputation of political apostasy under which he laboured impeded the full exercise of his abilities. (R. G.)

**Dingwall,** a market-town, royal and parliamentary burgh (Wick group), railway station, and county town of Ross-shire, Scotland, on the north-west shore of the Cromarty Firth, 13½ miles north-west of Inverness. A small harbour opens on to the Peffer river. There are county buildings, militia barracks, public hall, a cottage hospital, and a public park. There is an academy. Population (1891), 2300; (1901), 2519.

**Dinkar Rao, Sir,** Raja (1819–1896), Indian statesman, was born in Ratnagiri on 20th December 1819, being a Maratha Brahman. At fifteen he entered the service of the Gwalior state, in which his ancestors had served. Rapidly promoted to the responsible charge of a division, he displayed unusual talents in reorganizing the police and revenue departments, and in reducing chaos to order. In 1852 Dinkar Rao became Dewan. The events which led to the British victories of Maharajpur and Panniar in 1844 had filled the state with mutinous soldiery, ruined the finances, and weakened authority. With a strong hand the Dewan suppressed disorder, abolished ruinous imposts, executed public works, and by a reduction of salaries, including his own, turned a deficit into a surplus. When the contingent mutinied, he never wavered in loyalty; and although the state troops also mutinied in June 1858 on the approach of Tantia Topi, he adhered to the British cause, retiring with the Maharaja Sindhia to the Agra fort. After the restoration of order he remained minister until December 1859, when he resigned. In 1873 he was appointed guardian to the minor Rana of Dholpur, but soon afterwards he resigned, owing to ill-health. In 1875 the Viceroy selected him as a Commissioner, with the Maharajas Sindhia and Jaipur, and three British colleagues, to try the Gaekwar of Baroda on a charge of attempting to poison the British Resident. No higher honour could have been conferred on a British subject. He served in the Legislative Council of India, and was frequently consulted by Viceroys on difficult questions. An estate was conferred upon him, and the hereditary title of Raja, for his eminent services, and he also received the decoration of K.C.S.I. He died on 9th January 1896. No Indian statesman of the 19th century gained a higher reputation, yet he possessed none of the qualifications which entitled Salar Jung, Madava Rao, Ranga Charlu, or Sheshadri Aiyar to fame. He only commenced the study of English at the age of forty, and was never able to converse fluently in it; his orthodoxy resented social reforms; he kept aloof from the Congress, and he had received no training in British administration. Finally he resigned the service in Gwalior and Dholpur just when his work seemed likely to bear most fruit. But the verdict of posterity has endorsed the favourable opinion entertained by his contemporaries. (W. L.-W.)

**Diognetus, Epistle to.**—The one manuscript which contained this letter perished by fire at Strasburg in 1870, but happily it had been accurately collated by Reuss nine years before. It formed part of a collection of works supposed to be by Justin Martyr, and to this mistaken attribution its preservation is no doubt due. The end of it is lost, but there followed in the codex the end of a homily, which was attached without a break to the epistle: this points to the loss in some earlier codex of pages containing the end of the letter and the beginning of the homily.

Diognetus has expressed a desire to know what Christianity really means—"What is this new race" of men who are neither pagans nor Jews? "What is this new interest which has entered into men's lives now and not before?" The answer begins with a refutation of the folly of worshipping idols, fashioned by human hands and needing to be guarded if of precious material. The repulsive smell of animal sacrifices is enough to show their monstrous absurdity. Next Judaism is attacked. Jews abstain from idolatry and worship one God, but they fall into the same error of repulsive sacrifice, and have absurd superstitions about meats and sabbaths, circumcision and new moons. So far the task is easy; but the mystery of the Christian religion "think not to learn from man." A passage of great eloquence follows, showing that Christians have no obvious peculiarities that mark them off as a separate race. In spite of blameless lives they are hated. Their home is in heaven, while they live on earth. "In a word, what the soul is in a body, this the Christians are in the world. . . . The soul is enclosed in the body, and yet itself holdeth the body together: so Christians are kept in the world as in a prison-house, and yet they themselves hold the world together." This strange life is inspired in them by the almighty and invisible God, who sent no angel or subordinate messenger to teach them, but His own Son by whom He created the universe. No man could have known God, had He not thus declared Himself. "If thou too wouldst have this faith, learn first the knowledge of the Father. For God loved men, for whose sake He made the world . . . Knowing Him, thou wilt love Him and imitate His goodness; and marvel not if a man can imitate God: he can, if God will." By kindness to the needy, by giving them what God has given to him, a man can become "a god of them that receive, an imitator of God." "Then shalt thou on earth behold God's life in heaven; then shalt thou begin to speak the mysteries of God." A few lines after this the letter suddenly breaks off.

Even this rapid summary may show that the writer was a man of no ordinary power. Both his thought and his language mark him off entirely from Justin Martyr. Bishop Lightfoot, who speaks of the letter as "one of the noblest and most impressive of early Christian apologies," places it *c.* 150 A.D., and inclines to identify Diognetus with the tutor of M. Aurelius. Harnack would place it later, perhaps in the 3rd century. There are some striking parallels in method and language to the Apology of Aristides, and also to the early "Preaching of Peter,"

of which Aristides also has made considerable use (see ARISTIDES, APOLOGY OF).

The Epistle may be read in Lightfoot's *Apostolic Fathers* (ed. min.), where there is also a translation into English.

(J. A. R.)

**Diomedes, The.**—Two small islands situated in the middle of Bering Strait, about a mile apart, between which passes the boundary line between the possessions of Russia and the United States. They are granite domes without a harbour, and are occupied by a small tribe of Eskimo (85 in 1890), who have plied the trade of middlemen between Asia and America from prehistoric times. They are situated in N. lat. 65° 46′; the western is called by the natives Nunárbook, and the eastern, Ignálook. They were discovered by Deshneff in 1648.

**Diósgyör,** a market-town of Northern Hungary, $5\frac{1}{2}$ miles west of Miskolcz. Population (1891), 6537; (1900), 11,526. The state has here some of the largest iron and steel works in the country, employing regularly, in company with the mines, 6000 men. To accommodate these, two large barracks have been erected, besides numerous houses; also schools, hospitals, and other institutions. A large paper-mill likewise deserves mention. The Hungarian kings in old times used often to visit the now dismantled fortress.

**Diphtheria.**—Great attention has been paid to diphtheria in recent years, with some striking results. Its cause and nature have been definitely ascertained, the conditions which influence its prevalence have been elucidated, and a specific "cure" has been found. In the last respect it occupies a unique position at the present time. In the case of several other zymotic diseases much has been done by way of prevention, little or nothing for treatment; in the case of diphtheria prevention has failed, but treatment has been revolutionized by the introduction of antitoxin, which constitutes the most important contribution to practical medicine as yet made by bacteriology.

*Causation.*

The exciting cause of diphtheria is a micro-organism, identified by Klebs and Löffler in 1883. A description of it will be found under the heading of PATHOLOGY (*Parasitic Diseases*). It has been shown by experiment that the symptoms of diphtheria, including the after-effects, are produced by a toxin derived from the micro-organisms which lodge in the air-passages and multiply in a susceptible subject. The natural history of the organism outside the body is not well understood, but there is some reason to believe that it lives in a dormant condition in suitable soils. Recent research does not favour the theory that it is derived from defective drains or "sewer gas," but these things, like damp and want of sunlight, probably promote its spread, by lowering the health of persons exposed to them, and particularly by causing an unhealthy condition of the throat, rendering it susceptible to the contagion. Defective drainage, or want of drainage, may also act, by polluting the ground, and so providing a favourable soil for the germ, though it is to be noted that "the steady increase in the diphtheria mortality has coincided, in point of time, with steady improvement in regard of such sanitary circumstances as water supply, sewerage, and drainage" (Thorne Thorne). Cats and cows are susceptible to the diphtheritic bacillus, and fowls, turkeys, and other birds have been known to suffer from a disease like diphtheria, but other domestic animals appear to be more or less resistant or immune. In human beings the mere presence of the germ is not sufficient to cause disease; there must also be susceptibility, but it is not known in what that consists. Individuals exhibit all degrees of resistance up to complete immunity. Children are far more susceptible than adults, but even children may have the Klebs-Löffler bacillus in their throats without showing any symptoms of illness. Altogether there are many obscure points about this micro-organism, which is apt to assume a puzzling variety of forms. Nevertheless its identification has greatly facilitated the diagnosis of the disease, which was previously a very difficult matter, often determined in an arbitrary fashion on no particular principles. Diphtheria, as at present understood, may be defined as sore throat in which the bacillus is found; if it cannot be found, the illness is regarded as something else, unless the clinical symptoms are quite unmistakable. One result of this is a large transference of registered mortality from other throat affections, and particularly from croup, to diphtheria. Croup, which never had a well-defined application, and is not recognized by the College of Physicians as a synonym for diphtheria, appears to be dying out from the medical vocabulary in Great Britain. In France the distinction has never been recognized.

*Prevalence.*

Diphtheria is endemic in all European and American countries, and is apparently increasing, but the incidence varies greatly. It is far more prevalent on the Continent than in England, and still more so in the United States and Canada. The following table, compiled from figures collected by Dr Newsholme, shows how London compares with some foreign cities. The figures give the mean death-rate from diphtheria and croup for the term of years during which records have been kept. The period varies in different cases, and therefore the comparison is only a rough one.

*Mean Death-Rates from Diphtheria and Croup per Million living.*

| | | | |
|---|---|---|---|
| New York | 1610 | Munich | 990 |
| Chicago | 1400 | Milan | 990 |
| Buenos Aires | 1360 | Florence | 830 |
| Trieste | 1300 | Vienna | 770 |
| Dresden | 1290 | Stockholm | 720 |
| Berlin | 1190 | St Petersburg | 650 |
| Boston | 1160 | Moscow | 640 |
| Marseilles | 1130 | Paris | 630 |
| Christiania | 1090 | Hamburg | 490 |
| Budapest | 1880 | London | 386 |

There is comparatively little diphtheria in India and Japan, but in Egypt, the Cape, and Australasia it prevails very extensively among the urban populations. The mortality varies greatly from year to year in all countries and cities. In Berlin, for instance, it has oscillated between a maximum of 2420 in 1883 and a minimum of 340 in 1896; in New York between 2760 in 1877 and 680 in 1868; in Christiania between 3290 in 1887 and 170 in 1871. In some American cities still higher maxima have been recorded. In other words, diphtheria, though always endemic, exhibits at times a great increase of activity, and becomes epidemic or even pandemic. The following table shows fairly well the periodical rise and fall in England and Wales. Diphtheria and croup are given both separately and together, showing the increasing transference from one to the other of late years. Diphtheria was first entered separately in the year 1859, with which the table begins.

*Deaths from Diphtheria and Croup per Million living in England and Wales.*

| Years. | Diphtheria. | Croup. | Diphtheria and Croup. |
|---|---|---|---|
| 1859 | 517 | 286 | 803 |
| 1860 | 261 | 220 | 481 |
| 1861–70 | 185 | 246 | 431 |
| 1871–80 | 121 | 168 | 289 |
| 1881–90 | 163 | 144 | 307 |
| 1891–95 | 254 | 70 | 324 |
| 1896–97 | 269 | 43 | 312 |
| 1898 | 244 | 27 | 271 |
| 1899 | 293 | 32 | 325 |

Several facts are roughly indicated by this table. It begins with an extremely severe epidemic, which has not been approached since. Then follows a fall extending over twenty years. On the whole this diminution was progressive, though not in reality so steady as the decennial grouping makes it appear, being interrupted by smaller oscillations in single years and groups of years. Still the main fact holds good. After 1880 an opposite movement began, likewise interrupted by minor oscillations, but on the whole progressive, and culminating in the year 1893 with a death-rate of 389, the highest recorded since 1865. After 1896 a marked fall again took place. This is partly accounted for by the use of antitoxin, which only began on a considerable scale in 1895, and did not become general until a year or two later at least. Probably its effects are only now being fully felt, and they undoubtedly affect the Registrar-General's returns, which record mortality, not prevalence—that is to say, the number of deaths, not of cases. The factor, therefore, must not be forgotten, but it can hardly account for the whole of the diminution.

On the whole, we get clear evidence of an epidemic rise and fall, which may serve to dispose of some erroneous conceptions. The belief, held until recently, that diphtheria is steadily increasing in Great Britain was obviously premature; it did rise over a series of years, but has now ebbed again. Moreover, the general prevalence during the last thirty years has been notably less than in the previous twelve years. Yet it is during years since 1870 that compulsory education has been in existence and main drainage chiefly carried out. It follows that neither school attendance nor sewer gas exercises such an important influence over the epidemicity of diphtheria as some other conditions. What are those conditions? Dr Newsholme has advanced the theory, based on an elaborate examination of statistics in various countries, that the activity of diphtheria is connected with the rainfall, and he lays down the following general induction from the facts: "Diphtheria only becomes epidemic in years in which the rainfall is deficient, and the epidemics are on the largest scale when three or more years of deficient rainfall follow each other." He points out that the comparative rarity of diphtheria in tropical climates, which are characterized by excessive rainfall, and its greater prevalence in continental than in insular countries, confirm his theory. His observations seem quite contrary to the view laid down by various authorities, and hitherto generally accepted, that wet weather favours diphtheria. The two, however, are not irreconcilable. The key to the problem—and possibly to many other epidemiological problems—may perhaps be found in the movements of the subsoil water. It has been suggested by different observers, and particularly by Mr M. A. Adams, who has for some years made a study of the subsoil water at Maidstone, that there is a definite connexion between it and diphtheria. In England the underground water normally reaches its lowest level at the end of the summer; then it gradually rises, fed by percolation from the winter rains, reaching a maximum level about the end of March, after which it gradually sinks. This maximum level Mr Adams calls the annual spring cleaning of the soil, and his observations go to show that when the normal movement is arrested or disturbed, diphtheria becomes active. Now that is what happens in periods of drought. The underground water does not rise to its usual level, and there is no spring cleaning. The hypothesis, then, is this: The diphtheria bacillus lives in the soil, but is "drowned out" in wet periods by the subsoil water. In droughty ones it lives and flourishes in the warm, dry soil; then when rain comes, it is driven out with the ground air into the houses. This process will continue for some time, so that epidemic outbreaks may well seem to be associated with wet. But they begin in drought, and are stopped by long-continued periods of copious rainfall. This is quite in keeping with the observed fact that diphtheria is a seasonal disease, always most prevalent in the last quarter of the year. The summer develops the poison in the soil, the autumnal rains bring it out. The fact that the same cause does not produce the same effect in tropical countries may perhaps be explained by the extreme violence of the alternations, which are too great to suit this particular micro-organism, or possibly the regularity of the rainfall prevents its development.

The foregoing hypothesis is supported by a good deal of evidence, and notably by the concurrence of the great epidemic or pandemic prevalence in Great Britain, culminating in 1859, with a prolonged period of exceptionally deficient rainfall. Again, the highest death-rate registered since 1865 was in 1893, a year of similarly exceptional drought. But it is no more than an hypothesis, and the fate of former theories is a warning against drawing conclusions from statistics and records extending over too short a period of time. The warning is particularly necessary in connexion with meteorological conditions, which are apt to upset all calculations. As it happens, a period of deficient rainfall even greater than that of 1854–58 has recently been experienced. It began in 1893 and culminated in the extraordinary season of 1899. The dry years were 1893, 1895, 1896, 1898, and 1899, and the deficiency of rainfall was not made good by any considerable excess in 1894 and 1897. It surpassed all records at Greenwich; streams and wells ran dry all over the country, and the flow of the Thames and Lea was reduced to the lowest point ever recorded. There should be, according to the theory, at least a very large increase in the prevalence of diphtheria. To a certain extent it has held good. There was a marked rise in 1893–96 over the preceding period, though not so large as might have been expected, but it was followed by a decided fall in 1897–98. The experience of 1898 contradicts, that of 1899 supports, the theory. Further light is therefore required; but perhaps the failure of the recent drought to produce results at all comparable with the epidemic of the 'fifties may be due to variations in the resistance of the disease, which differs widely in different years. It may also be due in part to improved sanitation, to the notification of infectious diseases, the use of isolation hospitals, which have greatly developed in quite recent years, and, lastly, to the beneficial effects of antitoxin. If these be the real explanations, then scientific and administrative work has not been thrown away after all in combating this very painful and fatal enemy of the young.

***Dissemination.***

The conditions governing the general prevalence of diphtheria, and its epidemic rise and fall, which have just been discussed, do not touch the question of actual dissemination. The contagion is spread by means which are in constant operation, whether the general amount of disease is great or small. Water, so important in some epidemic diseases, is believed not to be one of them, though a negative proof based on absence of evidence cannot be accepted as conclusive. On the other hand, milk is undoubtedly a means of dissemination. Several outbreaks of an almost explosive character, besides minor extensions of disease from one place to another, have been traced to this cause. Milk may be contaminated in various ways,—at the dairy, for instance, or on the way to customers,—but several cases, investigated by the officers of the Local Government Board and others, have been thought to point to infection from cows suffering from a diphtheritic affection of the udder. The part played by aerial convection is undetermined, but there is no reason to suppose that the infecting material is conveyed any distance by wind or air currents. Instances which seem to point to the contrary

may be explained in other ways, and particularly by the fact, now fully demonstrated, that persons suffering from minor sore throat, not recognized as diphtheria, may carry the disease about and introduce it into other localities. Human intercourse is the most important means of dissemination, the contagion passing from person to person either by actual contact, as in kissing, or by the use of the same utensils and articles, or by mere proximity. In the last case the germs must be supposed to be air-borne for short distances, and to enter with the breath. Rooms appear liable to become infected by the presence of diphtheritic cases, and so spread the disease among other persons using them. At a small outbreak which occurred at Darenth Asylum in 1898 the infection clung obstinately to a particular ward, in spite of the prompt removal of all cases, and fresh ones continued to occur until it had been thoroughly disinfected, after which there were no more. The part played by human intercourse in fostering the spread of the disease suggests that it would naturally be more prevalent in urban communities, where people congregate together more, than in rural ones. This is at variance with the conclusion laid down by some authorities, that in this country diphtheria used to affect chiefly the sparsely populated districts, and though tending to become more urban, is still rather a rural disease. That view is based upon an analysis of the distribution by counties in England and Wales from 1855 to 1880, and it has been generally accepted and repeated until it has become a sort of axiom. Of course the facts of distribution are facts, but the general inference drawn from them, that diphtheria peculiarly affects the country and is changing its *habitat*, may be erroneous. Dr Newsholme, by taking a wider basis of experience, has arrived at the opposite conclusion, and finds that diphtheria does not, in fact, flourish more in sparsely peopled districts. "When a sufficiently long series of years is taken," he says, "it appears clear that there is more diphtheria in urban than in rural communities." The rate for London has always been in excess of that for the whole of England and Wales. Its distribution at any given time is determined by a number of circumstances, and by their incidental co-operation, not by any property or predilection for town or country inherent in the disease. There are the epidemic conditions of soil and rainfall, previously discussed, which vary widely in different localities at different times; there is the steady influence of regular intercourse, and the accidental element of special distribution by various means. These things may combine to alter the incidence. In short, accident plays too great a part to permit any general conclusion to be drawn from distribution, except from a very wide basis of experience. The variations are very great and sometimes very sudden. For instance, the county of London has for years headed the list, having a far higher death-rate than any other. In 1898 it dropped to the fifth place, and was surpassed by Rutland, a purely rural county, which had the lowest mortality of all in the previous year and very nearly the lowest for the previous ten years. Again, South Wales, which had a low mortality for some years, has recently and rapidly become a diphtheria district, and in 1898 had the highest death-rate in the whole country. Staffordshire and Bedfordshire show a similar rise, the one an urban, the other a rural, county. All the northern counties, both rural and urban,—namely, Northumberland, Durham, Cumberland, Westmorland, Lancashire, Yorkshire, Cheshire, and Lincolnshire,—had a very high rate in 1861–70, and a low one in 1896–98. It is obviously unsafe to draw general conclusions from distribution data on a small scale. Diphtheria appears to creep about very slowly, as a rule, from place to place, and from one part of a large town to another; it forsakes one district and appears in another; occasionally it attacks a fresh locality with great energy, presumably because the local conditions are exceptionally favourable, which may be due to the soil or, possibly, to the susceptibility of the inhabitants, who are, so to speak, virgin ground. But through it all personal infection is the chief means of spread.

The acceptance of this doctrine has directed great attention to the practical question of school influence. There is no doubt whatever that it plays a very considerable part in spreading diphtheria. The incidence of the disease is chiefly on children, and nothing so often and regularly brings large numbers together in close contact under the same roof as school attendance. Nothing, in fact, furnishes such constant and extensive opportunities for personal infection. Many outbreaks have definitely been traced to schools. In London the subject has been very fully investigated by Dr Shirley Murphy, the Medical Officer of Health to the County Council, and by Dr W. R. Smith, who fills the same post for the London School Board. Dr Murphy has shown that a special incidence on children of school age began to manifest itself after the adoption of compulsory education, and that the summer holidays are marked by a distinct diminution of cases, which is succeeded by an increase on their return to school. Dr W. R. Smith's observations are directed rather to minimizing the effect of school influence, and to showing that it is less important than other factors; which is doubtless true, as has been already remarked. It appears that the heaviest incidence falls upon infants under school age, and that liability diminishes progressively after school age is reached. But this by no means disposes of the importance of school influence, as the younger children at home may be infected by older ones, who have picked up the contagion at school, but, being less susceptible, are less severely affected and exhibit no worse symptoms than a sore throat. From a practical point of view the problem is a difficult one to deal with, as it is virtually impossible to ensure the exclusion of all infection, on account of the deceptively mild forms it may assume; but considering how very often outbreaks of diphtheria necessitate the closing of schools, it would probably be to the advantage of the authorities to discourage, rather than to compel, the attendance of children with sore throats. A fact of some interest revealed by statistics is that in the earliest years of life the incidence of diphtheria is greater upon male than upon female children, but from three years onwards the position is reversed, and with every succeeding year the relative female liability becomes greater. This is probably due to the habit of kissing maintained among females, but more and more abandoned by boys from babyhood onwards. It emphasizes the part played by personal infection.

All these considerations suggest the importance of segregating the sick in isolation hospitals. Of late years this preventive measure has been carried out with increasing efficiency, owing to the better provision of such hospitals and the greater willingness of the public to make use of them; and probably the improvement so effected has had some share in keeping down the prevalence of the disease to comparatively moderate proportions. Unfortunately, the complete segregation of infected persons is hardly possible, because of the mild symptoms, and even absence of symptoms, exhibited by some individuals. A further difficulty arises with reference to the discharge of patients. It has been proved that the bacillus may persist almost indefinitely in the air-passages in certain cases, and in a considerable proportion it does persist for several weeks after convalescence. On returning home such cases may, and often do, infect others.

Since antitoxin was introduced in 1894 it has overshadowed all other methods of treatment. We owe this drug originally to the Berlin school of bacteriologists, and particularly to Dr Behring. The idea of making use of serum arose about 1890, out of researches made in connexion with Metschnikoff's theory of phagocytosis, by which is meant the action of the phagocytes or white corpuscles of the blood in destroying the bacteria of disease. It was shown by the German bacteriologists that the serum or liquid part of the blood plays an equally or more important part in resisting disease, and the idea of combating the toxins produced by pathogenic bacteria with resistant serum injected into the blood presented itself to several workers. The idea was followed up and worked out independently in France and Germany, so successfully that by the year 1894 the serum treatment had been tried on a considerable scale with most encouraging results. Some of these were published in Germany in the earlier part of that year, and at the International Hygienic Congress, held in Budapest a little later, Dr Roux, of the Institut Pasteur, whose experience was somewhat more extensive than that of his German colleagues, read a paper giving the result of several hundred cases treated in Paris. When all allowance for errors had been made, they showed a remarkable and even astonishing reduction of mortality, fully confirming the conclusions drawn from the German experiments. This consensus of independent opinion proved a great stimulus to further trial, and before long one *clinique* after another told the same tale. The evidence was so favourable that Professor Virchow—the last man to be carried away by a novelty—declared it "the imperative duty of medical men to use the new remedy" (*The Times*, 19th October 1894). Since then an enormous mass of facts has accumulated from all quarters of the globe, all testifying to the value of antitoxin in the treatment of diphtheria. The experience of the hospitals of the London Metropolitan Asylums Board for five years may be given as a particularly instructive illustration, because it represents a prolonged experiment on an immense scale, and because the mortality was already comparatively low in those hospitals before the use of antitoxin.

*Treatment.*

*Annual Case Mortality in Metropolitan Asylums Board's Hospitals.*

| Before Antitoxin. | | After Antitoxin. | |
|---|---|---|---|
| Year. | Mortality per cent. | Year. | Mortality per cent. |
| 1890 | 33·55 | 1895 | 22·85 |
| 1891 | 30·61 | 1896 | 21·20 |
| 1892 | 29·51 | 1897 | 17·79 |
| 1893 | 30·42 | 1898 | 15·37 |
| 1894 | 29·29 | 1899 | 13·95 |

The number of cases dealt with in the five antitoxin years was 32,835, or an average of 6567 a year, and the broad result is a reduction of mortality by more than one-half. It is a fair inference that the treatment saves the lives of about 1000 children every year in London alone. This refers to all cases. Those which occur in the hospitals as a sequel to scarlet fever, and consequently come under treatment from the commencement, show very much more striking results. The case mortality, which was 46·8 per cent. in 1892 and 58·8 per cent. in 1893, has been reduced to 3·6 per cent. since the introduction of antitoxin. But the evidence is not from statistics alone. The beneficial effect of the treatment is equally attested by clinical observation. Dr Roux's original account has been confirmed by a cloud of witnesses year after year. "One may say," he wrote, "that the appearance of most of the patients is totally different from what it used to be. The pale and leaden faces are scarcely seen in the wards; the expression of the children is brighter and more lively." Adult patients have described the relief afforded by inoculation; it acts like a charm, and lifts the deadly feeling of oppression off like a cloud in the course of a few hours. Finally, the counteracting effect of antitoxin in preventing the disintegrating action of the diphtheritic toxin on the nervous tissues has been demonstrated pathologically. There are some who still affect scepticism as to the value of this drug. They cannot be acquainted with the evidence, for if the efficacy of antitoxin in the treatment of diphtheria has not been proved, then neither can the efficacy of any treatment for anything be said to be proved. Prophylactic properties are also claimed for the serum; but protection is necessarily more difficult to demonstrate than cure, and though there is some evidence to support the claim, it has not been fully made out.

**Dirschau,** a town of Prussia, province of West Prussia, on the left bank of the Vistula, 20 miles south from Danzig and at the junction of important lines of railway. The river is here crossed by two fine iron bridges. The older structure dating from the year 1857, originally used for the railway, is now given up to road traffic, and the railway carried by a new bridge completed in 1891. Dirschau has railway workshops and manufactories of sugar, agricultural implements, and cement. During the war with Poland, Gustavus Adolphus made it his headquarters for many months after its capture in 1626. Population (1885), 11,146; (1900), 12,808.

**Distribution.** See Zoological Distribution.

**District of Columbia.** See Washington, the capital of the United States.

**Dittersbach,** a village of Prussia, prov. Silesia, 3 miles by rail south-east from Waldenburg and 50 miles south-west from Breslau. It has coal-mines, bleachfields, and match factories. Population (1900), 9371.

**Diu,** an island and town of India, belonging to Portugal, and situated at the south extremity of the peninsula of Kathiawar. Area of district, 20 square miles. Population, 13,206. Many of the inhabitants are the well-known Banyan merchants of the East Coast of Africa and Arabia. Native spirits are distilled from the palm, salt is made, and fish caught.

**Dividend,** the net profit periodically divisible among the proprietors of a joint-stock company in proportion to their respective holdings of its capital. Dividend is not interest, although the word dividend is frequently applied to payments of interest; and a failure to pay dividends to shareholders does not, like a failure to pay interest on borrowed money, lay a company open to being declared bankrupt. In bankruptcy a dividend is the proportionate share of the proceeds of the debtor's estate received by a creditor. The Companies Act, 1862, provides that no dividend shall be payable except out of the profits arising from the business of the company, but, in the case of companies incorporated by special Act of Parliament for the construction of railways and other public works which cannot be completed for a considerable time, it is sometimes provided that interest may during construction be paid to the subscribers for shares out of capital. All dividends are payable in cash, while the divi-

dends on the shares of a few American railroad companies are occasionally made payable either in cash or in new shares of the company at the proprietor's option. Most companies divide their capital into at least two classes, called "preference" shares and "ordinary" shares, of which the former are entitled out of the profits of the company to a preferential dividend at a fixed rate, and the latter to whatever remains after payment of the preferential dividend and any fixed charges. Before, however, a dividend is paid, a part of the profits is often carried to a "reserve fund." The dividend on preference shares is either "cumulative" or contingent on the profits of each separate year or half-year. When cumulative, if the profits of any one year are insufficient to pay it in full, the deficiency has to be made good out of subsequent profits. A cumulative preferential dividend is sometimes said to be "guaranteed," and preferential dividends payable by all companies registered under the Companies Acts, 1862 to 1900, are cumulative unless stipulated to be otherwise. Certain public companies are forbidden by Parliament to pay dividends in excess of a prescribed maximum rate, but this restriction has been happily modified in some instances, notably in the case of gas companies, by the institution of a sliding scale, under which a gas company may so regulate the price of gas to be charged to consumers that any reduction of an authorized standard price entitles the company to make a proportionate increase of the authorized dividend, and any increase above the standard price involves a proportionate decrease of dividend. Dividends are usually declared yearly or half-yearly; and before any dividend can be paid it is, as a rule, necessary for the directors to submit to the shareholders, at a general meeting called for the purpose, the accounts of the company, with a report by the directors on its position and their recommendation as to the rate of the proposed dividend. The articles of association of a company usually provide that the shareholders may accept the directors' recommendation as to dividend or may declare a lower one, but may not declare a higher one than the directors recommend. Directors frequently have power to pay on account of the dividend for the year, without consulting the shareholders, an "interim dividend," which on ordinary shares is generally at a much lower rate than the final or regular dividend. An exceptionally high dividend is often distributed in the shape of a dividend at the usual rate supplemented by an additional dividend or "bonus." Payment of dividends is made by means of cheques sent by post, called "dividend warrants." All dividends are subject to income-tax, and by most companies dividends are paid "less income-tax," in which case the tax is deducted from the amount of dividend payable to each proprietor. When paid without such deduction a dividend is said to be "free of income-tax." In the latter case, however, the company has to make provision for payment of the tax before declaring the dividend, and the amount of its divisible profits and the rate of dividend which it is able to declare are consequently to that extent reduced. In respect of consols and certain other securities, holders of amounts of less than £1000 may instruct the Bank of England or Bank of Ireland to receive and invest their dividends. With few exceptions, the prices of securities dealt in on the Stock Exchange include any accruing dividend not paid up to the date of purchase. As soon as a price ceases to include any accruing dividend, it is marked "ex dividend" or "x.d." The expression "cum dividend" is used to signify that the price of the security dealt in includes a dividend which, in the absence of any stipulation, might be supposed to belong to the seller of the security. (S. D. H.)

# DIVORCE.

DIVORCE is the dissolution, in whole or in part, of the tie of marriage. It includes both the complete abrogation of the marriage relation known as a divorce *a vinculo matrimonii*, which carries with it a power on the part of both parties to the marriage to remarry other persons or each other, and also that incomplete severance not involving powers to remarry, which was formerly known as divorce *a mensâ et thoro*, and has in England been termed "judicial separation." Less strictly, divorce is commonly understood to include judicial declarations of nullity of marriage, which, while practically terminating the marriage relation, proceed in law on the basis of the marriage never having been legally established. The conditions under which, in different communities, divorce has at different times been permitted, vary with the aspects in which the relation of marriage has been regarded. When marriage has been deemed to be the acquisition by the husband of property in the wife, or when it has been regarded as a mere agreement between persons capable both to form and to dissolve that contract, we find that marriage has been dissoluble at the will of the husband, or by agreement of the husband and wife. Yet even in these cases the interest of the whole community in the purity of marriage relations, in the pecuniary bearings of this particular contract, and the condition of children, has led to the imposition of restrictions on, and the attachment of conditions to, the termination of the obligations consequent on a marriage legally contracted. But the main restrictions on liberty of divorce have arisen from the conception of marriage entertained by religions, and especially by one religion. Christianity has had no greater practical effect on the life of mankind than in its belief that marriage is no mere civil contract, but a vow in the sight of God binding the parties by obligations of conscience above and beyond those of civil law. Translating this conception into practice, Christianity not only profoundly modified the legal conditions of divorce as formulated in the Roman civil law, but in its own canon law defined its own rule of divorce, going so far as in the Western (at least in its unreformed condition), though not the Eastern, branch of Christendom to forbid all complete divorces, that is to say, all dissolutions of marriage carrying with them the right to remarry.

*The Roman Law of Divorce before Justinian.*—The history of divorce, therefore, practically begins with the law of Rome. It took its earliest colour from that conception of the *patria potestas*, or the power of the head of the family over its members, which enters so deeply into the jurisprudence of ancient Rome. The wife was transferred at marriage to the authority of her husband, *in manus*, and consequently became so far subject to him that he could, at his will, renounce his rule over her, and terminate his companionship, subject at least to an adjustment of the pecuniary rights which were disturbed by such action. So clearly was the power of the husband derived from that of the father, that for a long period a father, in the exercise of his *potestas*, could take his daughter from her husband against the wishes of both. It may be presumed that this power, anomalous as it appears, was not unexercised, as we find that a constitution of Antoninus Pius prohibited a father from disturbing a harmonious union, and Marcus Aurelius afterwards limited this prohibition by allowing the interference of a father for strong

and just cause. *Magnâ et justâ causâ interveniente.* Except in so far as it was restrained by special legislation, the authority of a husband in the matter of divorce was absolute. As early indeed, however, as the time of Romulus, it is said that the State asserted its interest in the permanence of marriage by forbidding the repudiation of wives unless they were guilty of adultery or of drinking wine, on pain of forfeiture of the whole of an offender's property, one-half of which went to the wife, the other to Ceres. But the law of the XII. Tables, in turn, allowed freedom of divorce. It would appear, however, that the sense of the community was so far shocked by the inhumanity of treating a wife as mere property, or the risk of regarding marriage as a mere terminable contract, that, without crystallizing into positive enactment, it operated to prevent the exercise of so harsh and dangerous a power. It is said that for 500 years no husband took advantage of his power, and it was then only by an order of a Censor, however obtained, that Spurius Carvilius Ruga repudiated his wife for barrenness. We may, however, be permitted to doubt the genuineness of this Censorial order, or at least to conjecture the influence under which the Censor was induced to intervene, when we find that in another instance, that of L. Antonius, a Censor punished an unjust divorce by expulsion from the Senate, and that the exercise of their power by husbands increased to a great and alarming extent. Probably few of the admirers of the greatest of Roman orators have not regretted his summary and wholly informal repudiation of Terentia. At last the *lex Julia de adulteriis*, while recognizing a power of divorce both in the husband and in the wife, imposed on it, in the public interest, serious restrictions and consequences. It required a written bill of divorce (*libellus repudii*) to be given in the presence of seven witnesses, who must be Roman citizens of age, and the divorce must be publicly registered. The act was, however, purely an act of the party performing it, and no idea of judicial interference or contract seems to have been entertained. It was not necessary for either husband or wife giving the bill to acquaint the other with it before its execution, though it was considered proper to deliver the bill, when made, to the other party. In this way a wife could divorce a lunatic husband, or the *paterfamilias* of a lunatic wife could divorce her from her husband. But the *lex Julia* was also the first of a series of enactments by which pecuniary consequences were imposed on divorce both by husbands and wives, whether the intention was to restrain divorce by penalties of this nature, or to readjust pecuniary relations settled on the basis of marriage and disturbed by its rupture. It was provided that if the wife was guilty of adultery, her husband in divorcing her could retain one-sixth of her *dos*, but if she had committed a less serious offence, one-eighth. If the husband was guilty of adultery, he had to make immediate restitution of her dowry, or if it consisted of land, the annual proceeds for three years; if he was guilty of a less serious offence, he had six months within which to restore the *dos*. If both parties were in fault, no penalty fell on either. The *lex Julia* was followed by a series of acts of legislation extending and modifying its provisions. The legislation of Constantine, A.D. 331, specified certain causes for which alone a divorce could take place without the imposition of pecuniary penalties. There were three causes for which a wife could divorce her husband with impunity: (1) murder, (2) preparation of poisons, (3) violation of tombs; but if she divorced him for any other cause, such as drunkenness, or gambling, or immoral society, she forfeited her dowry and incurred the further penalty of deportation. There were also three causes for which a husband could divorce his wife without incurring any penalty: (1) adultery, (2) preparation of poisons, (3) acting as a procuress. If he divorced her for any other cause, he forfeited all interest in her dowry; and if he married again, the first wife could take the dowry of the second.

In A.D. 421 the emperors Honorius and Theodosius enacted a law of divorce which introduced limitations on the power of remarriage as an additional penalty in certain cases. As regards a wife: (1) if she divorced her husband for grave reasons or crime, she retained her dowry and could remarry after five years; (2) if she divorced him for criminal conduct or moderate faults, she forfeited her dowry, became incapable of remarriage, and liable to deportation, nor could the emperor's prerogative of pardon be exerted in her favour. As regards a husband: if he divorced his wife (1) for serious crime, he retained the dowry, and could remarry immediately; (2) for criminal conduct, he did not retain the dowry, but could remarry; (3) for mere dislike, he forfeited the property brought into the marriage, and could not remarry.

In A.D. 449 the law of divorce was rendered simpler and certainly more facile by Theodosius and Valentinian. It was provided that a wife could divorce her husband without incurring any penalty if he was convicted of any one of twelve offences: (1) treason, (2) adultery, (3) homicide, (4) poisoning, (5) forgery, (6) violating tombs, (7) stealing from a church, (8) robbery, (9) cattle-stealing, (10) attempting his wife's life, (11) beating his wife, (12) introducing immoral women to his house. If the wife divorced her husband for any other cause, she forfeited her dowry, and could not marry again for five years. A husband could divorce his wife without incurring a penalty for any of these reasons except the last, and also for the following reasons: (1) going to dine with men other than her relations without the knowledge or against the wish of her husband; (2) going from home at night against his wish without reasonable cause; (3) frequenting the circus, theatre, or amphitheatre after being forbidden by her husband. If a husband divorced his wife for any other reason, he forfeited all interest in his wife's dowry, and also any property he brought into the marriage.

The above sketch of the legislation prior to the time of Justinian, while it indicates a desire to place the husband and wife on something like terms of equality as regards divorce, indicates also, by its forbidding remarriage and by its pecuniary provisions in certain cases, a sense in the community of the importance in the public interest of restraining the violation of the contract of marriage. But to the Roman marriage was primarily a contract, and therefore side by side with this legislation there always existed a power of divorce by mutual consent. We must now turn to those principles of the Christian religion which, in combination with the legislation above described, produced the law formulated by Justinian.

*The Christian View of Divorce.*—The Christian law of divorce as enunciated by its Founder was expressed in a few words, but these, unfortunately, by no means of agreed interpretation. To appreciate them it is necessary to consider the enactment of the Mosaic law, which also was expressed in few words, but of a meaning involved in much doubt. The phrase in Deut. xxiv. 1–4, which is translated in the Authorized Version "some uncleanness," but in the Revised Version "some unseemly thing," and which is the only cause stated to justify the giving of a "bill of divorcement," was limited by the school of Shanmai to moral delinquency, but was extended by the rival school of Hillel to causes of trifling importance, or even to motives of caprice. The wider interpretation would seem to be supported by the words of Christ (Matt. v. 31), who, in indicating His own doctrine in contradistinc-

tion to the law of Moses, said, "Whosoever shall put away his wife, saving for the cause of fornication (πορνείας), causeth her to commit adultery; and whosoever shall marry her that is divorced committeth adultery." The meaning of these words of Christ Himself have been involved in controversy, which perhaps was nowhere carried on with greater acuteness or under more critical conditions than within the walls of the British Parliament during the passage of the Divorce Act of 1857. That they justify divorce of a complete kind for moral delinquency of some nature is supported by the opinion probably of every competent scholar. But scholars of eminence have sought to restrict the meaning of the λόγος πορνείας to antenuptial incontinence concealed from the husband, and to exclude adultery. The effect of this view commends itself to the adherents of the Church of Rome, because it places the right to separation between husband and wife, not on a cause supervening after a marriage, which that Church seeks to regard as absolutely indissoluble, but on invalidity in the contract of marriage itself, and which may therefore render the marriage liable to be declared void without impugning its indissoluble character when rightly contracted. The narrower view of the meaning of πορνείας has been maintained by, among others, Dr Döllinger (*First Ages of the Church*, ii. 226); but those who will consider the arguments of Professor Conington in reply to Dr Döllinger (*Contemp. Review*, May 1869) will probably assign the palm to the English scholar. A more general view points in the same direction. It is quite true that under the Mosaic law antenuptial incontinence was, as was also adultery, punishable with death. But when we consider the effect of adultery not only as a moral fault, but as violating the solemn contract of marriage and vitiating its objects, it is inconceivable that Christ, in employing a term of general import, intended to limit it to one kind, and that the less serious, of incontinence.

*Effect of Christianity on the Law of Rome.*—The modification in the civil law of Rome effected by Justinian under the joint influence of the previous law of Rome and that of Christianity was remarkable. Gibbon has summed up the change effected in the law of Rome with characteristic accuracy: "The Christian princes were the first who specified the just causes of a private divorce; their institutions from Constantine to Justinian appear to fluctuate between the customs of the empire and the wishes of the Church; and the author of the Novels too frequently reforms the jurisprudence of the Code and Pandects." Divorce by mutual consent, hitherto, as we have seen, absolutely free, was prohibited (Nov. 117) except in three cases: (1) when the husband was impotent; (2) when either husband or wife desired to enter a monastery; and (3) when either of them was in captivity for a certain length of time. It is obvious that the two first of these exceptions might well commend themselves to the mind of the Church, the former as being rather a matter of nullity of marriage than of divorce, the latter as admitting the paramount claims of the Church on its adherents, and not inconsistent with the spirit of the words of St Paul himself, who clearly contemplated a separation between husband and wife as allowable in case either of them did not hold the Christian faith (1 Cor. vii. 12). At a later period Justinian placed a further restriction or even prohibition on divorce by consent by enacting that spouses dissolving a marriage by mutual consent should forfeit all their property, and be confined for life in a monastery, which was to receive one-third of the forfeited property, the remaining two-thirds going to the children of the marriage. The cause stated for this remarkable alteration of the law, and the abandonment of the conception of marriage as a civil contract *ut non Dei judicium contemnatur* (Nov. 134), indicates the influence of the Christian idea of marriage. That influence, however, did not long continue in its full force. The prohibitions of Justinian on divorce by consent were repealed by Justin (Nov. 140), his successor. "He yielded," says Gibbon, "to the prayers of his unhappy subjects, and restored the liberty of divorce by mutual consent; the civilians were unanimous, the theologians were divided, and the ambiguous word which contains the precept of Christ is flexible to any interpretation that the wisdom of a legislature can demand." It was difficult, the enactment stated, "to reconcile those who once came to hate each other, and who, if compelled to live together, frequently attempted each other's lives."

Justinian further re-enacted, with some modifications, the power of divorce by a husband or wife against the will of the other. Divorce by a wife was allowed in five cases (Nov. 117): (1) the husband being party or privy to conspiracy against the State; (2) attempting his wife's life, or failing to disclose to her plots against it; (3) attempting to induce his wife to commit adultery; (4) accusing his wife falsely of adultery; (5) taking a woman to live in the house with his wife, or, after warning, frequenting a house in the same town with any woman other than his wife. If a wife divorced her husband for one of these reasons, she recovered her dowry and any property brought into the marriage by her husband for life with reversion to her children, or if there were no children, absolutely. But if she divorced him for any other reason, the provisions of the enactment of Theodosius and Valentinian were to apply. A husband was allowed to divorce his wife for any one of seven reasons: (1) failure to disclose to her husband plots against the State; (2) adultery; (3) attempting or failing to disclose plots against her husband's life; (4) frequenting dinners or balls with other men against her husband's wishes; (5) remaining from home against the wishes of her husband, except with her parents; (6) going to the circus, theatre, or amphitheatre without the knowledge or contrary to the prohibition of her husband; (7) procuring abortion. If the husband divorced his wife for any one of these reasons he retained the dowry absolutely, or if there were children, with reversion to them. If he divorced her for any other reason, the enactments of Theodosius and Valentinian applied. In any case of a divorce, if the father or mother of either spouse had advanced the dowry and it would be forfeited by an unreasonable divorce, the consent of the father or mother was necessary to render the divorce valid.

*Effect of Divorce on Children in the Law of Rome.*—The custody of the children of divorced parents was dealt with by the Roman law in a liberal manner. A constitution of Diocletian and Maximian left it to the judge to determine in his discretion to which of the parents the children should go. Justinian enacted that divorce should not impair the rights of children either as to inheritance or maintenance. If a wife divorced her husband for good cause, and she remained unmarried, the children were to be in her custody, but to be maintained by the father; but if the mother was in fault, the father obtained the custody. If he was unable, from want of means, to support them, but she was able to do so, she was obliged to take them and support them. It is interesting to compare these provisions as to children with the practice at present under English law, which in this respect reflects so closely the spirit of the law of Rome.

*The Canon Law of Divorce.*—The canon law of Rome was based on two main principles: (1) That there could be no divorce *a vinculo matrimonii*, but only *a mensâ et thoro*. The rule was stated in the most absolute terms:

"*Quamdiu vivit vir licet adulter sit, licet sodomita, licet flagitiis omnibus coopertus, et ab uxore propter hæc scelera derelictus, maritus ejus reputatur, cui alterum vivum accipere non licet*" (Caus. 32, Quæst. 7, c. 7). (2) That no divorce could be had at the will of the parties, but only by the sentence of a competent, that is to say, an ecclesiastical, court. In this negation of a right to divorce *a vinculo matrimonii* lies the broad difference between the doctrines of the Eastern and Western Churches of Christendom. The Greek Church, understanding the words of Christ in the broader sense above mentioned, has always allowed complete divorce with a right to remarry for the cause of adultery. And it is said that the form at least of an anathema of the Council of Trent was modified out of respect to difference on the part of the Greek Church (see Pothier 5. 6. 21). The papal canon law allowed a divorce *a mensâ et thoro* for six causes: (1) adultery or unnatural offences; (2) impotency; (3) cruelty; (4) infidelity; (5) entering into religion; (6) consanguinity. The Church, however, always assumed to itself the right to grant licenses for an absolute divorce; and further, by claiming the power to declare marriages null and void, though professedly this could be done only in cases where the original contract could be said to be void, it was, and is to this day, undoubtedly extended in practice to cases in which it is impossible to suppose the original contract really void, but in which a complete divorce is on other grounds desirable.

### Divorce in England.

In England the law of divorce, originally based on the canon law of Rome, underwent some, though little, permanent change at the Reformation, but was profoundly modified by the exercise of the power of the State through legislation. From the canon law was derived the principle that divorce could legally take place only by sentence of the court, and never at the will of the parties. Complete divorce has never been governed by any other principle than this; and in so far as an incomplete divorce has become practicable at the will of the parties, it has been by the intervention of civil tribunals and contrary to the law of the ecclesiastical courts. Those courts adopted as ground for divorce *a mensâ et thoro* the main grounds allowed by Roman canon law, adultery and cruelty (Ayliffe, 22; Co. Lit. 102; 1 Salk. 162; Godolphin Abridg. 495). The causes of heresy and of entering with religion, if ever they were recognized in England, ceased to exist at the Reformation.

The principles upon which the English ecclesiastical courts proceeded in divorce *a mensâ et thoro* are those which are still in force, and which (with some modification by statutory enactment) have been administered by judicial tribunals down to the present day. The courts by which the ecclesiastical law, and therefore the law of divorce, was administered were, until 1857, the courts of the various dioceses, including that of the Archbishop of Canterbury, known as the Arches Court, and that of the Archbishop of York, known as the Consistory Court of York; but by statute a suitor was prevented from taking proceedings in any court except that determined by the residence of the person against whom proceedings were taken (23 Hen. VIII. c. 9). From these courts an appeal lay to delegates appointed in each case by the Crown, until the establishment of the Judicial Committee of the Privy Council in 1836, when the appeal was given to the Crown as advised by that body.

The proof of adultery (to which Isydon in his *Book of Etymologies* gives the fanciful derivation of "*ad alterius thorum*") was not by the canon law as received in England restricted by the operation of arbitrary rules. It was never, for example, required, as by the law of Mahomet, that the act should have been actually seen by competent witnesses, nor even that the case should be based on any particular kind of proof. It was recognized that the nature of the offence almost inevitably precluded direct evidence. One rule, however, appears to have commended itself to the framers of the canon law as too general in its application not to be regarded as a principle. The mere confession of the parties was not regarded as a safe ground of conviction; and this rule was formulated by a decretal epistle of Pope Celestine III., and, following it, by the 105th of the Canons of 1604. This rule has now been abrogated; and no doubt it is wiser not to fetter the discretion of the tribunal charged with the responsibility of deciding particular cases, but experience of divorce proceedings tends to confirm the belief that this rule of the canon law was founded on an accurate appreciation of human nature.

Although, therefore, with the above exception, no strict rules of the evidence necessary to establish adultery have ever been established in the English courts, experience has indicated, and in former days judges of the ecclesiastical courts often expressed, the lines upon which such proof may be expected to proceed. It is necessary and sufficient, in general, to prove two things—first the guilty affection towards each other of the persons accused, and, secondly, an opportunity or opportunities on which, if so minded, their passion may have been gratified. It is obvious that any strong proof on either of these points renders strict proof on the other less needful; but when proof on both is afforded, the common sense of a tribunal, acting with a knowledge of human nature, may be trusted to draw the inevitable conclusion.

The definition of cruelty accepted by the ecclesiastical courts as that of the canon law is the same as that which prevails at the present time; and the view of the law taken by the House of Lords in a recent case, by which the subject is now governed (*Russell* v. *Russell*, 1897 App. Cas. 395), was expressly based on the view of cruelty taken by the authorities of the ecclesiastical law. The best definition by our older writers is probably to be found in Clarke's *Praxis* (p. 144): "Si maritus fuerit erga uxorem crudelis et ferax ac mortem comminatus et machinatus fuerit, vel eam inhumaniter verbis et verberibus tractaverit, et aliquando venenum loco potûs paraverit vel aliquod simile commiserit, propter quod sine periculo vitæ cum marito cohabitare aut obsequia conjugalia impendere non audeat . . . consimili etiam causâ competit viro contra mulierem." Lord Stowell, probably the greatest master of the civil and canon law who ever sat in an English court of justice, has in one of his most famous judgments (*Evans* v. *Evans*, 1 *Hagg. Consist.* 35) echoed the above language in words often quoted, which have constituted the standard exposition of the law to the present day. "In the older cases," he said, "of this sort which I have had the opportunity of looking into, I have observed that the danger of life, limb, or health is usually insisted as the ground upon which the court has proceeded to a separation. This doctrine has been repeatedly applied by the court in the cases which have been cited. The court has never been driven off this ground. It has always been jealous of the inconvenience of departing from it, and I have heard no one case cited in which the court has granted a divorce without proof given of a reasonable apprehension of bodily hurt. I say an apprehension, because assuredly the court is not to wait till the hurt is actually done; but the apprehension must be reasonable: it must not be an apprehension arising from an exquisite and diseased sensibility of mind. Petty vexations applied to such a constitution of mind may certainly in time wear out the animal machine, but still

they are not cases of legal relief; people must relieve themselves as well as they can by prudent resistance, by calling in the succours of religion and the consolation of friends; but the aid of courts is not to be resorted to in such cases with any effect." The risk of personal danger in cohabitation constituted, therefore, the foundation of legal cruelty. But this does not exclude such conduct as a course of persistent ill-treatment, though not amounting to personal violence, especially if such ill-treatment has in fact caused injury to health. But the person complaining must not be the author of his or her own wrong. If, accordingly, one of the spouses by his or her conduct is really the cause of the conduct complained of, recourse to the court would be had in vain, the true remedy lying in a reformation of the real cause of the disagreement.

In addition to a denial of the charge or charges, the canon law allowed three grounds of answer: (1) *Compensatio criminis*, a set-off of equal guilt or recrimination. This principle is no doubt derived from the Roman law, and it had the effect of refusing to one guilty spouse the remedy of divorce against the other although equally guilty. It was always accepted in England, although not in other countries, such as France and Scotland, which also followed the canon or civil law. In strictness, recrimination applied to a similar offence having been committed by the party charging that offence. But a recent decision of the English courts shows that a wife who had committed adultery could not bring a suit against her husband for cruelty (*Otway* v. *Otway*, 13 P. D. 141). (2) *Condonation*. If the complaining spouse has, in fact, forgiven the offence complained of, that constitutes a conditional bar to any proceedings. The main and usual evidence of such forgiveness is constituted by a renewal of marital intercourse, and it is difficult—perhaps impossible—to imagine any case in which such intercourse would not be held to establish condonation. But condonation may be proved by other acts, or by words, having regard to the circumstances of each case. Condonation is, however, always presumed to be conditional on future good behaviour, and misconduct even of a different kind revives the former offence. (3) *Connivance* constitutes a complete answer to any charge. Nor need the husband be the active agent of the misconduct of the wife. Indifference or neglect imputable to a corrupt intention are sufficient. It will be seen presently that modern statute law has gone further in this direction. It is to be added that the connivance need not be of the very act complained of, but may be of an act of a similar kind. A learned judge, recalling the classical anecdote of Mæcenas and Galba, said, "A husband is not permitted to say *non omnibus dormio.*" The ecclesiastical courts also considered themselves bound to refuse relief if there was shown to be *collusion* between the parties. In its primary and most general sense collusion was understood to be an agreement between the parties for the purpose of deceiving the court by false or fictitious evidence; for example, an agreement to commit, or appear to commit, an act of adultery. Collusion, however, is not limited to the imposing of other than genuine evidence on the court. It extends to an agreement to withhold any material evidence; and indeed is carried farther, and held to extend to any agreement which may have the effect of concealing the real and complete truth from the court (see *Churchward* v. *Churchward*, 1894, P. 161). This doctrine was of considerable importance even in the days when only divorces *a mensâ et thoro* were granted, because at that time the parties were not permitted to separate by consent. At the present day it has become, with regard to divorce *a vinculo matrimonii*, a rule of greater and of more far-reaching importance.

The canon law as accepted in England, while allowing divorces of the nature and for the causes above mentioned, actively interfered to prevent separation between husband and wife in any other manner. A suit known as a suit for restitution of conjugal rights could be brought to compel cohabitation; and on evidence of the desertion of either spouse, the court ordered a return to the matrimonial home, though it carried no further its authority as to the matrimonial relations within the home. To this suit an agreement between the parties constituted no answer. But an answer was afforded by any conduct which would have supported a decree of divorce *a mensâ et thoro*. It is a question whether, indeed, the ecclesiastical courts would not have gone farther, and refused a decree of restitution of conjugal rights on grounds which might appear adequate to justify such refusal, though not sufficient on which to ground a decree of divorce. Recently the view of the Court of Appeal and the House of Lords has given some colour to this opinion, and certainly the Court of Appeal has held, although perhaps somewhat hastily, that the effect of a modern statute has been to allow the court to refuse restitution of conjugal rights for causes falling short of what would constitute ground for divorce (*Russell* v. *Russell*, 1895, p. 315).

The ecclesiastical courts provided for the pecuniary rights of the wife by granting to her alimony during the progress of the suit, and a proper allowance after its termination in cases in which she was successful. Such payments were dependent on the pecuniary means, or *faculties*, as they were termed, of the husband, and were subject to subsequent increase or diminution in proper cases. But the ecclesiastical courts did not deal with the custody of the children of the marriage, it being probably considered that that matter could be determined by the common law rights of the father, or by the intervention of the Court of Chancery.

The canon law fixed no period of limitation, either in respect of a suit for divorce or for restitution of conjugal rights; but, as regards at least suits for divorce, any substantial delay might lead to the imputation of acquiescence or even condonation. To that extent, at least, the maxim *vigilantibus non dormientibus jura subveniunt* applied.

It is remarkable that desertion by either party to a marriage, except as giving rise to a suit for restitution, was not treated as an offence by canon law in England. It formed no ground for a suit for divorce, and constituted no answer to such a suit by way of recrimination. It might indeed deprive a husband of his remedy if it amounted to connivance, or perhaps even if it amounted only to culpable neglect.

The canon law, as administered in England, has kept clear the logical distinction which exists between dissolving a marriage and declaring it null and void. The result has been that, in England at least, the two proceedings have never been allowed to pass into one another, and a complete divorce has not been granted on pretence of a cause really one for declaring the marriage void *ab initio*. But for certain causes the courts were prepared to declare a marriage null and void on the suit of either party. There is, indeed, a distinction to be drawn between a marriage void or only voidable, though in both cases it became the subject of a similar declaration. It was void in the cases of incapacity of the parties to contract it, arising from want of proper age, or consanguinity, or from a previous marriage, or from absence of consent, a state of things which would arise if the marriage were compelled by force or induced by fraud as to the nature of the contract entered into or the personality of the parties. It is to be remarked that, in England at least, the idea of fraud as

connected with the solemnization of marriage has been kept within these narrow limits. Fraud of a different kind, such as deception as to the property or position of the husband or wife, or antecedent impurity of the wife, even if resulting in a concealed pregnancy, has not in England (though the last-mentioned cause has in other countries) been held a ground for the vitiation of a marriage contract. A marriage was voidable, and could be declared void, on the ground of physical incapacity of either spouse, the absence of intercourse between the parties after a sufficient period of opportunity being almost, if not quite, conclusive on this subject.

With regard to one cause of nullity the legislation interfered from consideration, it is said, of a case of special hardship. Before an Act of 1835 (5 & 6 Will. IV. c. 54) marriages within the prohibited degrees of consanguinity and affinity were only voidable by a decree of the court, and remained valid unless challenged during the lifetime of both the parties. But this Act, while providing that no previous marriage between persons within the prohibited degrees should be annulled by a decree of the ecclesiastical court pronounced in a suit depending at the time of the passing of the Act, went on to render all such marriages thereafter contracted in England "absolutely null and void to all interests and purposes whatever."

Another suit was allowed by the ecclesiastical courts which should be mentioned, although its bearing on divorce is indirect. This was the suit for *jactitation of marriage*, which in the case of any person falsely asserting his or her marriage to another, allowed such person to be put to perpetual silence by an order of the court. This suit, which has been of rare occurrence, although an instance of it has recently been known, does not appear to have been used for the purpose of determining the validity of a marriage. The legislature has, however, in the Legitimacy Declaration Act of 1858, provided a ready means by which the validity of marriages and the legitimacy of children can be determined, and the procedure provided has repeatedly been utilized.

It should be added, as a matter closely akin to the proceedings in the ecclesiastical courts, that the common law took cognizance of one phase of matrimonial relations by allowing an action by the husband against a paramour, known as an action for criminal conversation. In such an action a husband could recover damages estimated according to the loss he was supposed to have sustained by the seduction and loss of his wife, the punishment of the seducer not being altogether excluded from consideration. Although this action was not unfrequently (and indeed, for the purposes of a divorce, necessarily) brought, it was one which naturally was regarded with disfavour.

*Effect of the Reformation.*—Great as was the indirect effect of the Reformation upon the law of divorce in England, the direct effect was small. It might, indeed, have been supposed that the disappearance of the sacramental idea of marriage entertained by the Roman Church would have ushered in the greater freedom of divorce which had been associated with marriage regarded as a civil contract. And to some extent this was the case. It was for some time supposed that the sentences of divorce pronounced by the ecclesiastical courts acquired the effect of allowing remarriage, and such divorces were in some cases granted. In *Lord Northampton's* case in the reign of Edward VI. the delegates pronounced in favour of a second marriage after a divorce *a mensâ et thoro*. It was, however, finally decided in *Foljambe's* case, in the 44th year of Elizabeth, that a marriage validly contracted could not be dissolved for any cause. But the growing sense of the right to a complete divorce for adequate cause, when no longer any religious law to the contrary could be validly asserted, in time compelled the discovery of a remedy. The commission appointed by Henry VIII. and Edward VI. to reform the ecclesiastical law drew up the elaborate report known as the *Reformatio Legum*, and in this they recommended that divorces *a mensâ et thoro* should be abolished, and in their place complete divorce allowed for the causes of adultery, desertion, and cruelty. These proposals, however, never became law. In 1669 a private Act of Parliament was granted in the case of Lord de Roos, and this was followed by another in the case of the Duke of Norfolk in 1692. Such Acts were, however, rare until the accession of the House of Hanover, only five Acts passing before that period. Afterwards their number considerably increased. Between 1715 and 1775 there were sixty such Acts, in the next twenty-five years there were seventy-four, and between 1800 and 1850 there were ninety. In 1829 alone there were seven, and in 1830 nine.

The jurisdiction thus assumed by Parliament to grant absolute divorces was exercised with great care. The case was fully investigated before a committee of the House of Lords, and not only was the substance of justice so secured, but the House of Lords further required that application to Parliament should be preceded by a successful suit in the ecclesiastical courts resulting in a decree of divorce *a mensâ et thoro*, and in the case of a husband being the applicant, a successful action at common law and the recovery of damages against the paramour. In this way, and also, if needful, on its own initiative, the House of Lords provided that there should be no connivance or collusion. Care was also taken that a proper allowance was secured to the wife in cases in which she was not the offending party. This procedure is still pursued in the case of Irish divorces.

It is obvious, however, that the necessity for costly proceedings before the Houses of Parliament imposed great hardship on the mass of the population, and there can be little doubt that this hardship was deeply felt. Repeated proposals were made to Parliament with a view to reform of the law, and more than one commission reported on the subject. It is said that the final impetus was given by an address to a prisoner by Mr Justice Maule. The prisoner's wife had deserted him with her paramour, and he married again during her lifetime. He was indicted for bigamy, and convicted, and Mr Justice Maule sentenced him in the following words:—"Prisoner at the bar: You have been convicted of the offence of bigamy, that is to say, of marrying a woman while you had a wife still alive, though it is true she has deserted you and is living in adultery with another man. You have, therefore, committed a crime against the laws of your country, and you have also acted under a very serious misapprehension of the course which you ought to have pursued. You should have gone to the ecclesiastical court and there obtained against your wife a decree *a mensâ et thoro*. You should then have brought an action in the courts of common law and recovered, as no doubt you would have recovered, damages against your wife's paramour. Armed with these decrees, you should have approached the legislature and obtained an Act of Parliament which would have rendered you free and legally competent to marry the person whom you have taken on yourself to marry with no such sanction. It is quite true that these proceedings would have cost you many hundreds of pounds, whereas you probably have not as many pence. But the law knows no distinction between rich and poor. The sentence of the court upon you, therefore, is that you be imprisoned for one day, which period has already been exceeded, as you have been in custody since the commencement of the assizes." The grave irony of the learned judge was felt to

represent truly a state of things well-nigh intolerable, and a reform in the law of divorce was felt to be inevitable. The hour and the man came in 1857, the man in the person of Sir Richard Bethell, then Attorney-General.

*The Act of 1857.*—Probably few measures have been conceived with such consummate skill and knowledge, and few conducted through Parliament with such dexterity and determination. The leading opponent of the measure was Mr Gladstone, backed by the zeal of the High Church party and inspired by his own matchless subtlety and resource. But the contest proved to be unequal, and after debates in which every line, almost every word, of the measure was hotly contested, especially in the House of Commons, the measure emerged substantially as it had been introduced. Not the least part of the merit and success of the Act of 1857 is due to the skill which while effecting a great social change, did so with the smallest possible amount of innovation. The Act embodied two main principles: 1. The constitution of a lay court for the administration of all matters connected with divorce. 2. The transfer to that court, with as little change as possible, of the powers exercised in matrimonial matters by (*a*) the House of Lords, (*b*) the ecclesiastical courts, (*c*) the courts of common law.

*The Constitution of the Court.*—The new court, termed "The Court for Divorce and Matrimonial Causes," was constituted by the Lord Chancellor, the chiefs and the senior puisne judges of the three courts of common law, and the judge of the Court of Probate (which was also established in 1857), but the functions of the court were practically entrusted to the judge of the Court of Probate, termed the "Judge Ordinary," who thus in matters of probate and divorce became the representative of the former ecclesiastical jurisdiction. The Judge Ordinary was empowered either to sit alone or with one or more of the other judges to constitute a full court. The parties to a suit obtained the right of trial by jury of all disputed questions of fact; and the rules of evidence of the common law courts were made to apply. An appeal to the full court was given in all matters, which the Judge Ordinary was enabled to hear sitting alone.

1. To this court was transferred all the powers of the ecclesiastical courts with regard to suits for divorce *a mensâ et thoro*, to which the name was given of suits for "judicial separation," nullity, restitution of conjugal rights, and jactitation of marriage, and in all such proceedings it was expressly enacted (sec. 22) that the court should act on principles and rules as nearly as possible conformable to the principles and rules of the ecclesiastical courts. Judicial separation could be obtained by either husband or wife for adultery, or cruelty, or desertion continued for two or more years.

2. There were also transferred to the court powers equivalent to those exercised by the legislature in granting absolute divorce. The husband could obtain a divorce for adultery, the wife could obtain a divore for adultery coupled with cruelty or desertion for two or more years, and also for incestuous or bigamous adultery, or rape, or unnatural offences. The same conditions as had been required by the legislature were insisted on. A petition for dissolution (sec. 30) was to be dismissed in case of connivance, condonation, or collusion; and further, the court had power, though it was not compelled, to dismiss such petition if the petitioner had been guilty of adultery, or if there had been unreasonable delay in presenting or prosecuting the petition, or if the petitioner had been guilty of cruelty or desertion without reasonable excuse, or of wilful neglect or misconduct conducing to the adultery. The exercise of these discretionary powers of the court, just and valuable as they undoubtedly are, has been attended with some difficulty. But the view of the legislature has on the whole been understood to be that the adultery of a petitioner should not constitute a bar to his or her proceeding, if it has been caused by the misconduct of the respondent, and that cruelty should not constitute such a bar unless it has caused or contributed to the misconduct of the respondent. But the court, while regarding its powers as these of a judicial and not an arbitrary discretion, has declined to fetter itself by any fixed rule of interpretation or practice.

It is to be observed that this Act assigned a new force to desertion. The ecclesiastical law regarded it only as suggestive of connivance or culpable neglect. But the Act of 1857 made it (1) a ground of judicial separation if continued for two years, (2) a ground in part of dissolution of marriage if continued for the same period, (3) a bar, in the discretion of the Court, to a petition for dissolution, though it was not made in a similar way any bar to a suit for judicial separation. It is also to be observed that the Act was confined to causes of divorce recognized by the ecclesiastical law as administered in England. It did not either extend the causes of a suit for nullity by adding such grounds as antenuptial incontinence, even if accompanied with pregnancy, nor did it borrow from the civil law of Rome either lunacy or crime as grounds for divorce.

Much comment has been made on the different grounds on which divorce is allowed to a husband and to a wife,—it being necessary to prove infidelity in both cases, but a wife being compelled to show either an aggravation of that offence or an addition to it. Opinions probably will always differ whether the two sexes should be placed on an equality in this respect, abstract justice being invoked, and the idea of marriage as a mere contract pointing in one direction, and social considerations in the other. But the reason of the legislature for making the distinction is clear. It is that the wife is entitled to an absolute divorce only if her reconciliation with her husband is neither to be expected nor desired. This was no doubt the view taken by the House of Lords. In 1801 a Mrs Addison claimed an absolute divorce on the ground of her husband's incest with her sister. The matter was long debated, but Lord Thurlow, who appeared in the House of Lords for the last time in order to support the Bill, turned the scale by arguing that it was improper that the wife should under such circumstances return to her husband (see Campbell, *Lives of the Chancellors*, vii. 145). "Why do you," he said, "grant to the husband a divorce for the adultery of the wife? Because he ought not to forgive her, and separation is inevitable. Where the wife cannot forgive, and separation is inevitable by reason of the crime of the husband, the wife is entitled to the like remedy."

The Act (sec. 32) provided, in case of dissolution, for maintenance of the wife by the husband on principles similar to those recognized by the ecclesiastical courts, and (sec. 45) for the settlement of the property of a guilty wife on her husband or children; but this enactment was imperfect, as provision was made only for a settlement and not for payment of an allowance, and none was made for altering settlements made in view or in consequence of a marriage. The Act (sec. 35) provides also in all divorce proceedings, and also in those of nullity, for provision for the custody, maintenance, and education of children by the court: provisions of great value, which were unfortunately for some time limited by an erroneous view of the court that the age of the children to which such provisions applied should be considered limited to sixteen. The Act of 1857 also transferred to the new court the powers exercised by the common law courts in the action for

criminal conversation. It was made obligatory to join an alleged adulterer in the suit, and damages (sec. 33) might be claimed against him, and he might be ordered to pay the costs of the proceedings (sec. 34). The latter provision, however, has been considerably curtailed by a recent decision of the Court of Appeal.

The Act of 1857 in one respect went beyond a transfer of the powers exercised by the ecclesiastical courts or the legislature. It provided (sec. 21) that a wife deserted by her husband might apply to a magistrate in petty sessions and obtain an order which had the effect of protecting her earnings and property, and during the currency of such order of protection a wife was to be in the same position as if she had obtained an order for judicial separation. The effect of this section appears to have been small; but further legislation in 1895 has afforded a cheap and speedy remedy to all classes of the community.

The framers of the Act of 1857 were careful to avoid offending the scruples of clergymen who disapproved of the complete dissolution of marriage by a lay court. It was provided (secs. 57 and 58) that no clergyman should be compelled to solemnize the marriage of any person whose former marriage had been dissolved on the ground of his or her adultery, but should permit any other clergyman to solemnize the marriage in any church or chapel in which the parties were entitled to be married. It is to be feared that this concession, ample as it appears, has not allayed conscientious objections, which are perhaps from their nature insuperable. The Act made no provision as to the name to be borne by a wife after a divorce; and this omission has led to litigation in the case of a peer's wife.

*Modifications of the Act of 1857.*—Subsequent legislation has made good many of the defects of the Act of 1857. In 1859 power was given to the court, after a decree of dissolution or of nullity of marriage, to inquire into the existence of ante- and post-nuptial settlements, and to make orders with respect to the property settled either for the benefit of children of the marriage or their parents; and a subsequent Act (41 & 42 Vict. c. 19, s. 3) removed a doubt which was entertained whether these powers could be exercised if there were no children of the marriage. In 1860 a very important change was made, having for its object a practical mode of preventing divorces in cases of connivance and collusion or of misconduct of the petitioner. It was provided that a claim of dissolution (a provision afterwards extended to decrees of nullity) should in the first instance be a decree *nisi*, which should not be made absolute until the expiration of a period then fixed at not less than three, but by subsequent legislation enlarged to not less than six, months. During the interval which elapsed between the decree *nisi* and such decree being made absolute, power was given to any person to intervene in the suit and show cause why the decree should not be made absolute, by reason of the same having been obtained by collusion, or by reason of material facts not brought before the court; and it was also provided that, at any time before the decree was made absolute, the Queen's Proctor, if led to suspect that the parties were acting in collusion for the purpose of obtaining a divorce contrary to the justice of the case, might under the direction of the Attorney-General intervene and allege such case of collusion. This enactment (extended in the year 1873 to suits for nullity) was ill drawn and unskilfully conceived. The power given to any person whomsoever to intervene is no doubt too wide, and practically has had little or no useful effect as employed by friends or enemies of parties to a suit. The limitation in terms of the express power of the Queen's Proctor to intervene to cases of collusion was undoubtedly too narrow. But the Queen's Proctor, or the official by whom that officer was afterwards represented, has in practice availed himself of the general authority given to any person to show cause why a decree *nisi* should not be made absolute, and has thus been enabled to render such important service to the administration of justice that it is difficult to imagine the due execution of the law of divorce by a court without such assistance. In 1866 power was given to the court to order an allowance to be paid by a guilty husband to a wife on a dissolution of marriage. This Act also can hardly be considered to have been drawn with sufficient care, inasmuch as while it provides that if the husband's means diminish, the allowance may be diminished or suspended, it makes no corresponding provision for increase of the allowance if the husband's means increase; nor, apparently, does it permit of an allowance in addition to, but only in substitution for, a settlement. The Act makes no provision for allowance to a guilty wife, and it certainly is a serious defect that the power to grant an allowance does not extend to cases of nullity. In 1868 an appeal to the House of Lords was given in cases of decree for dissolution or nullity of marriage.

The great changes effected by the Judicature Acts included the Court for Divorce and Matrimonial Causes. Under their operation a division of the High Court of Justice was constituted, under the designation of the Probate Division and Admiralty Division, to which was assigned that class of legal administration governed mainly by the principles and practice of the canon and civil law. The division consists of a President, and a Justice of the High Court, with registrars representing each branch of the jurisdiction. Appeals lie to the Court of Appeal, and thence to the House of Lords.

In 1884 the legislature interfered to prevent imprisonment being the result of disobedience to an order for restitution of conjugal rights. That mode of enforcing the order of the court was abolished, and the matter was left to a proper adjustment of the pecuniary relations of the husband and wife; and a respondent disobeying such an order was held to be guilty of desertion without reasonable cause, such desertion having further given to it a similar effect to that assigned to desertion for two years or upwards. The effect of this provision has been that the suit for restitution of conjugal rights is most frequently brought for the purpose of shortening the time within which a wife can obtain a decree for dissolution of marriage.

Proceedings in the Divorce Court have shown the improvement in the law of evidence which has been effected with regard to other legal proceedings. The Act of 1857 made an inroad on the former law, which prohibited evidence being given by parties interested in the proceedings, by allowing a petitioner (sec. 43) to be called and examined by order of the court, absolving such petitioner, however, from the necessity of answering any question tending to show that he or she had been guilty of adultery. In the next year power was given to the court to dismiss any person, with whom a party to the suit was alleged to have committed adultery, from the suit if there should not appear to be sufficient evidence against him or her, the object being to allow such person to give evidence; and in 1859 it was provided that, on a petition by a wife for a divorce on the grounds of cruelty or desertion with adultery, the husband and wife were rendered competent and compellable witnesses as to the cruelty or desertion. A few years later, however, in 1869, the subject was finally dealt with by repealing all previous rules which limited the powers to give evidence on questions of adultery, with the safeguard that no witness in any proceeding can be asked or bound to

answer any question tending to show that he or she has been guilty of adultery, unless in the same proceeding such witness shall have given evidence in disproof of his or her alleged adultery. It has been held that the principles of these enactments apply to interrogatories as well as to evidence given in court.

It is a most remarkable omission in the Act of 1857, especially when we remember the high legal authority from whom it proceeded, that the Act nowhere defines the class of persons with regard to whom the jurisdiction of the court should be exercised. This omission has given rise to a misapprehension of the law which, though now set at rest, prevailed for a considerable period, and has undoubtedly led to the granting of divorce in several cases in which it could not legally be given. It was supposed that the court could grant a dissolution of marriage to all persons who had anything more than a casual and fleeting residence within the jurisdiction of the court; and this view, although its correctness was doubted by Lord Penzance, the judge of the Divorce Court, was upheld by a majority of the judges of the Court of Appeal in the case of *Niboyet* v. *Niboyet* (4 P. D. 1). It was supposed that such residence gave what was termed a matrimonial domicile. But this view was undoubtedly erroneous as regards dissolution of marriage, although probably correct as regards judicial separation, and the true view is no doubt that indicated with great learning and ability by Lord Watson in a judgment given by him in the Privy Council in the case of *Le Mesurier* v. *Le Mesurier* (1895, App. Cas. 517), that the only true test of jurisdiction for a decree of divorce altering the status of the parties to a marriage is to be found in the domicile of the spouses—that is to say, of the husband, as the domicile of a wife follows that of her husband—at the time of the divorce. The legal definition of domicile is the subject of elaborate rules. It is sufficient to say here that domicile means a person's permanent home, the place at which he resides, with no intention of making his home elsewhere, and if he leaves it, with the intention of returning to it.

It is now also clearly recognized as the law of England that the English courts will not recognize a divorce purporting to be made by a foreign tribunal with regard to persons domiciled in England. For a considerable time doubt appears to have clouded the law on this subject. In a famous case known as *Lolley's* case, decided in 1812, the judges of England (the point arose in connexion with a criminal charge) unanimously held "that no sentence or act of any foreign country or any state could dissolve an English marriage *a vinculo matrimonii* for grounds on which it was not liable to be dissolved *a vinculo matrimonii* in England." This case has been frequently understood as deciding that a marriage celebrated in England cannot be dissolved elsewhere, and on this point the courts of Scotland differ from the view supposed to be taken by the English judges. But the matter has been fully explained in one of the most masterly of Lord Hannen's judgments (*Harvey* v. *Fairnie*, 5 P. D. 154), afterwards upheld by the House of Lords in 1882 (8 App. Cas. 43); and it is now clear that while the parties are domiciled in this country no decree of any foreign court dissolving their marriage will be recognized here, unless it proceed on the grounds on which a divorce may be obtained in this country, and even the exception just mentioned appears to rest rather on reasoning and principle than on the authority of any decided case. This principle has received the highest sanction in a recent prosecution of Earl Russell for bigamy before the House of Lords.

*Summary Proceedings for Separation.*—The legislature has sought to extend the relief afforded by the courts in matrimonial causes by a procedure fairly to be considered within the reach of all classes. In 1895 an Act was passed which re-enacted in an improved form the provisions of an Act of 1878 of similar effect. By the Act of 1895 power was given to a married woman whose husband (1) has been guilty of an aggravated assault upon her within the Offences against the Person Act, 1861, or (2) convicted on indictment of an assault on her and sentenced to pay a fine of more than £5 or to imprisonment for more than two months, or (3) shall have deserted her, or (4) been guilty of persistent cruelty to her or wilful neglect to maintain her or her infant children, and by such cruelty or neglect shall have caused her to leave and live apart from him, to apply to a court of summary jurisdiction and to obtain an order containing all or any of the following provisions: (1) that the applicant be not forced to cohabit with her husband, (2) that the applicant have the custody of any children under sixteen years of age, (3) that the husband pay to her an allowance not exceeding £2 a week. The Act provides that no married woman guilty of adultery should be granted relief, but with the very important proviso, altering as it does the rule of the common law, that the husband has not conduced or connived at, or by wilful neglect or misconduct conduced to, such adultery. The provisions of this Act have been largely put in force, and no doubt to the great advantage of the poorer classes of the community. It will be observed that the Act is unilateral, and affords no relief to a husband against a wife; and the complaint is often heard that no misconduct of the wife, except adultery, relieves the husband from the necessity of maintaining her and allowing her to share his home, unless he can obtain access to the High Court.

*Separation Deeds.*—Although nothing in the development of the law of divorce has tended to give to married persons the right absolutely to dissolve their marriage by consent, and, on the contrary, any such agreement would be held to be strong evidence of collusion, the view of the Church expressed in the ecclesiastical law has been entirely departed from as regards agreements for separation. Such agreements were embodied in deeds, and usually contained mutual covenants not to sue in the ecclesiastical courts for restitution of conjugal rights. The ecclesiastical courts, however, wholly disregarded such agreements, and considered them as affording no answer to a suit for restitution of conjugal rights. For a considerable period the Court of Chancery refused to enforce the covenant in such deeds by restraining the parties from proceeding to the ecclesiastical courts. But at last a memorable judgment of Lord Westbury asserted the right (*Hunt* v. *Hunt*, 4 De G. F. & J. 221; see also *Marshall* v. *Marshall*, 5 P. D. 19) of the Court of Chancery to maintain the claim of good faith in this as in other cases, and restrained a petitioner from suing in the ecclesiastical court contrary to his covenant. Thereafter these deeds became common, and no doubt often afford a solution of matrimonial difficulties of very great value. When the courts of the country became united under the Judicature Acts, it became practicable to set up in the Divorce Division a separation deed in answer to a suit for restitution of conjugal rights without the necessity of recourse to any other tribunal.

*Statistics.*—The statistics of divorce in England have for some years been regularly published in the volumes of judicial statistics published annually by the Home Office—that published in 1901 bringing the figures down to 1899.

The number of petitions for divorce (including in the term both divorce *a mensâ et thoro* and divorce *a*

*vinculo*) for the years from 1858 to 1899 inclusive are as follows:—

| | | | | | |
|---|---|---|---|---|---|
| 1858 | 326 | 1872 | 374 | 1886 | 708 |
| 1859 | 291 | 1873 | 416 | 1887 | 662 |
| 1860 | 272 | 1874 | 469 | 1888 | 680 |
| 1861 | 236 | 1875 | 451 | 1889 | 654 |
| 1862 | 248 | 1876 | 536 | 1890 | 644 |
| 1863 | 298 | 1877 | 551 | 1891 | 632 |
| 1864 | 297 | 1878 | 632 | 1892 | 629 |
| 1865 | 284 | 1879 | 555 | 1893 | 645 |
| 1866 | 279 | 1880 | 615 | 1894 | 652 |
| 1867 | 294 | 1881 | 589 | 1895 | 683 |
| 1868 | 303 | 1882 | 481 | 1896 | 772 |
| 1869 | 351 | 1883 | 561 | 1897 | 781 |
| 1870 | 351 | 1884 | 647 | 1898 | 750 |
| 1871 | 384 | 1885 | 541 | 1899 | 727 |

It is probably impossible to account for the variations which the above table discloses. It was no doubt natural that the year immediately succeeding the passing of the Act which originated facilities for divorces *a vinculo* should exhibit a larger number of divorces than its successors for a considerable period. But there does not appear to be any adequate cause for the comparative increase which seems to have prevailed in the decade between 1878 and 1888, unless it be found in the increase of marriages which culminated in 1873 and 1883, falling after each of those years. The number of marriages again rose high in 1891 and 1892, and this may account for the increased number of divorces in 1896 and the following years. But it may certainly be said with confidence that as compared with the growth of population the number of divorces in England, especially in recent years, shows no alarming increase.

The total number of petitions in matrimonial causes presented by husbands exceed those presented by wives, but in no marked degree. This excess would seem to be due to the fact that the larger number of petitions for dissolution presented by husbands, owing no doubt to the difference in the law affecting the two sexes, is not entirely counterbalanced by the much larger number of petitions for judicial separation presented by wives. The following figures for the years 1895 to 1899 inclusive may be taken as typical:—

| | 1895. | 1896. | 1897. | 1898. | 1899. |
|---|---|---|---|---|---|
| Petitions for Dissolution— | | | | | |
| Presented by husbands | 353 | 393 | 414 | 401 | 383 |
| Presented by wives | 220 | 280 | 269 | 243 | 262 |
| Petitions for Judicial Separation— | | | | | |
| Presented by husbands | 4 | 3 | 2 | 4 | 4 |
| Presented by wives | 106 | 96 | 96 | 102 | 78 |
| Total: Presented by husbands | 357 | 396 | 416 | 405 | 387 |
| Presented by wives | 326 | 376 | 365 | 345 | 340 |

Speaking generally, it may be said that about 70 per cent. of the petitions presented are successful and result in decrees. This percentage has tended to rise in recent years.

Attempts have been made to ascertain the classes which supply the petitioners for divorce, but this cannot be done with such certainty as to warrant any but the most general conclusions. It may, however, safely be said that while all classes, professions, and occupations are represented, it is certainly not those highest in the scale that are the largest contributors. The principles of the Act of 1857 have beyond question been justified by the relief required by and afforded to the poorer members of the community.

### Other European Countries.

We may now turn to the law of divorce as administered in the other countries of the modern world. On the main question whether marriage is to be considered indissoluble they will be found to range themselves on one side or the other according to the influence upon them of the Church of Rome and its canon law.

In *Scotland* it has long been the law that marriage can be dissolved at the instance of either party by judicial sentence on the grounds of adultery or of desertion, termed non-adherence, and the spouses could in such case remarry, except with the person with whom the adultery was committed. A divorce *a mensâ et thoro* could also be granted for cruelty. By an Act of Parliament (11 Geo. IV. and 1 Will. IV. c. 69) the jurisdiction in divorce was transferred from a body of commissaries to the Court of Session.

By the law of *Holland* complete divorce could be granted by judicial sentence on the grounds of adultery or of wilful and malicious desertion, to which were added unnatural offences and imprisonment for life, and such divorce gave the power of remarriage, except with the person with whom adultery was proved to have been committed, but there would seem to be a doubt whether this power extended to the guilty party (Voet, *de Divortiis*, lit. 24 tit. 2). Divorce *a mensâ et thoro* could be granted on the grounds allowed by the canon law.

The Code of *Prussia* of 1794 contained elaborate provisions which gave great facility of divorce. A complete divorce could be obtained by judicial sentence for the following causes: (1) Adultery or unnatural offences; and adultery by a husband formed no bar to his obtaining a divorce against his wife for adultery; and even an illicit intimacy, from which a presumption of adultery might arise, was held sufficient for a divorce. (2) Wilful desertion. (3) Obstinate refusal of the rights of marriage, which was considered as equivalent to desertion. (4) Incapacity to perform the duties of marriage, even if arising subsequent to the marriage; and the same effect was assigned to other incurable bodily defects that excited disgust and horror. (5) Lunacy, if after a year there was no reasonable hope of recovery. (6) An attempt on the life of one spouse by the other, or gross and unlawful attack on the honour or personal liberty. (7) Incompatibility of temper and quarrelsome disposition, if rising to the height of endangering life or health. (8) Opprobrious crime for which either spouse has suffered imprisonment, or a knowingly false accusation of such crime by one spouse of the other. (9) If either spouse by unlawful transactions endangers the life, honour, office, or trade of the other, or commences an ignominious employment. (10) Change of religion. In addition to these causes, marriages, when there were no children, could be dissolved by mutual consent if there be no reason to suspect levity, precipitation, or compulsion; and a judge had also power to dissolve a marriage in cases in which a strongly-rooted dislike appeared to him to exist. In all cases of divorce, but sometimes subject to the necessity of obtaining a license, remarriage was permissible (see Burge, *Commentaries on Colonial and Foreign Law*, vol. i. 649).

By the law of *Denmark*, according to the Code of King Christian the Fifth, complete divorce could be obtained for incest; for leprosy, whether contracted before or after marriage; for transportation for crime or flight from justice, after three years, though not for crime itself; and for exile not arising from crime, after seven years.

In *Sweden* complete divorce is granted by judicial sentence for adultery, and in *Russia* for that cause and also for incompatibility of temper (Ayliffe, Par. 49). On the other hand, in *Spain* marriage is indissoluble, and the ecclesiastical courts have retained their exclusive cognizance of matrimonial causes. In *Italy* certain articles of the Civil Code deal with separation, voluntary and judicial, but divorce is not allowed in any form.

In *France* the law of divorce has had a chequered history. Before the Revolution the Roman canon law prevailed, marriage was considered indissoluble, and only divorce *a mensâ et thoro*, known as *la separation d'habitation*, was permitted; though it would appear that in the earliest age of the monarchy divorce *a vinculo matrimonii* was allowed. *La separation d'habitation* was granted at the instance of a wife for cruelty by her husband or false accusation of a capital crime, or for habitual treatment with contempt before the inmates of the house; but a wife could not obtain a separation for adultery by her husband, although he had his remedy in case of adultery by his wife. In every case the sentence of a judicial tribunal, which took precautions against collusion, was necessary. But the Revolution may be said to have swept away marriage among the institutions which it overwhelmed, and by the law of 20th September 1792 so great facility was given for divorce *a vinculo matrimonii* as practically to terminate the obligations of marriage. A reaction came with the Code Napoléon, yet even under that system of law divorce remained comparatively easy. Mutual consent, expressed in the manner and continued for a period specified by the law, was cause for a divorce (the principle of the Roman law being adopted on this point), but such consent could not take place unless the husband was twenty-five years of age and the wife twenty-one, unless they had been married for two years, nor after twenty years of marriage, nor after the wife had completed her forty-fifth year; and further, the approval of the parents of both parties was required. In case of divorce by consent, the law required that a proper agreement should be made for the maintenance of the wife and the custody of the children. A husband could obtain a divorce *a vinculo matrimonii* for adultery, but the wife had no such power unless the husband had brought his mistress to the home. Both husband and wife could claim divorce on the ground of outrage, or grievous bodily injury, or condemnation for an infamous crime. If the divorce was for adultery, the erring party could not marry the partner of his or her guilt. A divorce *a mensâ et thoro* could be obtained on the same grounds as a divorce *a vinculo*, but not by mutual consent; and if the divorce *a mensâ et thoro* continued in force for three years, the defendant party could claim a divorce *a vinculo*. On the restoration of royalty in 1816 divorce *a vinculo* was abolished, and pending suits for divorce *a vinculo* were converted into suits for separation only.

Divorce in France, after the repeal of the provisions respecting it in the Code Napoléon in 1816, was re-enacted by a law of 27th July 1884, the provisions of which were simplified by a further law of April 20, 1886. But a wide departure was made by these laws from the terms of the Code Napoléon. Divorce by consent disappeared, and the following became the causes for which divorce was allowed: (1) Adultery by either party to the marriage at the suit of the other, without, in the case of adultery by the husband, the aggravation of introduction of the concubine into the home required by the Code; (2) violence (*excés*) or cruelty (*sévices*); (3) *injures graves*; and (4) *peine afflictive et infamante*. *Excés* is defined by Locié as "a generic expression comprising all acts tending to compromise the safety of the person, without distinction as to their object or motive, premeditation as well as furious anger, attempts upon life as well as serious woundings." *Sévices* are acts of ill-treatment less grave in character, which, while not endangering life, render existence in common intolerable (Kelly's *French Law of Marriage*, p. 122). *Injures graves*, as to which the courts have considered themselves entitled to exercise a wide discretion, have been defined as acts, writings, or words which reflect upon the honour or the reputation of the party against whom they are directed. The courts have held that retraction at the trial does not relieve the party from the consequences of an *injure grave*, and that publicity is an aggravating but not a necessary element. A letter from one spouse to the other may constitute an *injure*, and the courts have further held themselves at liberty to consider letters written after divorce proceedings have been commenced. *Injures graves* have also been considered to include material injuries, and among these have been classed habitual and groundless refusal of matrimonial rights, communication of disease, and refusal to consent to a religious cèremony of marriage. Habitual but not occasional drunkenness has also been held to fall within the definition of an *injure grave*. *Peine afflictive et infamante* signifies a legal punishment involving corporal confinement and moral degradation.[1]

In addition to its recognition of full divorce, the French law recognizes separation of two kinds, one *séparation de biens* and the other *séparation de corps*. The effect of *séparation de biens* is merely to put an end to the community of goods between the spouses. It necessarily follows, but may be decreed independently of *séparation de corps*. The grounds of *séparation de corps* are the same as those for a divorce; and if a *séparation de corps* has existed for three years, it may be turned into a divorce upon the application of either party to the court.

Until 1893 a wife *séparée de corps* obtained only the capacity attaching to a concomitant *séparation de biens;* that is to say, she recovered the enjoyment and management of her separate property, but could not deal with real property, nor take legal proceedings, without the sanction of her husband or of the court. But by a law of 6th February 1893 a wife *séparée de corps* obtains "the full exercise of her civil capacity, so that she shall not need to resort to the authority of her husband or of the court." In case of reconciliation, the wife returns to the limited capacity of a wife *séparée de biens*, and after the prescribed notification of such change of status it becomes binding on third persons.

The provisions of French law with regard to the custody of the children of a dissolved marriage, and with regard to property, do not differ materially from those prescribed by the English Acts. The custody of children is given to the party who has obtained the divorce, unless the court, on the application of the family, or the *ministère public*, consider it better, in the interests of the children, that custody should be given to the other party or a third person; but in every case the right of both father and mother to supervise the maintenance and education of the children, and their liability to contribute to their support, are continued.

The law in France as to property on a divorce has been accurately stated as follows:—

> "Divorce in France effects a dissolution of the matrimonial *régime* of property as well as of the marriage itself. The decree appoints a notary, who is charged with the settlement of the pecuniary interests of the parties. By a stereotyped form of procedure the appointment is made invariably for the purpose of liquidating *la communauté ayant existé entre les epoux*, irrespective of whether the *régime* really was that of community or another. In the case of aliens, therefore, married under the rule of separate property, it is necessary carefully to set this out in the notarial deed of liquidation, in order to

[1] It is interesting to observe how, according to the latest decision of the House of Lords above referred to, cruelty, according to English law, includes some but not others of the forms of injury for which, under the term of *injures graves*, the French law affords a remedy. It may well be doubted whether the view taken by the minority of the peers, which would have included in the definition of cruelty all, or nearly all, of that which the French law deems either *sévices* or *injures graves*, would not have better satisfied both the principles of English jurisprudence and the feelings of modern life.

defeat the presumption which might be raised by the wording of the decree that a community really did exist. The party against whom the divorce has been pronounced loses the benefit of all settlements made upon him or her by the other party, either by the marriage contract or since the marriage. On the other hand, the party in whose favour the divorce has been pronounced preserves the benefit of all settlements made in his or her favour by the unsuccessful party. If no such settlements were made, or if those made appear inadequate to ensure the subsistence of the successful party, the court may grant him or her permanent alimony out of the property of the other party, not to exceed one-third of the income, and revocable in case it ceases to be necessary" (Kelly, p. 130).

On a divorce both parties are at liberty to remarry, the husband at once, the wife after an interval of ten months. A divorced husband may remarry his divorced wife, but if he does so, he cannot be again divorced, except on the ground of a sentence to a *peine afflictive et infamante* passed on one of them since their remarriage. There is, however, this limitation on the power of remarriage of divorced persons, that the party to the marriage against whom the decree has been pronounced is not allowed to marry the person with whom his or her guilt has been established. Such person, however, has no such rights as are recognized in him or her according to English law, and cannot take any part in the proceedings. But his or her name is referred to in the proceedings only by an initial; and French law goes even further in the avoidance of publicity, inasmuch as the publication of divorce proceedings in the press is forbidden, under heavy penalties.

By a law of 6th February 1893 French jurisprudence, more complete at least, and perhaps wiser, than English, dealt with a matter previously in controversy, and decided that after a divorce the wife shall resume her maiden name, and may not continue to use the name of her divorced husband; nor may the husband, for business or other purposes, continue to use the name of his wife.

By the law of 1886 the special procedure in divorce previously in force under the Code and under the law of 1884 was abolished, and it was provided that matrimonial causes should be tried according to the ordinary rules of procedure. The action therefore, when brought, follows the methods of procedure common to other civil proceedings. But there still remain certain necessary preliminaries to an action of divorce. A petition must be presented by a petitioner in person to the President of the court sitting in chambers, with the object of a reconciliation being effected. This is known as the *première comparation.* If the petitioner still determines to proceed, there follows the *seconde comparation*, on which occasion both parties appear before the President. If the President fails to effect a reconciliation, he makes an order permitting the petitioner to proceed, and deals with the matters necessary to be dealt with *pendente lite*, such matters being (1) separate residence, (2) alimony, (3) possession of personal effects, (4) custody of children. As regards residence, the wife is compelled to adhere during the proceedings to the residence assigned to her, but no similar restriction is placed on the husband. Alimony *pendente lite* is in the discretion of the court, having regard to the means of the parties, and includes a proper provision for costs. As regards the custody of children, the Code and the law of 1884 gave it to the husband, unless the court otherwise orders, but the law of 1886 leaves the matter wholly in the discretion of the court.

There are certain technical rules of evidence on the trial of a divorce action. It is a general principle of the French law of evidence that documentary evidence is the best evidence, and oral testimony only secondary. In divorce cases adultery *flagrante delicto* can be proved by the official certificate of the commissary of police. Letters between the husband and wife are admissible in evidence. As to letters between the parties and third persons, the law, which has been doubtful, now appears to be that the wife may produce only such letters from third parties to her husband as have come into her possession accidentally, and without any ruse or artifice on her part; but the husband may put in evidence any letters written to or by his wife which he has obtained by any, short of criminal, means. If the documents put in evidence are not sufficient to satisfy the court, there follows an investigation by means of witnesses, termed an *enquête.* A schedule of allegations is drawn up, and a judge, termed a *juge-commissaire*, is specially appointed to conduct the inquiry. Relatives and servants, though not competent witnesses in ordinary civil actions, are so in divorce proceedings. Cross petitions may be entered; the substantiation of a cross petition, however, does not have the effect, in some cases given to it by English law, of barring a divorce, but a divorce may be, and often is, granted in favour of and against both parties *pour torts reciproques.* When a case comes on for trial, it is in the power of the court to order an adjournment for a period not exceeding six months, which is termed a *temps d'epreuve*, in order to afford an opportunity for reconciliation. It is said, however, that this power is seldom exercised. An appeal may be brought against a decree of divorce within two months; and a decree made on appeal is subject to revision by the Court of Cassation within two months. Both references to the Court of Appeal and the Court of Cassation operate as a stay of execution. A decree must, by the law of 1886, be transcribed on the register of marriages within two months from its date, and failing this transcription, the decree is void. The transcription must be made at the place of celebration of the marriage, or, if the parties are married abroad, at the place where the parties were last domiciled in France. If the parties, after having married abroad, return to France, it has been provided, by a circular of the *Procureur de la République* in 1887, that the transcription may be made at the place of their actual domicile at the time of action brought, a rule which has been held to apply to the divorce of aliens in France. The effect of transcription does not relate back to the date of the decree.

Opinions may differ as to the relative merits of the English and French law relating to divorce. But it cannot be denied that the French law presents a singularly complete and well-considered system, and one which, obviously with the English system in view, has endeavoured to graft on it provisions supplementing its omissions, and modifying certain of its terms in accordance with the light afforded by experience and the changed feelings of the modern world. The effect of the laws of 1884 and 1886 in France has been great. During the five years from 1884 to 1888 the courts granted divorces in 21,064 cases, rejecting applications for divorce in 1524. In addition, there were 12,242 applications for judicial separation, of which 10,739 were granted. A distinguished French writer, the author of a work of singular completeness and accuracy on the judicial system of Great Britain, has compared these figures with the corresponding result of the English Act of 1857. His conclusion is expressed in these words: "On voit qu'en cinq années nos tribunaux ont prononcé trois fois plus de divorces que la haute Cour d'Angleterre n'en a prononcé en trente ans. Je n'insiste pas sur les conclusions morales à tirer de ce rapprochement" (Comte de Franqueville, *Le Système Judiciare de la Grande Bretagne*, ii. p. 171). It is, however, practically impossible to compare the number of divorces in France and in England with exact justice, because, as will have been seen above, the causes of divorce in France materially exceed those recognized by English law; and the absence in France of any official performing

the functions assigned to the King's Proctor by the English Act cannot but have great influence on the number of applications for divorce, as well as on their results.

(F. H. J.)

### United States.

Divorce is the termination by proper legal authority, sometimes legislatively but usually judicially, of a marriage which up to the time of the decree was legal and binding. It is to be distinguished from a decree of nullity of marriage, which is simply a legal determination that no legal marriage has ever existed between the two parties. It is also to be distinguished from a decree of separation, which permits or commands the parties to live apart, but does not completely and for all purposes sever the marriage tie. Upon the subject of divorce in the United States, and, to some extent, in foreign countries, a careful investigation has been made by the American Department of Labour, and its report, covering the years 1867 to 1886, is the main source of information. There is no reason to suspect that if the returns for the following ten or fifteen years were known they would discredit the main conclusions of the report. The number of divorces granted in the United States was in 1886 over 25,000, and unless the rate of increase has materially slackened, which is improbable, it is now 30,000. This is about equal to the number reported from all the rest of the Christian world. As divorce presupposes a legal marriage, the amount of divorce, or the divorce-rate, is best stated as the ratio between the number of divorces decreed during a year and the number of subsisting marriages or married couples. The usual basis is 100,000 married couples. In 1886 the divorce-rate in the United States was 250 to 100,000 married couples. This is equivalent to more than one divorce annually to each 2500 people. The several states differ in divorce-rate, from South Carolina (*q.v.*), with no provision for legal divorce, to some of the Rocky Mountain states, where the rate is from three to four times the average for the country. In general the rate is greater in the North than in the South, and in the West than in the East; but to this rule the New England states, Louisiana, New Mexico, and Arizona are exceptions. The New England states have a far higher rate than their geographical position would lead one to expect in accordance with the preceding statement; and the other three, owing doubtless, in part at least, to the influence of the Roman Catholic Church, have a lower rate than the states about them. The several state groups had the following divorce-rates in 1886: South Atlantic, 106; North Atlantic, 149; South Central, 296; North Central, 334; Western, 527. The divorce-rate in the United States has increased rapidly and steadily in twenty years from 173 in 1867 to 250 in 1886. But distinct tendencies are traceable in different regions. In the North Atlantic group the rate fell in twenty years; in all other groups it rose—in the North Central by 21 per cent., in the Western by 54 per cent., in the South Atlantic by 100 per cent., and in the South Central by over 200 per cent. The great increase in the South was mainly due to the spread of divorce among the emancipated negroes.

The ground pleaded for a divorce is seldom an index to the motives which caused the suit to be brought. This is determined by the character of the law rather than by the state of mind of the parties; and so far as the individuals are concerned, the ground alleged is thus a cloak rather than a clue or revelation. Still those causes which have been enacted into law by the various state legislatures do indicate the pleas which have been endorsed by the social judgment of the respective communities. In the United States there are fifty-two different jurisdictions in the matter of divorce. Six out of every seven allow divorce for desertion, adultery, or cruelty; and of the divorces reported with their causes during the twenty years, of which there were 315,547 in the United States, nearly 78 per cent. were granted for some one of these three causes, viz., 40 per cent. for desertion, 21 per cent. for adultery, and 16 per cent. for cruelty. Probably nearly 10 per cent. more were for some combination of these causes. Three other grounds for divorce are admitted as legal in many or most American states, viz., imprisonment in 39, habitual drunkenness in 38, and neglect to provide in 22. About 98 per cent. of American divorces are granted on some one or more of these six grounds. In general the legislation on the subject of the causes allowed for divorce is most restrictive in the states on the Atlantic coast, from New York to South Carolina inclusive, and is least so in the Western states. The slight expense of obtaining a divorce in many of the states, and the lack of publicity which is given to the suit, are also important reasons for the great number of decrees issued. The importance of the former consideration is reflected in the fact that the divorce-rate for the United States as a whole shows clearly, in its fluctuations, the influences of good and bad times. When times are good and the income of the working and industrial classes likely to be assured, the divorce-rate rises. In periods of industrial depression it falls, fluctuating thus in the same way and probably for the same reason that the marriage-rate in industrial communities fluctuates. In two-thirds of the divorce suits the wife is the plaintiff, and the proportion increased in the twenty years. In the Northern states the percentage issued to wives is 69, while in the Southern states it is only 55. But where both parties desire a decree, and each has a legal ground to urge, a jury will usually listen more favourably to a woman's suit.

Divorce is probably especially frequent among the native population of the United States, and among these probably more common in the city than in the country. This statement cannot be established absolutely, since statistics afford no means of distinguishing the native from the foreign-born applicants. It is, however, the most obvious reason for explaining the fact that, while in Europe the city divorce-rate is from three to five times as great as that of the surrounding country, the difference in the United States between the two regions is very much less. In other words, the great number of foreigners in American cities tend to obscure by their low divorce-rate the high rate of the native population. Divorce is certainly more common in the New England states than in any others on the Atlantic coast north of Florida, and it is not unlikely that wherever the New England families have gone divorce is more frequent than elsewhere. For example, it is much more common in the northern counties of Ohio than in the southern counties settled from the Middle Atlantic states.

There are two statements frequently made regarding divorce in the United States which do not find warrant in the statistics on the subject. The first is, that the real motive for divorce with one or both parties is the desire for marriage to a third person. The second is, that a very large proportion of divorces are granted to persons who move from one jurisdiction to another in order to avail themselves of lax divorce laws. On the first point the American statistics are practically silent, since, in issuing a marriage license to parties one or both of whom have been previously divorced, no record is generally made of the fact. In Connecticut, however, for a number of years this information was required; and, if the statements were trustworthy, the number of persons remarrying each

year was about one-third the total number of persons divorcing, which is probably a rate not widely different from that of widows and widowers of the same age. Foreign figures for Switzerland, Holland, and Berlin indicate that in those regions the proportion of the divorced who remarry speedily is about the same as that of widows and widowers. What evidence there is on the subject therefore tends to discredit this popular opinion. The evidence on the second point is more conclusive, and has gone far towards decreasing the demand for a constitutional amendment allowing a federal marriage and divorce law. About four-fifths of all the divorces granted in the United States were issued to parties who were married in the state in which the decree was later made; and when from the remaining one-fifth are deducted those in which the parties migrated for other reasons than a desire to obtain an easy divorce, the remainder would constitute a very small, almost a negligible, fraction of the total number.

It is difficult, perhaps impossible, to say how far the frequency of divorce in the United States has been or is a social injury; how far it has weakened or undermined the ideal of marriage as a lifelong union between man and woman. In this respect the question is very like that of illegitimacy; and as the most careful students of the latter subject agree that almost no trustworthy inference regarding the moral condition of a community can be derived from the proportion of illegitimate children born, so one may say regarding the prevalence of divorce that from this fact almost no inferences are warranted regarding the moral or social condition of the population. It is by no means impossible, for example, that the spread of divorce among the negro population in the South marks a step in advance from the condition of largely unregulated and illegal unions characteristic of the race immediately after the war. The prevalence of divorce in the United States among the native population, in urban communities, among the New England element, in the middle classes of society, and among those of the Protestant faith, indicates how closely this social phenomenon is interlaced with much that is characteristic and valuable in American civilization. In this respect, too, the United States perhaps represent the outcome of a tendency which has been at work in Europe at least since the Reformation. Certainly the divorce-rate is increasing in nearly every civilized country. Decrees of nullity of marriage and decrees of separation not absolutely terminating the marriage relation are relatively far less prevalent than they were in the mediæval and early modern period, and many persons who under former conditions would have obtained relief from unsatisfactory unions through one or the other of these avenues now resort to divorce. The increasing proportion of the community who have an income sufficient to pay the requisite legal fees is also a factor of great importance. The belief in the family as an institution ordained of God, decreed to continue "till death us do part," and in its relations typifying and perpetuating many holy religious ideas, probably became weakened in the United States during the 19th century, along with a weakening of other religious conceptions; and it is yet to be determined whether a substitute for these ideas can be developed under the guidance of the motive of social utility or individual desire. In this respect the United States is, as Mr Gladstone once wrote, a *tribus prœrogativa*, but one who knows anything of the family and home life of America will not readily despond of the outcome.

Bibliography.—The only important source of statistical information is the governmental report of over 1000 octavo pages, *A Report on Marriage and Divorce in the United States, 1867 to 1886, including an Appendix relating to Marriage and Divorce in Certain Countries of Europe*, by Carroll D. Wright, Commissioner of Labour. The student may perhaps obtain a copy by applying to the Commissioner of Labour. The statistics contained in this volume have been analysed and interpreted in W. F. Willcox's *The Divorce Problem: A Study in Statistics*, published by Columbia University, New York City, in 1891 and again in 1897. Further interpretations are contained in an article in the *Political Science Quarterly* for March 1893, entitled "A Study in Vital Statistics." The best legal treatise is probably Bishop on *Marriage, Divorce, and Judicial Separation.* (W. F. W.)

**Dix, John Adams** (1798–1879), American soldier and politician, was born at Boscawen, N.H., and died in New York City, 21st April 1879. His early training was military, and as a boy he participated in the war of 1812. Afterwards he studied law and was admitted to the Bar. In 1830 he became adjutant-general of New York, and was soon one of the Democratic managers of the State. From 1845 to 1849 he was a United States senator of New York. In May 1860 he became postmaster of New York City, and from 10th January until 5th March 1861 he was Secretary of the Treasury of the United States. He rendered important services in hurrying forward troops in 1861, and was appointed major-general of volunteers. In 1872 he was elected governor of New York as a Republican by a large majority, but was defeated for re-election. He had great energy and administrative ability, and became president of the Mississippi and Missouri Railway in 1853, and was first president of the Union Pacific Railway, 1863–1868.

**Dixon**, capital of Lee county, Illinois, U.S.A., on the Rock river, at an altitude of 725 feet. Its site is level and its street plan regular. It is at the intersection of branches of the Chicago and North-Western and the Illinois Central Railways. Population (1880), 3658; (1890), 5161; (1900), 7917, of whom 879 were foreign-born and 59 negroes.

**Dixon, Richard Watson** (1833–1900), English poet and divine, son of Dr James Dixon, a well-known Wesleyan minister, was born 5th May 1833. He was educated at King Edward's School, Birmingham, and on proceeding to Pembroke College, Oxford, became one of the famous "Birmingham group" there, who shared with William Morris and Burne-Jones in the Pre-Raphælite movement. He only took a second class in Moderations in 1854, and a third in *Literæ Humaniores* in 1856; but in 1858 he won the Arnold Prize for an historical essay, and in 1863 the English Sacred Poem Prize. He was ordained in 1858, was second master of Carlisle High School, 1863–1868, and successively vicar of Hayton, Cumberland, and Warkworth, Northumberland. He became Honorary Canon of Carlisle in 1874, and died at Warkworth, 23rd January 1900. Canon Dixon's first two volumes of verse, *Christ's Company* and *Historical Odes*, were published in 1861 and 1863 respectively; but it was not until 1883 that he attracted conspicuous notice with *Mano*, an historical poem in *terza rima*, which was enthusiastically praised by Mr Swinburne. This success he followed up by three privately printed volumes, *Odes and Eclogues*, 1884, *Lyrical Poems*, 1886, and *The Story of Eudocia*, 1888. Dixon's poems were during the last fifteen years of his life recognized as scholarly and refined exercises, touched with both dignity and a certain severe beauty, but he never attained any general popularity as a poet. The appeal of his poetry is addressed directly to the scholar and the man of erudition. A great student of history, his studies in that direction colour much of his poetry. He is at his best in poetic narrative, where he combines fancy and fact with much skill and grace. The romantic atmosphere is remarkably preserved in *Mano*, which is also a highly successful metrical exercise in the difficult *terza rima*. His typical

poems have charm and melody, without introducing any new note or variety of rhythm. A strong love of nature, with much felicity in interpreting natural beauty, informs all his descriptive passages. He is contemplative, sober, and finished in literary workmanship, a very typical example of the Oxford school. Pleasant as his poetry is, however, he will probably be longest remembered by the work to which he gave the best years of his life, his *History of the Church of England from the Abolition of Roman Jurisdiction*, of which at the time of his death four volumes had appeared, covering the period from 1529 to 1588. This fine work is not only built upon elaborate research, but also presents a trustworthy and unprejudiced survey of a subject in the treatment of which freedom from bias is exceedingly rare and difficult. (A. WA.)

**Dobeln**, a town of Germany, on the Mulde, 42 miles south-east by rail of the town and in the circle of Leipzig, kingdom of Saxony. There are an agricultural and a commercial school. The industries include wool-spinning, iron-founding, carriage, agricultural implement, and metal printing and stamping works. Population (1890), 13,892; (1895), 15,760.

**Dobsina** (German, *Dobschau*), a corporate town of Northern Hungary, 42 miles west by north of Kassa. The most remarkable feature in connexion with it is a large cavern some $3\frac{3}{4}$ miles to the north-west, in which is an ice-field nearly 2 acres in extent containing formations which are at once most curious and strikingly beautiful. Population, (1900), 5115.

**Dobson, Henry Austin** (1840-——), English poet and man of letters, was born at Plymouth 18th January 1840, being the eldest son of George Clarisse Dobson, a civil engineer, and on his grandmother's side of French descent. When Mr Austin Dobson was about eight years old the family moved to Holyhead, and his first school was at Beaumaris, in the Isle of Anglesea. He was afterwards educated at Coventry, and the Gymnase, Strasburg, whence he returned at the age of sixteen with the intention of becoming a civil engineer. He had a taste for art, and in his earlier years at the office continued to study it at South Kensington, at his leisure, but without definite ambition. In December 1856 he entered the Board of Trade, gradually rising to a principalship in the Harbour Department, from which he withdrew in the autumn of 1901. He married in 1868 Frances Mary, daughter of Nathaniel Beardmore of Broxbourne, Herts, and settled at Ealing. His official career was industrious though uneventful, but as poet and biographer he stands among the most distinguished of his time. The student of Mr Austin Dobson's work will be struck at once by the fact that it contains nothing immature: there are no *juvenilia* to criticize or excuse. It was about 1864 that Mr Dobson first turned his attention to composition in prose and verse, and some of his earliest known pieces remain among his best. It was not until 1868 that the appearance of *St Paul's*, a magazine edited by Anthony Trollope, afforded Mr Dobson an opportunity and an audience; and during the next six years he contributed to its pages some of his favourite poems, including "Tu Quoque," "A Gentleman of the Old School," "A Dialogue from Plato," and "Une Marquise." Many of his poems in their original form were illustrated—some, indeed, actually written to support illustrations. By the autumn of 1873 Mr Dobson had produced sufficient verse for a volume, and put forth his *Vignettes in Rhyme*, which quickly passed through three editions. During the period of their appearance in the magazine the poems had received unusual attention, George Eliot, among others, extending generous encouragement to the anonymous author. The little book at once introduced him to a larger public. The period was an interesting one for a first appearance, since the air was full of metrical experiment. Mr Swinburne's bold and dithyrambic excursions into classical metre had given the clue for an enlargement of the borders of English prosody; and, since it was hopeless to follow him in his own line without necessary loss of vigour, the poets of the day were looking about for fresh forms and variations. It was early in 1876 that a small body of English poets lit upon the French forms of Theodore de Banville, Marot, and Villon, and determined to introduce them into English verse. Mr Austin Dobson, who had already made successful use of the triolet, was at the head of this movement, and in May 1876 he published in *The Prodigals* the first original ballade written in English. This he followed by English versions of the rondel, rondeau, and villanelle. An article in the *Cornhill Magazine* by Mr Edmund Gosse, "A Plea for Certain Exotic Forms of Verse," appearing in July 1877, simultaneously with Mr Dobson's second volume, *Proverbs in Porcelain*, drew the general eye to the possibilities and achievements of the movement. The experiment was extremely fortunate in its introduction. Mr Dobson is above all things natural, spontaneous, and unaffected in poetic method; and in his hands a sheaf of metrical forms, essentially artificial and laborious, was made to assume the colour and bright profusion of a natural product. An air of pensive charm, of delicate sensibility, pervades the whole of these fresh revivals; and it is perhaps this personal touch of humanity which has given something like stability to one side of a movement otherwise transitory in influence. The fashion has faded, but the flowers of Mr Dobson's French garden remain bright and scented.

In 1883 Mr Dobson published *Old-World Idylls*, a volume which contains some of his most characteristic work. By this time his taste was gradually settling upon the period with which it has since become almost exclusively associated; and the spirit of the 18th century is revived in "The Ballad of Beau Brocade" and in "The Story of Rosina," as nowhere else in modern English poetry. In "Beau Brocade," indeed, the pictorial quality of his work, the dainty economy of eloquent touches, is at its very best: every couplet has its picture, and every picture is true and vivacious. The touch has often been likened to that of Randolph Caldecott, with which it has much in common; but Mr Dobson's humour is not so "rollicking," his portraiture not so broad, as that of the illustrator of "John Gilpin." The appeal is rather to the intellect, and the touches of subdued pathos in the "Gentleman" and "Gentlewoman of the Old School" are addressed directly to the heart. We are in the 18th century, but see it through the glasses of to-day; and the soft intercepting sense of change which hangs like a haze between ourselves and the subject is altogether due to the poet's sympathy and sensibility. *At the Sign of the Lyre* (1885) was the next of Mr Dobson's separate volumes of verse, although he has added to the body of his work in a volume of *Collected Poems* (1897). *At the Sign of the Lyre* contains examples of all his various moods. The admirably fresh and breezy "Ladies of St James's" has precisely the qualities we have traced in his other 18th-century poems; there are ballades and rondeaus, with all the earlier charm; and in "A Revolutionary Relic," as in "The Child Musician" of the *Old-World Idylls*, the poet reaches a depth of true pathos which he does not often attempt, but in which, when he seeks it, he never fails. At the pole opposite to these are the light occasional verses, not untouched by the influence of Praed, but also quite individual, buoyant, and

happy. But the chief novelty in *At the Sign of the Lyre* was the series of "Fables of Literature and Art," founded in manner upon Gay, and exquisitely finished in scholarship, taste, and criticism. It is in these perhaps, more than in any other of his poems, that we see with how much felicity Mr Dobson interpenetrates the literature of fancy with the literature of judgment. Since 1885 Mr Dobson has been engaged principally upon critical and biographical prose, by which he has added very greatly to the general knowledge of his favourite 18th century. His biographies of *Fielding* (1883), *Bewick* (1884), *Steele* (1886), *Goldsmith* (1888), *Walpole* (1890), and *Hogarth* (1879–98) are studies marked alike by assiduous research, sympathetic presentation, and sound criticism. It is particularly noticeable that Mr Dobson in his prose has always added something, and often a great deal, to our positive knowledge of the subject in question; his work as a critic has never been solely æsthetic. In *Four Frenchwomen* (1890), in the three series of *Eighteenth-Century Vignettes* (1892–94–96), and in *The Paladin of Philanthropy* (1899), which contain unquestionably his most delicate prose work, the accurate detail of each study is relieved by a charm of expression which could only be attained by a poet. In 1901 he collected his hitherto unpublished poems in a volume entitled *Carmina Votiva.* Possessing an exquisite talent of defined range, Mr Austin Dobson has, in his own words, "held his pen in trust to Art" with a service sincere and distinguished.

**Docks.**—The development within recent years of vessels of enormous carrying capacity and great speed has rendered necessary various improvements in the facilities for dealing with the traffic at different ports, including the enlargement of old docks and the construction of new ones. In tidal docks, where the shipping can be accommodated at open quays, the improvements generally consist of deepening the approaches by dredging, providing deeper water alongside the quays, and extending and enlarging the quay space. This has been the case to a large extent at such ports as Southampton, Glasgow, Dublin, and Belfast. In closed docks the chief improvements are the enlargement of old basins and the construction of entirely new ones with deeper sills and improved entrances, as at Liverpool, London, Hull, the Tyne, and various ports in South Wales and other parts of the coast.

The position, shape, and general arrangement of docks are determined by local features and the nature of the traffic carried on. At Liverpool, for instance, there are certain local features which account for the dock arrangements differing from those at many other large ports. The channel forming the approach from the sea used to be blocked at the sea end by a bar of sand on which there was a depth of water of only 10 feet at low water of spring tides, though at high water there was 40 feet; the time, therefore, during which ships could cross was limited to a few hours at high water. This, together with the great accumulation of sand in front of the docks, was apparently the reason why until the year 1873 their sills (with the exception of a few on the Birkenhead side) were not formed deeper than the level of low water of spring tides. The consequence was that the largest steamers could not enter the docks at neap tides until some of their cargo had been discharged, and vessels loading in the docks had to move into the river to complete their loading from barges. Within the last few years the bar of the Mersey has been improved by dredging, and the depth increased to 28 feet at low water of spring tides. The improvements in the docks themselves were necessary to enable the port to reap the full benefit of the deepening of the bar and to compete successfully with other places. These improvements have been chiefly at the north end, where there was most room for extension and where new large basins have been constructed. Some of the old docks have been grouped together to form large basins, new entrances and locks have been provided to suit the new arrangements of docks inside, and the sills of entrances have been lowered, the deepest being now 12 feet below low water. New and extensive graving docks have also been constructed. The Alexandra Dock, 44 acres in extent, is one of the latest and largest basins, and was designed to accommodate the biggest steamers, having special features to meet their requirements. It forms one of a line of basins opening into each other and having one common entrance from the river. Its shape is that which is found generally the most convenient for traffic, being practically rectangular, with piers projecting from one side into the

***Liverpool docks.***

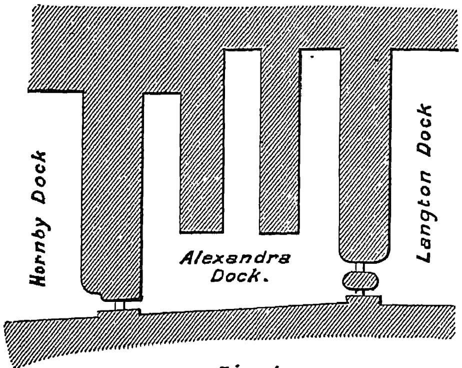

Fig 1.

water area, leaving sufficient open space near the entrance for vessels to turn. This arrangement largely increases the length of quayage (Fig. 1). In the ordinary course of trade, goods landed at the docks have to be warehoused in Liverpool, and it is found that cargoes on being discharged can be most conveniently and expeditiously dealt with by sorting them under sheds on the quays and removing them by carts to their various destinations. Hence many of the quays differ from those at most docks in not being provided with railways.

Compared with the docks on the Mersey, those on the Thames are larger in extent. They are not in one continuous line as at Liverpool, but are situated at various points on the river. The individual docks or basins are also larger than those at Liverpool. The trade at London is greater than at Liverpool taken altogether, for though the export trade is less, the import is much greater. The range of tide in the Thames is smaller than in the Mersey, and there is a deep and uninterrupted waterway from the docks to the sea. In these different circumstances the arrangements of the docks are somewhat different. The sills of the chief entrance basins are generally fixed at such a depth that ships can enter and leave them at any state of the tide, and the quays are well provided with storehouses and railways, so that cargoes can be loaded direct into railway trucks. Amongst the latest additions to the London docks are those at Tilbury, which consist of a tidal basin of 21 acres with a wide trumpet-shaped entrance to the river, having a depth of 26 feet at low water. A lock connects this basin with the main dock, which is rectangular, with a water space of about 50 acres and a depth of 38 feet at high water. From the side opposite the lock project three piers, each 350 feet wide; one is provided with a double row of storehouses, railways, &c. Parallel with the lock are two graving docks, each opening into the tidal basin and the main dock, and divided into unequal lengths by a caisson; these can be used either as four short docks, or two long docks, or two locks.

***London docks.***

Docks situated in the neighbourhood of the large coal-fields in Scotland, the North of England, and South Wales, which provide almost entirely for the loading of coals, require arrangements different from those which deal with the ordinary trade of such ports as London and Liverpool. Barry docks may be mentioned as an illustration. Entirely constructed within the last few years, and devoted almost exclusively to the export of coal, they are fitted with all the latest improvements for the accommodation of ships and for rapidly loading them with coal. In selecting the site, every natural advantage has been considered and made use of, not only for the docks themselves, but also for the approach and entrance. The latter is 80 feet wide, with a single pair of wrought-iron gates, and gives access to a basin 500 feet wide and 600 feet long. Between this basin and the main dock is a passage 80 feet wide, with a pair of gates, so that the basin is used as a large lock. The main dock is 3400 feet long by 1100 feet wide, and is divided longitudinally at one end by a wide projecting pier. Another large wet dock and two graving docks have been added, also a deep lock alongside the entrance basin. In South Wales coal is conveyed from the collieries in waggons containing about 10 tons, with a door at one end; the full waggons on arrival at the dock are shunted into sidings, and then taken one by one over a weigh-bridge to the coal-tips, which are erected on masonry towers, or on the quay walls, at intervals along the sides of the dock. At the tip the waggon enters an iron cradle or platform, which is raised or lowered and tilted as required by hydraulic power, and the coal is discharged from the end of the waggon along a shoot to the hatchway of the vessel. The empty

***Docks for coal export.***

waggon on leaving the cradle runs down an incline to a second weigh-bridge, and thence to the sidings provided for empty waggons. A similar expeditious system is adopted at other South Wales ports and at Hull, variations in the details of the tips being introduced to meet local requirements. A somewhat different method is practised on the Tyne and at other north-country ports, where there are no hoists, but the waggons, which carry about 4 tons and discharge through a door at the bottom, are brought on to the tipping staiths at a level high enough to suit any vessel. Each staith is provided with two or three spouts so as to load at two or three hatchways of a vessel simultaneously, the spouts being arranged to swing to the extent of about 15 feet on either side of their centres. Modifications of these systems are adopted at most of the various coal-ports. The speed of the coaling depends greatly upon the rapidity with which the loaded and empty waggons can be brought to and from the staiths or tips, and also upon the trimming of coal in the hold of the vessel. For loading and discharging ordinary cargoes steam or hydraulic travelling cranes are provided by some dock companies; at other docks the cargoes are worked by steam winches and derricks on the ships themselves; while at others, again, the quays are leased to various steam shipping companies, who provide their own cranes or other gear for working their cargoes.

***Dock walls.***

Dock walls may be considered as generally partaking of the nature of retaining walls. Theoretically the lateral pressure exerted by a bank of earth or other material of the same height as the wall is that due to the wedge-shaped mass, *abc* (Fig. 2), included between the vertical back of the wall *ab* and a line *bc* bisecting the angle between the vertical *ab* and *bd*, the slope of repose of the material. This, however, cannot always be entirely relied on in practice, especially in some ground, such as clay, of which the slope of repose is found to vary considerably in different circumstances. An important point in the design of dock and quay walls is the nature of the foundation, as is shown by the instances of failure which could be attributed to its defects. If the foundations are insecure, a wall is liable either to slide bodily forward at the base when the pressure of the filling is applied at the back, or the yielding of the ground under the front toe of the wall causes the top to fall forward. Conditions of the subsoil, which it is difficult, if not impossible, to foresee, have sometimes caused the failure of walls which theoretically were of more than sufficient strength. The experience of some engineers is that a dock wall should be constructed of sufficient strength to support a head of water equal to its height when the dock is empty, but it would appear that such a wall is only required in exceptional cases, and even then would fail if the foundation were not secure. In ordinary dock walls a margin of strength should always be provided to meet any weight which may be placed on the quays at the back, and this, if the foundation is good, should be sufficient for any pressure due to backing. Docks are usually constructed in estuaries and rivers where the circumstances are rarely favourable; the engineer must therefore be guided by practical experience and his own judgment, rather than rely on the ordinary calculations which might be set forth as generally applicable to retaining walls.

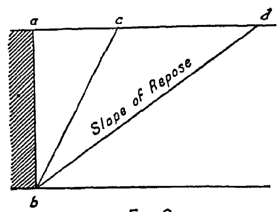

Fig. 2

***Foundations.***

As regards the foundations of walls in soft ground, if the depth of mud or silt is not excessive, and a firm foundation can be obtained beneath it, the wall should be carried down well into the solid ground. The usual course is to enclose the site of the works by a cofferdam so as to exclude the tide, and enable the foundations and other work to be constructed dry, any leakage being kept down by pumping. Where the head of water is not great and the space not limited, effectual dams can be made by embankments. When, however, a considerable head of water has to be dealt with, it becomes necessary to use timber piles driven either in a single continuous row with the joints caulked, or in a double row, with clay puddle between, and well secured by struts at the back. Timber cofferdams admit of much variety of design to suit local circumstances and to meet the varying strains to which they may be subjected. In some instances the cofferdam is partly or wholly formed by a permanent embankment or sea-wall reclaiming ground from the foreshore and enclosing the site of the works; such a method has been adopted at Leith. If the nature of the ground will not admit of a trench being excavated deep enough to afford a firm footing for the wall, this must be obtained by some other method, and the expedient most frequently adopted is to drive timber piles to carry the weight of the wall. The timber chiefly used for this purpose is pitch-pine from the states bordering the Gulf of Mexico; in comparison with the Baltic timbers it is stronger, quite as cheap, and can be obtained in longer lengths. Elm is very tough and durable; so also is beech, which has been largely used, especially when always under water or embedded in the ground. The durability of timber piles depends greatly on their situation; those which are alternately wet and dry do not last so well as those which are wholly in the ground or under water, while some soils have a more injurious effect on timber than others. Many piles have been found in good condition after being as long as 500 years in the ground. If practicable, it is advisable to drive piles until they reach hard ground. Failing this the only satisfactory way of arriving at an approximation of what they will carry is to test the ground by driving one or two piles to what is considered a sufficient depth and loading them with dead weight, from which may be determined the final set for the remainder. It has been conclusively proved that a light hammer with a high fall causes more injury, with less effective work, than a heavy hammer with a short fall. In driving piles in sand a water jet under pressure, in a pipe sunk down so that it delivers the water just below the point of the pile, loosens the sand and greatly facilitates the operation.

Cylinders constructed of brickwork have for a long time been used in India and elsewhere for foundations. At Glasgow, where they formed the foundation of part of the quay walls, they were 12 feet external and 7 ft. 4 in. internal diameter, and were tongued and grooved together (Fig. 3). The ground in which they were sunk consisted chiefly of sand and water-bearing gravel. They were 35 feet in length, and were sunk until their tops were about 2 feet above low-water level; they were then filled with concrete, and upon this foundation the upper wall was constructed. Concrete cylinders were afterwards adopted, built into groups of three, and placed as shown in plan (Fig. 4). They were made in rings 2 ft. 6 in. deep formed alternately of three and four segments so as to break bond when built together, the inside diameters being 5 ft. $9\frac{1}{2}$ in. and the outside 9 ft. $7\frac{1}{2}$ in. Under the bottom ring a cast-iron shoe was secured of the same external size and shape as the ring. This was made in six parts bolted together, and shaped to form a cutting edge. As the rings were built up, the sand and gravel were removed from within the cylinders by means of grabs or excavators. The total height of these cylinders was 28 feet, and when sunk their tops were about 3 feet below the level of low water; the average rate of sinking was about 12 inches an hour,

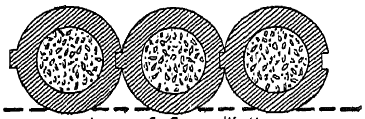

Fig 3

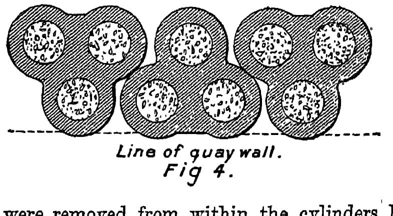

Fig 4.

and cast-iron weights amounting to 300 or 400 tons were generally required to force them down.

At Brest, where the range of spring tides is 20 feet, the foundations of the quay walls were constructed in the deep water without a cofferdam. A bank of rubble was formed up to a level of 15 feet below low water; on this large artificial blocks were placed in two courses reaching to low-water level, the part of the wall above low water being constructed in the ordinary manner by tide work. The blocks, about 100 tons in weight, and constructed of rubble masonry, were built on platforms on a slipway, and when ready for setting were lowered down the slipway sufficiently far to admit of a barge being floated over them; each was then suspended under a barge, and, as the tide rose, was lifted up and taken to the position where it was required to be set, and deposited in its place as the tide fell. In favourable circumstances this method answers well, and with slight modifications has been adopted at other ports.

At Quebec, where the time for constructing harbour works was limited to the summer months, the quay walls were formed of cribwork filled with concrete. The cribs were constructed during the winter, and in the spring were floated into position, where they rested on a foundation of bearing piles; they were then filled with concrete deposited under water. The cribs were in lengths of 40 feet, being 27 feet high, 33 feet wide at base, and 23 feet wide at top.

During the improvements and extensions executed at the port of Antwerp, it was found necessary to build on one side of the river an entirely new line of quay walls in advance of the old line, so as to secure a depth of 26 feet of water at low water and prevent the silting up caused by the irregular and broken line of the old wall. The new quay wall, which was constructed by a special system of movable cofferdams, was built of brickwork faced with stone, and was carried out in lengths of 82 feet. First an iron caisson for compressed air was provided, which was 82 feet long and $29\frac{1}{2}$ feet wide, and which varied in height from $8\frac{1}{2}$ feet to $16\frac{1}{2}$ feet according to the depth required below the bed of the river, the footings of the wall being always $26\frac{1}{2}$ feet below low water. This caisson, after serving for the removal of the soil, was filled with concrete and became an integral part of the foundation. A movable iron cofferdam 40 feet high was fixed by bolts on the top of the caisson and well strutted inside; within this the wall from the top of the foundation to low-water level could be built in the dry and in the open air, the struts being removed and replaced in the ordinary way as the work advanced. Iron tubes provided with air-locks were fixed to the top of the caisson, the wall being built round these tubes so that they could be removed when the caisson had reached the bottom and was filled in. The cofferdam was suspended complete by chains from an iron framework carried on two iron barges, and was raised or lowered by hoisting-gear. The site for the caisson was first prepared by dredging. The caisson with cofferdam attached was then fixed in place by means of the floating barges, and sunk by the weight of the work being carried on above and within it. The narrow spaces between the lengths of wall thus built were filled in afterwards by an arrangement which effectually tied together the whole wall.

*Walls.*

Dock walls are usually now constructed of Portland cement concrete, mixed in proportions varying from 5 to 8 parts of shingle and sand to 1 part of cement, the sand being in the proportion of from $1\frac{1}{2}$ to $2\frac{1}{2}$ parts to 1 part of cement according to the quality required. The interstices of ordinary shingle without sand form about 33 per cent. of its bulk, and they should be completely filled by the cement and sand when mixed. To ensure good work the cement must be of the highest quality, and the other materials must be perfectly clean. Broken stone is sometimes substituted for shingle, and some engineers use large fragments of stone bedded in the mass of the concrete. Care should be taken to make the concrete as compact and solid as possible, in order to prevent the percolation of water, since concrete is liable to damage from sea-water in course of time if this precaution is not observed. The upper portion of the wall, where it is exposed to the rubbing of ships and boats lying alongside, should be faced with masonry or timber fendering. Some quay walls are constructed entirely of timber, the filling at the back being retained by sheet piling up to about low water, and above that level by a paved slope. A slight batter or slope—from 1 in 8 to 1 in 12 is that usually given—to the face of a wall adds to its strength and appearance. Where the range of tide is great, the walls should be vertical or with a very slight batter, since the fall of the tide will otherwise cause the side of the ship to be an inconvenient distance away from the line of the coping.

***Graving docks.***

Later improvements in the design of graving docks consist chiefly in the increased dimensions, the facilities for moving the gates and caissons at their entrances, and the arrangements for pumping out the water. With the increasing size of vessels, it has become necessary to provide larger dry docks in which repairs to such ships may be carried out. In all the most important ports new and extensive graving docks have been constructed. The following are the lengths of some of the largest: Liverpool, 1000 feet; Southampton, 750 feet; Glasgow, 880 feet; Belfast, 850 feet; Barry, 740 feet; Tilbury, 875 feet. Some of the longest graving docks are provided with a caisson or gates, dividing them into two lengths, so that for a short vessel only a part of the dock need be used. The construction of a graving dock requires great care, especially if the ground is of a soft or treacherous nature. If soft ground, such as sand or silt, extends to some depth below the bottom of the dock, and the depth to hard ground is so great as to render the removal of the soft material impracticable, it will be necessary to enclose the site by sheet piling to prevent any movement of the subsoil through scour. This should be done in addition to any piling that may be required to carry the floor and side walls, and is necessary under the entrances of both wet and graving docks; for if water finds its way under the entrance with the pressure due to the head of water on either side of the gates, it will cause a scour, and sooner or later the destruction of the entrance will follow. When the site has been excavated and prepared, and suitable drains have been provided for drawing off any water that may be met with, the foundations for the floor and side walls have to be constructed. For this class of work Portland cement concrete has almost entirely superseded brickwork where suitable materials for concrete can be obtained. The floor of a graving dock is in principle an inverted arch, which has to resist the upward pressure of any water that may penetrate to the under-side, and as such water will also be equally at the back of the walls, they will be subjected to a similar pressure in addition to the lateral pressure due to the filling. This fact should be regarded in putting in the concrete, which should be constructed in sections to the full depth of the floor, with the longitudinal vertical joints radiating as if the surface of the invert were curved (Fig. 5). When the concrete is in contact with rock, the joint should be broken by trenches cut into the surface of the rock, to which the concrete is thus firmly keyed; this is of especial importance if the rock is of a water-bearing nature. The surface of the floor is generally formed of granite masonry bedded on the concrete, deeper stones being placed along the centre to carry the blocks, while the sides are sometimes paved with granite setts, or blue bricks, or, as in the case of a dock at Halifax, N.S., with pitch-pine planking fixed to longitudinals bedded in the concrete. Usually the centre of the floor is kept a few inches higher than the sides, to allow the water to draw off. The blocks on which the keel of the vessel rests when in dock are fixed along the centre of the floor, and are constructed of hard wood, or of cast-iron and wood combined, the parts of

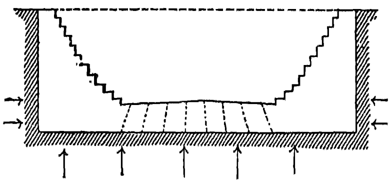

Fig. 5

each block being formed wedge-shaped so as to be easily adjusted to any required height. There is considerable variety in the shape and arrangement of the side walls of graving docks, but they must be strong enough to bear any pressure that may be applied to them as training walls. The faces are constructed in steps, or altars as they are termed (Fig. 5), on which rest the shores which support a vessel in the dock. Steps are constructed in suitable positions for access to the bottom, also slides down which timber and other materials can be lowered. These side walls are usually of concrete faced with stone; in some docks the facing is formed of concrete of extra quality, and in others of blue bricks with copings of stone. The entrances are constructed with side walls and sills to suit the method adopted for closing the dock, gates requiring a different arrangement from that provided for a caisson. Culverts fitted with penstocks are built in the side walls near the entrances, for filling the dock with water. For emptying, centrifugal pumps seem on the whole the most convenient and the least liable to be affected by the passage of small chips of wood, which cannot always be avoided even with the greatest care. When arrangements have to be provided for keeping the entrance clear of mud occasional dredging is generally resorted to. At Liverpool an extensive system of sluicing is adopted, the head of water retained in the dock or closed basin as the tide falls being utilized to produce a strong current which carries off the mud. At Tilbury jets of water under pressure, combined with an arrangement of harrows, are applied at ebb tide to the bottom of the dock and entrance, from an apparatus attached to a floating craft which can be moved to any part required; the mud stirred up by the harrows is set in motion by the jets, and carried away by the ebb tide.

***Timber docks.***

Hitherto most of the dry docks for the United States Government have been constructed of timber, those of masonry having been considered too expensive. In the navy yards of Charlestown, Brooklyn, and Norfolk there are masonry docks, the sills of which are 25 feet below high-water spring tides; in the timber docks at the various yards the sills are from 15 to 22 feet below high water. A report on the relative value of timber and masonry for dry docks by Commodore Endicott, U.S. Navy, chief of the Bureau of Yards and Docks, states that timber docks are temporary structures, and that the wood of which they are built requires extensive renewal at the end of 25 years, practically amounting in some instances to rebuilding; also that accidents have occurred from the partial collapse and bursting of the floor and sides of some of the timber docks. He considers that, in view of the increased depth required in new docks to accommodate vessels of large draught, the risk to their stability will be largely increased, as they will be subjected to more unfavourable conditions, in particular to a much greater hydrostatic pressure, and that freedom from such risk can only be obtained from a masonry structure designed to resist by its own weight the dangerous force to which it is subjected. He recommends that any new docks should be constructed, not of timber, but of masonry and concrete combined; and that instead of being constructed by day labour and by Government employees, they should be carried out by contract, which would be the means of greatly reducing their cost.

***Dock gates.***

Dock gates are constructed of timber or iron. The two doors are exactly similar, each being rather longer than half the width of the entrance, so that when they meet in closing their faces form two sides of a triangle whose base is the straight line drawn from one heel post to the other (Fig. 6). The distance from the apex or meeting-point to the base, which is termed the rise of the gates, is a matter of considerable importance, as affecting the strains on the gates themselves and on the masonry, to which the strains are transmitted at the heel posts; in practice it varies from one-sixth to one-fourth of the width of entrance. The heel post is vertical, and shaped to form a tight joint with the closing face of the

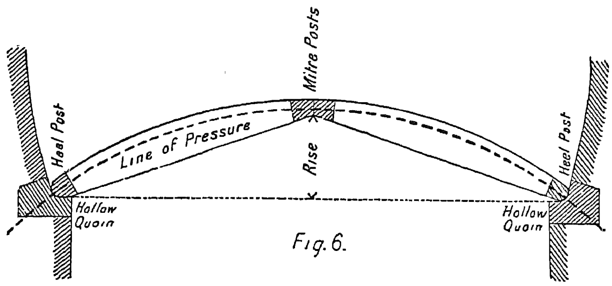

Fig. 6.

hollow quoin; at the bottom is fixed a cast-iron socket which rests upon a cast-iron pivot firmly secured to the masonry of the gate platform, the top being held by an iron strap passing round it and securely anchored to the masonry of the side walls. The main beams of each gate are built into and secured to the heel post at one end and to the mitre post at the other end; the two mitre posts constitute the meeting face of the pair of gates, and should form a tight and even joint from top to bottom. The timber generally used for gates is greenheart, which is durable and not liable in Britain to the attacks of sea-worms. When gates are made of iron the closing faces at sills, mitre posts, and heel posts are formed of timber to ensure close-fitting joints. The gates when open fit back into recesses formed in the side walls. Timber gates are less liable to injury or twisting, and are more easily fitted together than iron gates; on the other hand, the latter can be easily rendered buoyant by the introduction of air chambers, which reduce the strain on the hinges and the weight on the rollers supporting the outer end. These rollers are fixed so that they can be adjusted as required to support the gate, and work on a circular iron way attached to the masonry of the gate platform; they are not necessary for gates where the entrance is less than 60 feet wide. The pressure on a gate is due to the difference in level of water on the inside and outside surfaces; this has to be withstood and conveyed to the side walls by the structure of the gates. The strains in any gate are those of an arch with the load applied in radial lines and equally distributed (Fig. 6). A pair of gates should form part of a circular dam, and should be so designed that the line of pressure approximates to a line forming the arc of a circle passing through the centres of the heel posts and the centre of the meeting face of the mitre posts, to ensure that the gates are subject to compressive stress only. For convenience a pair of gates are usually shaped so that their outside faces when closed form a continuous curve, with the inside faces straight. The subject of strains in dock gates has been most fully dealt with in a paper by Mr A. F. Blandy (*Proc. Inst. C. E.* vol. lviii.), and by Mr J. M. Moncrieff (*ib.* vol. cxvii.), to which the reader is referred for information. For moving dock gates an opening and a closing chain is attached to the outer and inner faces respectively of each gate as low down as can be arranged. The chains are conducted to the back of the side walls through openings, and are worked mostly by hydraulic power. At Barry, Leith, and other ports a more rapid and simple arrangement has been introduced by attaching the piston of a hydraulic engine direct to the back of each gate (Fig. 7). The gate thus closed is held up firm against any undulation of the water outside, and the chains are done away with, together with the necessary guiding sheaves. Instead of gates caissons

are frequently used, and are of two types—floating and sliding. The former, when the entrance is opened, is floated out of its position, while the latter is drawn endways into a chamber constructed at the side of the entrance, being moved over ways with plane sliding surfaces, or on rollers fixed either to the masonry or to the bottom of the caisson. The advantages of caissons are that they save room by shortening the length of the entrance, they dispense with hollow quoins, they facilitate maintenance and repairs, and, by being capable of carrying a road or railway along their top, they do away with the cost and inconvenience of a swing bridge across the entrance. The deck forming the roadway on top of the sliding caisson can be so arranged that it falls automatically as the caisson is drawn into the chamber, and rises again when it is moved out. Caissons are raised and lowered by the aid of air and water chambers, the water being ejected or admitted by pumps. Sliding caissons are constructed of rectangular section, and are drawn backwards and forwards by hauling gear fixed at the inner end of the caisson chamber and worked by steam, compressed air, or hydraulic power, the weight of the caisson on the sliding ways or rollers being adjusted by the amount of water admitted to the water chambers. Floating caissons are in shape somewhat similar to the hull of a ship, with a width at the top varying according to the nature of the road or footway required along it.

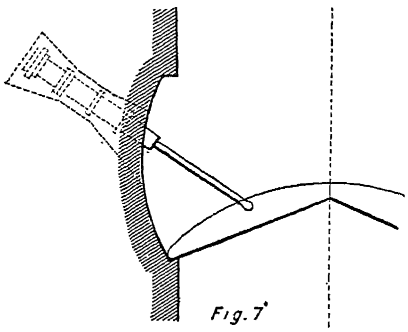

Fig. 7

Floating and pontoon docks are constructed in various forms, but their function is in every case to lift a vessel out of the water and support it by means of their buoyancy. They can only be used in completely sheltered positions. Circumstances, such as a bad foundation, which might render the construction of a solid dock almost if not quite impracticable, would favour the adoption of a floating dock, but each case must be judged on its own merits.

# DOCKYARDS.

## 1. British.

*Recent Structural Developments.*—The extensions of H.M. dockyards at Portsmouth and Chatham, described in the ninth edition article on Dockyards, marked the most important stage in the history of dockyard construction which had been reached up to the date of their completion and prior to the year 1880. It is proposed to describe briefly in the present article the extent to which H.M. dockyards have developed since that date, with special reference to the great works which were sanctioned by the Naval Works Acts of 1895 and subsequent years.

**Under special legislation.**

The works proposed under these Acts are classified under three heads, viz., (*a*) the enclosure and defence of harbours against torpedo attack; (*b*) adapting naval ports to the present needs of the fleet; (*c*) naval barracks and hospitals. Under the first heading are included the defensive harbours at Portland, Dover, and Gibraltar; under heading (*b*) are included the deepening of harbours and approaches, the dockyard extensions at Gibraltar, Keyham, Simons Bay, and Hong-Kong, with sundry other items. Under heading (*c*) are included the naval barracks at Chatham, Portsmouth, and Keyham; the naval hospitals at Chatham, Haslar, and Haulbowline; the colleges at Keyham and Dartmouth, with other items. The total estimated cost of these works, as stated in the Act of 1899, amounts to upwards of twenty-three and a half millions sterling, and they will form, when completed, the most important additions yet made at any one period to the dockyard and harbour works required to meet the necessities of the fleet. These works will now be briefly described under the headings of their various localities, together with the principal additions to other dockyards carried out between 1880 and 1901.

### (*a*) *Enclosure and Defence of Harbours against Torpedo Attack.*

*Portland.*—The existing harbour of refuge at this station was commenced in 1847 under the direction of the Admiralty, and completed about fifteen years later in the form and extent in which it remained up to the date of the commencement of the additional works now being carried out. The original design consisted of the partial enclosure of an extensive area of water bounded on the south and west by the island of Portland and the adjacent coast, and sheltered thereby from winds from those quarters, and on the east by a breakwater of large dimensions starting from the north-east corner of Portland island. This breakwater consisted of a rubble mound of stone quarried by convict labour at the summit of the island, lowered by a wire-rope incline to the sea-level, and deposited by means of staging in its position in the mound. The breakwater consisted of two portions, an inner arm terminating in a masonry head and fort, and an outer or detached breakwater terminating in a circular fort at its northern extremity, an entrance for shipping being left between the two. The enclosure thus formed afforded a magnificent sheltered roadstead of great extent, with a depth of water of not less than thirty feet over a large proportion of the area.

The developments of naval strategy and the necessity of greater protection from torpedo attack have, however, led to additional works. It will have been observed from the foregoing remarks that the harbour, while protected on the west, south, and east sides, was still open on the north to Weymouth bay and the Channel. It is therefore to the further and complete enclosure of the roadstead on this northern side that the additional works have been directed (Fig. 1). The distance from the circular fort at the extremity of the eastern breakwater above described to the Bincleaves rocks on the western shore of the harbour is about two miles. This opening is now closed by two additional breakwaters, one portion being detached and about 4465 feet in length, the other starting from the Bincleaves shore and about 4642 feet in length. Each breakwater consists of a rubble mound of stone, quarried as before on the summit of the island, lowered by wire-rope incline, shipped into specially designed hopper barges, towed out and deposited on the site of the breakwaters, which have thus been brought up from the sea bottom to above the water-line in depths of water ranging from 30 to 50 feet. Each section of breakwater

is terminated by a masonry head with beacon light, and two entrances, each 700 feet in width, serve for the navigation of shipping in entrance and exit. The defensive harbour thus completely enclosed, partly by natural means, partly by the great artificial works now carried out, covers an area of 2200 acres to the one-fathom line, of which 1500 acres have a depth of not less than 30 feet at low water, and is probably one of the finest artificial harbours in the world. There is no dockyard at Portland, but the watering and coaling appliances for the supply of the fleet are of considerable importance and extent, the latter having lately been greatly improved by the construction of a coaling jetty and camber for the storage of both sea-borne and land-borne coal and its handling by modern hydraulic appliances.

*Dover.*—The Admiralty pier at Dover, so familiar to passengers by this route to or from the Continent, was the first instalment of the scheme for a large harbour of refuge recommended by the Royal Commissions of 1844–45. This pier was commenced in 1847, and practically completed in 1871, having a total length of about 2000 feet. As an engineering structure it has proved successful, as, with the exception of the destruction of the parapet in 1877, no material damage has been caused by the heavy seas to which it has constantly been exposed. The remainder of the scheme was not, however, completed. The Royal Commission of 1881 on the employment of convicts again recommended the construction of a large harbour at Dover, but beyond the erection of a convict prison nothing further was done for some years. In the meanwhile the Dover Harbour Board, with a view to improving the existing condition of the port, commenced the scheme indicated on the plan and entitled the "commercial harbour," consisting of an east pier, which runs parallel to the general direction of the Admiralty pier, and will ultimately enclose in conjunction with the latter a sheltered water area of some 75 acres. This work was commenced in 1893, and is now approaching completion. The enclosed harbour for the accommodation of H.M. navy, for which funds were voted by Parliament in 1895 and subsequent years, is indicated on the plan. It will be seen that the water area enclosed amounts to 610 acres, exclusive of the commercial harbour, of which 322 acres have a depth of not less than 30 feet at low water. The enclosing breakwaters are three in number, the most westerly one being an extension in a south-easterly direction of the existing Admiralty pier for a length of 2000 feet; the southern breakwater is isolated, and is 4200 feet in length, curving round shorewards at its eastern end to accord with the direction of the third breakwater, which forms the eastern boundary of the harbour; the last starts from the shore at a point somewhat east of the convict prison, and runs southerly for a length of 3320 feet.

These three breakwaters, with a united length of rather more than $1\frac{3}{4}$ miles, are each built of massive concrete blocks in the form of a practically vertical wall, founded upon the solid chalk and rising to a quay level of 10 feet above high water Two entrances, one 800 feet and the other 600 feet in width, are provided in the positions shown on the plan. The foreshore at the foot of the cliffs between the Castle jetty and the root of the eastern breakwater is in process of reclamation by means of a massive sea-wall founded upon the chalk. These great works were begun in 1897 (Fig. 2).

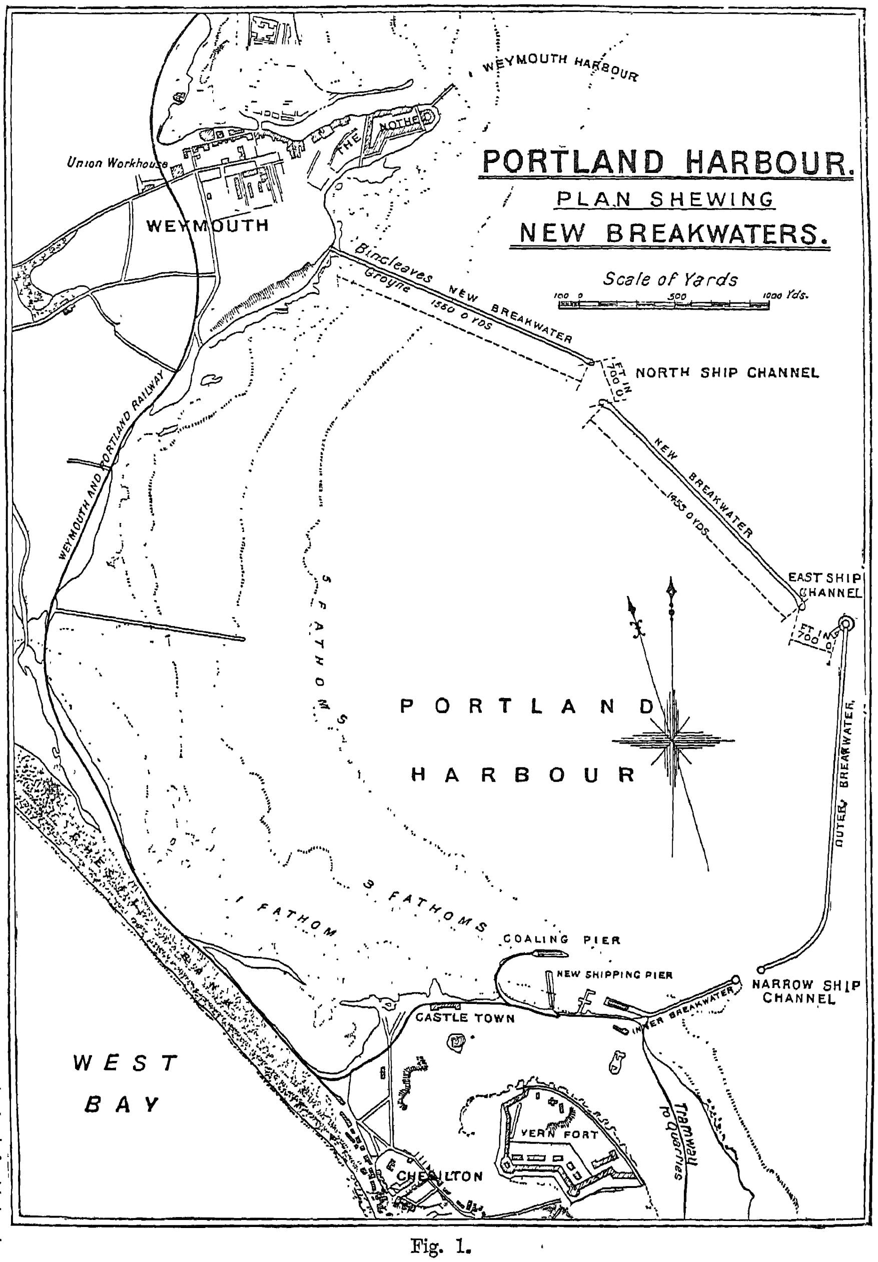

Fig. 1.

*Gibraltar.*—The details of the defensive harbour here are closely connected with the general scheme of dockyard extension, and will be found described under the reference to Gibraltar which follows. The enclosed water area at Gibraltar is less than that at Dover in the proportion of about 440 to 610 acres, but neither harbour is comparable with Portland in area.

### (b) *Adapting Naval Ports to the Present Needs of the Fleet.*

*Gibraltar.*—The history of British naval dockyards is in general one of continuous development, extending over considerable periods of time, and reflecting in the various stages of that history the naval requirements, the engineering skill, and the mechanical resources and appliances of the day. As these have developed and increased, so the older and more obsolete portions and appliances of the yards have been from time to time renewed and readapted to meet modern exigencies; and the result exhibits the constantly increasing effort to meet the demands which modern naval architecture and strategy are as constantly renewing. In the case, however, of the great works at Gibraltar we have the somewhat unique example of the creation of a modern dockyard of the first class, as it were, at a stroke, as the small existing yard will have become entirely absorbed in the new extension works. The absence of any dry dock at Gibraltar had been for some time the occasion of considerable public discussion, and a commission was appointed in 1890 to consider the question. But the recommendations of this commission became greatly amplified in the scheme finally approved by the Admiralty, for which funds were provided in the Naval Works Loan Act of 1895 and subsequent years. This scheme may be said to consist of two principal parts: the construction of a dockyard with ample dry dock accommodation, with the necessary workshops, stores, and offices; and the construction of a great defensive harbour of sufficient extent to shelter a powerful fleet, and yielding largely increased coaling and wharfage accommodation. Combined with the defensive harbour, and forming an integral part thereof, is the new commercial mole, a portion of the cost of which is borne by the colony (Fig. 3).
